**Reactions.**—1. Heated in air or oxygen,  $\text{Sb}_2\text{O}_3$  is formed.—2. Conc. hot nitric acid oxidises to  $\text{Sb}_2\text{O}_3$  and  $\text{Sb}_2\text{O}_5$ ; it dissolves in cold fuming  $\text{HNO}_3$  and forms  $\text{Sb}_2\text{O}_5 \cdot \text{N}_2\text{O}_5$  (Peligot, *C. R.* 23, 709).—3. Treated with fuming sulphuric acid, small lustrous crystals are obtained, which, after drying for six months in contact with burnt clay have the composition  $\text{Sb}_2\text{O}_5 \cdot 2\text{SO}_3$ ; by treating these crystals with  $\text{H}_2\text{O}$  the salt  $\text{Sb}_2\text{O}_5 \cdot \text{SO}_3$  is obtained (Peligot, *l.c.*). Schultze-Sellack (*B.* 4, 13) describes the salt  $\text{Sb}_2\text{O}_5 \cdot 3\text{SO}_3$  ( $= \text{Sb}_2\text{O}_5 \cdot 6\text{SO}_3$ ) as long lustrous needles obtained by evaporating solutions of  $\text{Sb}_2\text{O}_3$  in fairly conc.  $\text{H}_2\text{SO}_4$ ; this salt is unchanged in dry air, but gives off  $\text{SO}_3$  on heating, and is decomposed by water.  $\text{Sb}_2(\text{SO}_4)_3$  is also formed by dissolving  $\text{Sb}_2\text{S}_3$  in hot conc.  $\text{H}_2\text{SO}_4$  (Hensgen, *l.c.* *T. C.* 4, 401) (*v. SULPHATES*).—4.  $\text{Sb}_2\text{O}_3$  dissolves in solution of potassium-hydrogen tartrate, forming the salt  $\text{C}_4\text{H}_4\text{K}_2\text{SbO}_6$ , which is probably the K salt of the acid  $\text{Sb}_2\text{C}_4\text{H}_4\text{O}_6 \cdot \text{OH}$  (*v. Clarke and Stallo, B.* 13, 1787).—5.  $\text{Sb}_2\text{O}_3$  acts as a reducing agent towards salts of silver, gold, &c. (*v. ANTIMONY, DETECTION OR, Antimonious compounds*).—6.  $\text{Sb}_2\text{O}_3$  does not directly combine with water, but two hydrates have been prepared:—(a)  $\text{Sb}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ , by adding  $\text{CuSO}_4$  to  $\text{Sb}_2\text{S}_3$  dissolved in  $\text{KOH}$  until the filtered liquid gives a white pp. ( $\text{Sb}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ ) on addition of an acid (Presenius; *v. also Schaffner, A.* 51, 182); (b)  $\text{Sb}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ , a white powder which begins to lose water above  $150^\circ$ , obtained by the spontaneous decomposition of an aqueous solution of the acid  $\text{H}_2\text{C}_2\text{H}_2\text{SbO}_6$  obtained by decomposing  $(\text{C}_2\text{H}_3\text{SbO}_6)_2\text{Ba}$  by the proper quantity of  $\text{H}_2\text{SO}_4$  (Clarke and Stallo, *B.* 13, 1793).—7. Dissolves in boiling antimonious chloride to form oxychlorides;  $\text{SbOCl} \cdot 7\text{SbCl}_3$  is described by Schneider (*P.* 108, 407).

**II. ANTIMONIC OXIDE**  $\text{Sb}_2\text{O}_5$  (*Antimonic acid*). Mol. w. unknown. S.G. 3.78 (Playfair a. Joule, *C. S. Mem.* 3, 83).

**Preparation.**—By dissolving powdered Sb in aqua regia, or conc.  $\text{HNO}_3$ , evaporating to dryness, and heating [not above  $275^\circ$ ] (Geuther, *J. pr.* [2] 4, 438; Dubrawa, *A.* 186, 110).

**Properties.**—Citron-yellow powder; insoluble in water, but reddens moist blue litmus paper; loses O at  $300^\circ$  (Geuther, *l.c.*) giving  $\text{Sb}_2\text{O}_3$ ; soluble in conc.  $\text{HCl}$ , slightly soluble in conc.  $\text{KOH}$ .

**Reactions.**—1. Heated with antimony or antimony sulphide,  $\text{Sb}_2\text{O}_3$  is formed.—2. Heated in chlorine,  $\text{SbCl}_3$  and  $\text{Sb}_2\text{O}_3$  are produced.—3. Heated with ammonium chloride, is completely volatilised.—4. Reacts with alkaline carbonates on fusion, with evolution of  $\text{CO}_2$  (*v. further ANTIMONY, DETECTION OR, Antimonic compounds*).—5. Hydrates are not produced by the direct action of water, but indirectly the three compounds,  $\text{Sb}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ ,  $\text{Sb}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ , and  $\text{Sb}_2\text{O}_3 \cdot \text{H}_2\text{O}$ , have been obtained (*v. ANTIMONY, ACIDS OF, Antimonates*). Forms many compounds with  $\text{WO}_3$  and  $\text{MoO}_3$  (*v. Gibbs, C. N.* 48, 355; *Am. T.* 209 and 313).

**III. ANTIMONOSO-ANTIMONIC OXIDE**  $\text{Sb}_2\text{O}_4$  (*Antimony tetroxide*). Mol. w. unknown. S.G. 4.074 (Playfair a. Joule, *C. S. Mem.* 3, 83); 6.5 (Boullay, *A. Ch.* [2] 43, 266). S.H. ( $23^\circ$ – $90^\circ$ ) 0.9535 (Regnault, *A. Ch.* [3] 1, 129).

**Occurrence.**—Native, as *Antimony-ochre*.

**Preparation.**—1. By heating  $\text{Sb}_2\text{O}_3$  in air.—2. By oxidising  $\text{Sb}$ ,  $\text{Sb}_2\text{O}_3$ , or  $\text{Sb}_2\text{S}_3$ , by conc.  $\text{HNO}_3$ , evaporating to dryness, and strongly heating.

**Properties.**—White powder, becoming yellow on heating; has not been melted or volatilised; insoluble in water, but reddens moist blue litmus paper; very slightly acted on by acids.

**Reactions.**—1. Heated with solution of cream of tartar,  $\text{Sb}_2\text{O}_4 \cdot x\text{H}_2\text{O}$  remains and solution contains  $\text{C}_4\text{H}_4\text{KSbO}_6$ .—2. Solution in  $\text{HCl}$  dropped into water, is decomposed into  $\text{Sb}_2\text{O}_3$  and  $\text{Sb}_2\text{O}_5$ .—3. Heated with antimony  $\text{Sb}_2\text{O}_4$  is formed.—4. With molten potash forms  $\text{K}_2\text{O} \cdot \text{Sb}_2\text{O}_4$  (*v. ANTIMONY, ACIDS OF; ANTIMONOSO-ANTIMONATES*); solution of this in water slowly reduces  $\text{AgNO}_3$  and  $\text{AuCl}_3$ .  $\text{Sb}_2\text{O}_4$  reacts as a compound of  $\text{Sb}_2\text{O}_3$  and  $\text{Sb}_2\text{O}_5$  ( $= \text{Sb}_2\text{O}_4$ ); it is sometimes regarded as antimony antimonate ( $\text{SbO})\text{SbO}_3$ , derived from  $\text{HSbO}_3$ .

**Antimony, oxybromides of.** Two oxybromides are obtained by the action of  $\text{H}_2\text{O}$  on  $\text{SbBr}_3$ , viz.  $\text{Sb}_2\text{O}_3 \cdot \text{Br}_2$  and  $10\text{Sb}_2\text{O}_3 \cdot \text{Br}_2 \cdot \text{SbBr}_3$ ;  $\text{SbOBr}$  is probably formed by the action of sunlight on  $\text{SbBr}_3$  in  $\text{CS}_2$  (*v. ANTIMONY, BROMIDE OF*).

**Antimony, oxychlorides of.** At least six compounds are known;  $\text{SbOCl}$ ,  $\text{SbOCl} \cdot 7\text{SbCl}_3$ ,  $\text{Sb}_2\text{O}_3 \cdot \text{Cl}_2$ , and  $10\text{Sb}_2\text{O}_3 \cdot \text{Cl}_2 \cdot \text{SbCl}_3$ , obtained from  $\text{SbCl}_3$ ;  $\text{Sb}_2\text{O}_3 \cdot \text{Cl}_2$  and  $\text{SbOCl}$ , from  $\text{SbCl}_3$ .

When  $\text{SbCl}_3$  is added to a little water,  $\text{SbOCl}$  is obtained (sometimes mixed with  $\text{SbCl}_3$ ). This oxychloride seems to exist either as a white amorphous powder, or as monoclinic crystals isomorphous with  $\text{SbOCl}$  (Cooke, *P. Am. A.* [2] 5, 72); the crystals are best obtained by using 10 pts.  $\text{SbCl}_3$  and 17 pts.  $\text{H}_2\text{O}$ , allowing to stand for a day or two, pressing, and washing with ether (Sabanajew, *Bl.* [2] 16, 79); the amorphous powder is best prepared by adding 3 pts.  $\text{H}_2\text{O}$  to 1 pt.  $\text{SbCl}_3$ , filtering at once, drying over  $\text{H}_2\text{SO}_4$ , and washing with ether. Crystalline  $\text{SbOCl}$  is also obtained by heating  $\text{SbCl}_3$  with  $\text{C}_2\text{H}_5\text{O}$  (in ratio  $\text{SbCl}_3 \cdot \text{C}_2\text{H}_5\text{O}$ ) in a closed tube to  $160^\circ$  (Schäffer, *A.* 152, 314). By the action of much water on  $\text{SbCl}_3$  (5 to 50 parts to 1 part  $\text{SbCl}_3$ , according to Sabanajew, *l.c.*) the oxychloride  $\text{Sb}_2\text{O}_3 \cdot \text{Cl}_2$  is obtained as an amorphous powder, which becomes crystalline on standing. To prepare the crystalline forms it is best to use 30 parts of cold water, or 3 parts of water at  $60^\circ$  to  $70^\circ$  (in the latter case allowing the pp. to remain a few hours before collecting); there are some differences in the forms of the two sets of crystals (Sabanajew, *l.c.*). Crystals (trimetric Schäffer, *A.* 152, 314; monoclinic, Cooke, *P. Am. A.* [2] 5, 72) of  $\text{Sb}_2\text{O}_3 \cdot \text{Cl}_2$  are also obtained by heating  $\text{SbCl}_3$  with  $\text{C}_2\text{H}_5\text{O}$  (in ratio  $\text{SbCl}_3 \cdot 3\text{C}_2\text{H}_5\text{O}$ ) to  $140^\circ$ – $150^\circ$  (Schäffer, *l.c.*). The compound  $\text{Sb}_2\text{O}_3 \cdot \text{Cl}_2$  is also produced by the action of alcohol on  $\text{SbOCl}$  (Schneider, *P.* 108, 407); and also by heating dry  $\text{SbOCl}$  ( $5\text{SbOCl} = \text{Sb}_2\text{O}_3 \cdot \text{Cl}_2 + \text{SbCl}_3$ ; Sabanajew, *l.c.*).

The product of the action of much  $\text{H}_2\text{O}$  on  $\text{SbCl}_3$  is known as *powder of Algaroth*; the composition varies according to temperature, quan-

ality of water, and quantity of HCl in the solution of  $\text{SbCl}_3$ , used (comp. Duflos, *S.* 67, 268; Johnston, *J.* pr. 6, 55; Malaguti, *J.* pr. 6, 253; Peligot, *A.* 64, 280).

According to Williams (*C. N.* 24, 224) the action of hot water on  $\text{SbCl}_3$  produces  $10\text{Sb}_2\text{Cl}_2\text{O}_3 \cdot \text{SbCl}_3$ ; Williams also describes two oxychlorides obtained by heating  $\text{Sb}_2\text{O}_3$  with  $\text{SbCl}_3$  ( $\text{Sb}_2\text{O}_3 \cdot 3\text{SbCl}_3$ ) to  $140^\circ$  in a closed tube;  $\text{Sb}_2\text{OCl}_2$ , M.P. =  $85^\circ$ , and  $\text{Sb}_2\text{O}_2\text{Cl}_2$ , M.P. =  $97.5^\circ$ .

Cooke (*P. Am. A.* [2] 5, 72) describes another oxychloride  $\text{Sb}_2\text{O}_2\text{Cl}_2$ ; and Schneider (*P.* 108, 407) two others,  $\text{SbOCl} \cdot 7\text{SbCl}_3$  and  $2\text{SbOCl} \cdot \text{Sb}_2\text{O}_3$ .

According to Thomsen (*Th.* 2, 240) the heat of formation of  $\text{Sb}_2\text{O}_2\text{Cl}_2$  from  $\text{SbCl}_3$  and  $\text{Aq}$  is 8910 gram-units (v. also Guntz, *C. R.* 98, 512). By dropping the calculated quantity of very cold water on to  $\text{SbCl}_3$ , Dubrawa (*A.* 184, 118) obtained  $\text{SbOCl}_2$  ( $\text{SbCl}_3 + \text{H}_2\text{O} = \text{SbOCl}_2 + 2\text{HCl}$ ); this oxychloride is a yellowish, somewhat crystalline, mass, soluble in alcohol; it deliquesces to a yellow liquid, from which needle-shaped crystals separate in dry air. When heated it melts and decomposes (probably to  $\text{SbOCl} + \text{Cl}_2$ ). It is decomposed by  $\text{Na}_2\text{CO}_3\text{Aq}$  ( $2\text{SbOCl}_2 + 3\text{Na}_2\text{CO}_3\text{Aq} = 6\text{NaClAq} + 2\text{O} + 3\text{CO}_2 + \text{Sb}_2\text{O}_3$ ).

**Antimony, oxyfluoride of.**  $3\text{SbOF} \cdot \text{SbF}_3$ , obtained by deliquescence of  $\text{SbF}_3$  (v. ANTIMONY, FLUORIDES OF).

**Antimony, oxyiodides of.**  $\text{Sb}_2\text{O}_2\text{I}_2$  and  $\text{SbOI}$ .  $\text{Sb}_2\text{O}_2\text{I}_2$  is obtained as light yellow crystals by evaporating a solution of  $\text{SbCl}_3$  in  $\text{KI Aq}$ , adding  $\text{H}_2\text{O}$  and evaporating again. The composition of the oxyiodide obtained by the action of  $\text{H}_2\text{O}$  on  $\text{SbI}_3$  varies according to the conditions of its preparation; by pouring  $\text{SbI}_3$  in  $\text{HIAq}$  into hot  $\text{H}_2\text{O}$ ,  $\text{Sb}_2\text{O}_2\text{I}_2$  is obtained (v. Macivor, *C. J.* [2] 14, 328). By the action of air and sunlight on  $\text{SbI}_3$  in  $\text{CS}_2$ , both oxyiodides are formed, production of  $\text{SbOI}$  proceeding rapidly (Cooke, *P. Am. A.* [2] 5, 72). When  $\text{SbOI}$  is heated in a current of an inert gas to  $150^\circ$ ,  $\text{SbI}_3$  begins to sublime, and at  $200^\circ$  is given off rapidly; no further change occurs till  $350^\circ$  is reached, when  $\text{SbI}_3$  again sublimates and crystals of  $\text{Sb}_2\text{O}_3$  remain (Cooke, *P. Am. A.* [2] 5, 72). By the action of  $\text{HCl Aq}$ ,  $\text{HNO}_3\text{Aq}$ , or  $\text{H}_2\text{SO}_4\text{Aq}$  on  $\text{SbOI}$ ,  $\text{I}$  is separated.

**Antimony, oxysulphides of.** Various oxysulphides of  $\text{Sb}$ , or more probably mixtures of  $\text{Sb}_2\text{S}_3$  and  $\text{Sb}_2\text{O}_3$ , were formerly used in pharmacy. The compound  $\text{Sb}_2\text{O}_3 \cdot 2\text{Sb}_2\text{S}_3$  occurs native as *antimony blende* (v. H. Rose, *P.* 3, 452). The oxysulphide  $\text{Sb}_2\text{OS}_2$  is obtained as a red-brown powder by boiling  $\text{SbSI}$  (v. ANTIMONY, IODIDES OF) with  $\text{ZnO}$  and  $\text{H}_2\text{O}$  (Schneider, *P.* 110, 147); also by the action of  $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$  on  $\text{SbCl}_3$  in  $\text{HCl Aq}$  (Böttger, *C. C.* 1857, 333). A compound of  $\text{Sb}_2\text{S}_3$  and  $\text{Sb}_2\text{O}_3$  is much used as a brilliant crimson-red pigment; it is probably  $\text{Sb}_2\text{O}_3 \cdot 2\text{Sb}_2\text{S}_3$  (=  $8\text{SbOS}_2$ ), (v. Böttger, *l.c.*; Wagner, *J.* 1858, 235; Kopp, *C. C.* 1859, 945).

**Antimony, phosphides of, v. ANTIMONY, Combinations, No. 8.**

**Antimony, selenides of, v. ANTIMONY, Combinations, No. 6.**

**Antimony, seleno-acid of, v. SELENO-ANTIMONATES, p. 286.**

**Antimony, sulphides of.** Two sulphides are known,  $\text{Sb}_2\text{S}_3$  and  $\text{Sb}_2\text{S}_5$ ; neither has been raised, and therefore mol. w. of neither is

known. Unger (*Ar. Ph.* [2] 147, 193) supposed he had obtained a disulphide,  $\text{Sb}_2\text{S}_4$ , by the action of  $\text{NaOHAq}$  on  $\text{Sb}_2\text{S}_3$ ; but the existence of this  $\text{Sb}_2\text{S}_4$  is very doubtful.  $\text{Sb}_2\text{S}_3$  is a feebly marked salt-forming sulphide, e.g. it dissolves in  $\text{NaOHAq}$  to form  $\text{Na}_2\text{Sb}_2\text{S}_3$  (v. ANTIMONY, THIOACIDS OF).  $\text{Sb}_2\text{S}_3$  is a distinctly salt-forming sulphide; the thio-antimonates (*q. v.*) are well-marked salts. The trisulphide,  $\text{Sb}_2\text{S}_6$ , occurs native; the pentasulphide does not.

**I. ANTIMONIOUS SULPHIDE (*Antimony trisulphide, Mineral Kermes, &c.*)**  $\text{Sb}_2\text{S}_3$  (low red heat). S.G. (*stibnite*) 4.51–4.75; (amorphous) 4.15; (fused, by direct union of  $\text{Sb}$  and  $\text{S}$ ) 4.892 (Ditte, *C. R.* 102, 212). S.I. ( $23^\circ$ – $99^\circ$ ) 0.8433 (Regnault, *A. Ch.* [3] 1, 129; v. also Neumann, *P.* 23, 1). Two forms are known; crystallised (trimeric);  $a:b:c = .985:1:1.0117$  and amorphous.

**Occurrence.**—Native as *Stibnite* or *Antimony glance*, crystallised in trimetric prisms, usually containing  $\text{P}$ ,  $\text{As}$ ,  $\text{Fe}$ , and  $\text{Cu}$ .

**Preparation.**—(a) Crystallised: by gradually heating to redness, in a covered crucible, a mixture of 13 parts of finely powdered  $\text{Sb}$  well mixed with 5 parts pure  $\text{S}$ ; then fusing for some time under a layer of  $\text{NaCl}$ ; cooling, powdering, mixing with a little  $\text{S}$ , and again fusing under  $\text{NaCl}$ . (b) Amorphous: by boiling 4 parts  $\text{KOHAq}$ , S.G. 1.25, and 12 parts  $\text{H}_2\text{O}$ , with one part crude  $\text{Sb}_2\text{S}_3$ , out of contact with air for some time, adding 50 parts boiling  $\text{H}_2\text{O}$ , filtering quickly, and decomposing the solution by dilute  $\text{H}_2\text{SO}_4\text{Aq}$ ; the pp. is collected, boiled with very dilute  $\text{H}_2\text{SO}_4\text{Aq}$ , washed with cold water, digested with aqueous tartaric acid (to remove any  $\text{Sb}_2\text{O}_3$ ), again washed with cold water, pressed, and dried at a low temperature. Cooke (*P. Am. A.* [2] 5, 1) dissolves  $\text{Sb}$  in large excess of  $\text{HNO}_3\text{Aq}$  (S.G. 1.35), keeping the temperature as low as possible, neutralises with  $\text{NaOHAq}$ , dissolves in large excess of  $\text{H}_2\text{C}_2\text{H}_3\text{O}_4\text{Aq}$ , pps. by  $\text{H}_2\text{S}$  in an atmosphere of  $\text{CO}_2$ , collects and washes pp. and dries below  $210^\circ$ . The amorphous sulphide is also produced by melting crystalline  $\text{Sb}_2\text{S}_3$  in a glass tube, and after a time throwing it into a large quantity of cold water (Fuchs, *P.* 31, 578). An impure  $\text{Sb}_2\text{S}_3$ , containing  $\text{Sb}_2\text{O}_3$ , known as *Kermes*, is prepared for commercial purposes by heating crude antimony sulphide with aqueous alkalis or alkaline carbonates.

**Properties.**—(a) Crystalline: grey-black trimetric prisms; melt easily. (b) Amorphous: prepared by pps., is a reddish-brown, loose, powder which marks paper with a brownish streak; prepared by melting and suddenly cooling the crystalline  $\text{Sb}_2\text{S}_3$ , it is a hard greyish mass; melted and cooled slowly it yields the crystalline form; heated to  $210^\circ$ – $220^\circ$  it becomes grey (Cooke, *P. Am. A.* [2] 5, 1). Both forms of  $\text{Sb}_2\text{S}_3$  are insoluble in water, and in  $\text{NH}_4\text{Aq}$ , dissolve in  $\text{KOHAq}$ , in  $\text{HCl Aq}$ , and very slowly in tartaric acid. They may be distilled unchanged in a stream of  $\text{N}$ .

**Reactions.**—The products of the reactions of crystalline and amorphous  $\text{Sb}_2\text{S}_3$  are, in almost every case, the same; the actions usually proceed more rapidly with the amorphous than with the crystalline form. 1. Boiled with water, is partially decomposed to  $\text{Sb}_2\text{O}_3$  and  $\text{H}_2\text{S}$  (De Clermont a. Frommel, *C. R.* 87, 330; Lang, *B.* 18, 2714).—2. Heated in hydrogen,  $\text{Sb}$  is formed.—

**B. Calcined in air,  $\text{Sb}_2\text{O}_3$ , or  $\text{Sb}_2\text{O}_4$ , and  $\text{SO}_2$ , are produced.**—4. Heated in *chlorine*,  $\text{SbCl}_3$  and  $\text{S}_2\text{Cl}_2$  result.—5. Aqueous *hydrochloric acid* forms  $\text{SbCl}_3$  and  $\text{H}_2\text{S}$ ; after a time the action stops, but if the  $\text{H}_2\text{S}$  is removed the whole of the  $\text{Sb}_2\text{S}_3$  is decomposed (*v. Lang*, *B.* 18, 2714; also Berthelot, *C. R.* 102, 22).—6. *Conc. nitric acid* oxidises to nitrate and sulphate of Sb mixed with S.—7. *Aqua regia* forms  $\text{SbCl}_3$ ,  $\text{H}_2\text{SO}_4$ , and S.—8. Dilute solutions of *sulphuric acid* have no action on crystalline  $\text{Sb}_2\text{S}_3$ , but slowly evolve  $\text{H}_2\text{S}$  from amorphous  $\text{Sb}_2\text{S}_3$ ; conc.  $\text{H}_2\text{SO}_4$  evolves  $\text{SO}_2$ , separates S, and forms  $\text{Sb}_2(\text{SO}_4)_3$  (Hensgen, *R. T. C.* 4, 401).—9. Fused with at least 17 parts *nitre*,  $\text{KSbO}_3$  is formed, with Sb sulphate; with less than 17 parts *nitre*,  $\text{Sb}_2\text{O}_3$  is sometimes formed in addition to the other products, or a part of the  $\text{Sb}_2\text{S}_3$  remains unoxidised and combines with K<sub>2</sub>S formed to produce a thio-salt.—10. Melted with excess of *lead oxide*,  $\text{Sb}_2\text{O}_3$ ,  $\text{SO}_2$ , (and Pb), are formed.—11. Melted with *potassium cyanide*, Sb is produced, along with KCNS and a compound of  $\text{Sb}_2\text{S}_3$  and K<sub>2</sub>S.—12. *Iron, zinc*, and many other *metals* reduce  $\text{Sb}_2\text{S}_3$ , when heated with it, forming Sb and a metallic sulphide; metals whose sulphides are basic (*e.g.* K) generally combine with part of the  $\text{Sb}_2\text{S}_3$  to form thio-salts.—13. Many *easily reduced metallic oxides* when heated with  $\text{Sb}_2\text{S}_3$  form  $\text{Sb}_2\text{O}_3$  and  $\text{SO}_2$ .—14. Many *metallic sulphides* combine when heated with  $\text{Sb}_2\text{S}_3$  with production of double compounds; several of these double compounds occur native, *e.g.*  $\text{Sb}_2\text{S}_3 \cdot \text{PbS}$ ;  $\text{Sb}_2\text{S}_3 \cdot \text{Cu}_2\text{S}$ ;  $\text{Sb}_2\text{S}_3 \cdot 3\text{Ag}_2\text{S}$ ; &c.—15. *Alkali sulphides* combine with  $\text{Sb}_2\text{S}_3$  either when heated in the solid state or in solution; the compounds produced are generally known as *livers of antimony*, *q. v.* (*v. also next reaction*); aqueous solutions of these compounds absorb O forming  $\text{Sb}_2\text{O}_3$ , antimonates, and thio-antimonates.—16. *Caustic alkalis* react with  $\text{Sb}_2\text{S}_3$ , when fused together, or when in aqueous solutions, to produce antimonite and thio-antimonite; thus,  $4\text{Sb}_2\text{S}_3 + 4\text{K}_2\text{O} = 6\text{KSbS}_2 + 2\text{KSbO}_2$ ; or  $4\text{Sb}_2\text{S}_3 + 8\text{KOH} = 3(\text{Sb}_2\text{S}_3 \cdot \text{K}_2\text{SAq}) + 6\text{KSbSAq} + \text{Sb}_2\text{O}_3 \cdot \text{K}_2\text{O} + 4\text{H}_2\text{O}$ . Addition of  $\text{HClAq}$  to this solution pps.  $\text{Sb}_2\text{S}_3$ :  $(6\text{KSbSAq} + 2\text{KSbO}_2 \cdot \text{Aq} + 8\text{HClAq} = 4\text{Sb}_2\text{S}_3 + 8\text{KClAq} + 4\text{H}_2\text{O})$ . If, however, much  $\text{Sb}_2\text{S}_3$ , relatively to the amount of KOH, is used, formation of  $\text{KSbSAq}$  proceeds, but the  $\text{KSbO}_2$  being much less soluble pps. along with some oxysulphide and  $\text{Sb}_2\text{O}_3$  which has not combined with KOH (*crocus of antimony*). The solution of  $\text{KSbS}_2$  is acted on by air, giving finally antimonate and thio-antimonate ( $6\text{KSbSAq} + 6\text{O} = 4\text{KSbSAq} + 2\text{KSbO}_2 \cdot \text{Aq}$ ).—17. *Solutions of carbonated alkalis*,  $\text{K}_2\text{CO}_3$  and  $\text{Na}_2\text{CO}_3 \cdot \text{Aq}$ , dissolve  $\text{Sb}_2\text{S}_3$  only on heating; the solutions behave similarly to those obtained by KOHAq and NaOHAq; on boiling in air a pp. of  $\text{KSbO}_2$  ( $\text{Sb}_2\text{O}_3 \cdot \text{K}_2\text{O}$ ) combined with  $\text{Sb}_2\text{S}_3$  is obtained (*Kermes*), and  $\text{KSbS}_2$  remains in solution. When 1 pt.  $\text{Sb}_2\text{S}_3$  is fused at a strong red heat with 3 pts.  $\text{Na}_2\text{CO}_3$ , and  $\text{H}_2\text{O}$  is added, a solution containing antimonate and thio-antimonate is obtained, and Sb is ppd. (probably,  $10\text{NaSbO}_2 \cdot \text{Aq} + 2\text{H}_2\text{O} = 6\text{NaSbO}_2 \cdot \text{Aq} + 4\text{NaOHAq} + 4\text{Sb}$ ). The action of alkalis on  $\text{Sb}_2\text{S}_3$  has been chiefly investigated by Liebig (*A.* 7, 1).

**Combinations.**—With metallic sulphides to

form thio-antimonites (*v. supra*), *q. v.* under ANTIMONY, THIO-ACIDS or.

**Antimonious sulphide; hydrated.** The orange-red pp. obtained by passing  $\text{H}_2\text{S}$  into a solution of  $\text{SbCl}_3$  or  $\text{C}_4\text{H}_9\text{KSbO}_2$ , containing little acid is amorphous hydrated  $\text{Sb}_2\text{S}_3$ , which is fully dehydrated only at  $200^\circ$  (Frobenius; according to Wittstein the pp. contains no chemically combined  $\text{H}_2\text{O}$ , *Fr.* 1870, 262). It behaves towards acids, alkalis, &c. in the same way as amorphous  $\text{Sb}_2\text{S}_3$ . When this pp. is treated with *peroxide of hydrogen*, in presence of  $\text{NH}_4\text{Aq}$ , a portion of it is oxidised to antimonie acid, some of which separates out and some remains in solution as  $\text{NH}_4\text{SbO}_3$  (Raschig, *B.* 18, 2743).

**II. ANTIMONIC SULPHIDE  $\text{Sb}_2\text{S}_5$  (Antimony pentasulphide or persulphide, Golden sulphuret of antimony, &c.).** Mol. w. unknown. Not found native.  $\text{Sb}_2\text{S}_5$  does not directly combine with S; but by heating  $\text{Sb}_2\text{S}_3$ , S, and  $\text{Na}_2\text{CO}_3$  together,  $\text{Na}_3\text{SbS}_5$  is formed, from which  $\text{Sb}_2\text{S}_5$  is obtained by the action of acids.

**Formation.**—1. By the action of  $\text{H}_2\text{S}$  on  $\text{SbCl}_5$  in  $\text{H}_2\text{C}_2\text{H}_3\text{O}_2 \cdot \text{Aq}$ , or on  $\text{Sb}_2\text{O}_5 \cdot x\text{H}_2\text{O}$  suspended in water. — 2. By decomposing solutions of thio-antimonates by dilute acid.

**Preparation.**—10 parts crystallised  $\text{Na}_3\text{SbS}_5 \cdot 9\text{H}_2\text{O}$  (*q. v.* under ANTIMONY, THIO-ACIDS or) are dissolved in 60 parts  $\text{H}_2\text{O}$ ; the solution is poured (with constant stirring) into a cold solution of 3·3 parts pure  $\text{H}_2\text{SO}_4$  in 100 parts  $\text{H}_2\text{O}$ ; the pp. is washed by decantation, then on a filter, with cold water, as quickly as possible; to remove all traces of acid, the pp. is now digested with a cold solution of 1 part  $\text{NaHCO}_3$  in 20 parts  $\text{H}_2\text{O}$  for a few days; it is again washed then pressed, and dried in a dark place at a low temperature.

**Properties.**—A dark-orange powder; insoluble in water; completely soluble in aqueous alkalis; in absence of air, soluble in  $\text{NH}_4\text{Aq}$ , and in aqueous alkali sulphides; soluble in  $\text{Na}_2\text{CO}_3$  or  $\text{K}_2\text{CO}_3 \cdot \text{Aq}$ , not in  $(\text{NH}_4)_2\text{CO}_3 \cdot \text{Aq}$ .

**Reactions.**—1. Heated out of contact with air,  $\text{Sb}_2\text{S}_3$  and S are formed.—2. Decomposed by boiling with *hydrochloric acid*, giving  $\text{SbCl}_3$  and  $\text{H}_2\text{S}$ .—3. *Caustic alkalis* dissolve  $\text{Sb}_2\text{S}_5$ , forming antimonate and thio-antimonate.—4. *Carbon disulphide* dissolves out a little S (about 5 p.c., Rammelsberg, *P.* 52, 193). That this is due to a decomposition of  $\text{Sb}_2\text{S}_5$ , and not to the action of  $\text{CS}_2$  on a mixed S (it has been supposed that the action of  $\text{CS}_2$  proves the non-existence of  $\text{Sb}_2\text{S}_5$ ), is shown by the fact that much less than  $\text{S}_2$  is withdrawn from each  $\text{Sb}_2\text{S}_5$  by  $\text{CS}_2$ , and also by the reactions of the  $\text{Sb}_2\text{S}_5$ , especially the solubility in  $\text{NH}_4\text{Aq}$  in which  $\text{Sb}_2\text{S}_5$  is insoluble, and the insolubility in  $(\text{NH}_4)_2\text{CO}_3 \cdot \text{Aq}$  which dissolves  $\text{Sb}_2\text{S}_3$ .

**Combinations.**—With alkali sulphides to form thio-antimonates, *q. v.* under ANTIMONY, THIO-ACIDS or.

**Antimony, sulpho-acids of, *v.* ANTIMONY, THIO-ACIDS or.**

**Antimony, sulpho- (or thio)- chlorides of.**  $\text{SbSCl}_2 \cdot 7\text{SbCl}_3$ , and  $2\text{SbSCl} \cdot \text{Sb}_2\text{S}_5$ , obtained by action of  $\text{Sb}_2\text{S}_3$  on  $\text{SbCl}_3$ ; and  $\text{SbSCl}$ , obtained by the action of  $\text{H}_2\text{S}$  on  $\text{SbCl}_3$  (*v.* ANTIMONY, CHLORIDES or).

**Antimony, sulpho- (or thio)- iodides of.**  $\text{SbSI}$ ; by action of  $\text{Sb}_2\text{S}_3$  on  $\text{SbI}_3$ , or of  $\text{I}$  on  $\text{Sb}_2\text{S}_3$ , (v. **ANTIMONY, IODIDE OF**).

**Antimony, tellurides of.** v. **ANTIMONY, COMBINATIONS, No. 7.**

**Antimony, thio-acids of.** No thio-acids of Sb are known, but a few thio-antimonites,  $\text{MSbS}$ , and one  $\text{M}_2\text{SbS}_2$ , and a considerable number of well-marked thio-antimonates,  $\text{M}_2\text{SbS}_4$ , have been prepared. The thio-antimonites may be regarded as derived from the hypothetical acid  $\text{HSbS}_2$  ( $=\text{SbS.SH}$ ); they correspond in composition with the antimonites  $\text{MSbO}_2$ , and with the meta-thio-arsenites  $\text{MA}_2\text{S}_2$ . The thio-antimonates may be regarded as derived from the hypothetical acid  $\text{H}_2\text{SbS}_4$  ( $=\text{SbS}(\text{SH})_3$ ); no corresponding antimonates are known ( $\text{MSbO}_3$  and  $\text{M}_2\text{Sb}_2\text{O}_7$  represent the antimonates); the thio-arsenites are represented by three series, one of which (the ortho-series) corresponds with the thio-antimonates.

**THIO-ANTIMONITES.** A very few of these salts have been prepared. Addition of absolute alcohol to a solution of  $\text{Sb}_2\text{S}_3$  in  $\text{NaOHAq}$  pps. amorphous  $\text{NaSbS}_2$ , soluble in water. By heating to  $30^\circ$  equivalents of  $\text{Sb}_2\text{S}_3$  and  $\text{NaOH}$  (in conc. solution) copper-coloured  $2\text{NaSbS}_2 \cdot \text{H}_2\text{O}$  is formed (Unger, *J.* 1871. 325). The silver salt  $\text{Ag}_2\text{SbS}_2$  is said to be obtained as a grey mass, reddish when powdered, by heating  $\text{Ag}_2\text{SbS}_2$  out of contact with air (Rammelsberg, *P.* 52, 193). Several minerals may be regarded as thio-antimonites, e.g.  $\text{PbS.Sb}_2\text{S}_3$ ;  $\text{Ag}_2\text{S.Sb}_2\text{S}_3$ ;  $\text{Cu}_2\text{S.Sb}_2\text{S}_3$ ;  $\text{FeS.Sb}_2\text{S}_3$ , &c.

**THIO-ANTIMONATES**  $\text{M}_2\text{SbS}_4$ . Investigated chiefly by Rammelsberg (*P.* 52, 193). Some of these salts are obtained by the action of alkali sulphides on  $\text{Sb}_2\text{S}_3$ ; but they are better obtained by acting on  $\text{Sb}_2\text{S}_3$  with aqueous solutions of alkali sulphides in presence of sulphur, or with aqueous solutions of alkali polysulphides. They are also obtained by fusing  $\text{Sb}_2\text{S}_3$  with alkali sulphides (or with sulphates and carbon) and sulphur. The decomposition, in air, of alkaline livers of antimony also often yields thio-antimonates (v. **ANTIMONIOUS SULPHIDE, Reactions, No. 15 and 16**). The thio-antimonates of the alkali metals are soluble in water, many of the others are insoluble and are obtained from the alkali salts by ordinary double decompositions, the metallic salt solution being added in quantity less than sufficient to decompose the whole of the alkali thio-antimonate. Solutions of thio-antimonates are easily decomposed by acids, even by the  $\text{CO}_2$  of the air, with pps. of  $\text{Sb}_2\text{S}_3$ , and, when exposed to air, of alkali thio-sulphate. The alkali thio-antimonates are not decomposed by heating out of contact with air; the salts of the heavy metals lose  $\text{S}$ , and give thio-antimonites. The more important thio-antimonates are those of potassium and sodium.

**Potassium thio-antimonate.**  $2\text{K}_2\text{SbS}_4 \cdot 9\text{H}_2\text{O}$ ; slightly yellow deliquescent crystals; prepared by boiling, for several hours, 1 part  $\text{S}$ , 6 parts  $\text{K}_2\text{CO}_3$ , 3 parts  $\text{CaO}$ , and 20 parts  $\text{H}_2\text{O}$ , with 11 parts  $\text{Sb}_2\text{S}_3$ , filtering, and cooling out of contact with air. A salt  $\text{K}_2\text{SbS}_4 \cdot \text{KSbO}_3 \cdot 5\text{H}_2\text{O}$  is obtained, in long white needles, by adding cold conc.  $\text{KOH}$  to  $\text{Sb}_2\text{S}_3$ , filtering from  $2\text{KH}(\text{SbO}_3) \cdot 5\text{H}_2\text{O}$  which separates out, and evaporating (v. Schiff, *A.* 114, 202).

**Sodium thio-antimonate**  $\text{Na}_2\text{SbS}_4 \cdot 9\text{H}_2\text{O}$

(known as *Schlippe's salt*). Prepared by fusing together 16 parts dry  $\text{Na}_2\text{SO}_4$ , 18 parts  $\text{Sb}_2\text{S}_3$ , and 4-5 parts wood charcoal, dissolving in water, boiling with 2½ parts sulphur, filtering and evaporating; the crystals are washed with very dilute  $\text{NaOHAq}$  and then with water, and dried quickly at a low temperature. The salt may also be prepared by boiling  $\text{Na}_2\text{CO}_3\text{Aq}$  with  $\text{CaO}$ ,  $\text{Sb}_2\text{S}_3$ , and  $\text{S}$ . Sodium thioantimonate forms large yellowish monometric tetrahedra; it dissolves in 2.9 parts  $\text{H}_2\text{O}$  at  $15^\circ$ , the solution has an alkaline reaction. The crystals are best kept in contact with their mother liquor to which a little  $\text{NaOHAq}$  is added; they decompose in air, giving  $\text{Sb}_2\text{S}_3$ ,  $\text{Sb}_2\text{S}_5$ ,  $\text{Na}_2\text{S}$ ,  $\text{Na}_2\text{CO}_3$ , and  $\text{Na}_2\text{S}_2\text{O}_3$ . When the mother liquor from Schlippe's salt is evaporated, crystals of a double salt  $\text{Na}_2\text{SbS}_4 \cdot \text{Na}_2\text{S}_2\text{O}_3 \cdot 20\text{H}_2\text{O}$  are obtained. Solution of tartar emetic is decomposed by  $\text{Na}_2\text{SbS}_4\text{Aq}$  thus:  $6\text{C}_2\text{H}_3\text{KSO}_4\text{Aq} + 2\text{Na}_2\text{SbS}_4\text{Aq} =$

The other thio-antimonates are generally obtained from the sodium salt: the best-marked are  $\text{Ba}_2(\text{SbS}_4)_2 \cdot 6\text{H}_2\text{O}$ ;  $\text{Cu}_2(\text{SbS}_4)_2$ ;  $\text{Pb}_2(\text{SbS}_4)_2$ ;  $\text{Hg}_2(\text{SbS}_4)_2$ ;  $\text{Ag}_2\text{SbS}_4$ ; a few others are known (e.g. of  $\text{Cd}$ ,  $\text{Co}$ ,  $\text{Mn}$ ,  $\text{Ni}$ ,  $\text{V}$ ,  $\text{Zn}$ ) but they are very easily decomposed, and not many have been obtained in definite forms. M. M. P. M.

**Tri-methyl-stibine**  $\text{SbMe}_3$ . Mol. w. 167. ( $81^\circ$ ). S.G.  $1.5$ ; 1.523.

**Preparation.**—An alloy of antimony (4 pts.) and sodium (1 pt.) is mixed with sand and  $\text{MeI}$  and distilled.  $\text{MeI}$  and  $\text{SbMe}_3$  pass over but unite in the receiver to form  $\text{SbMe}_3\text{I}$ , which when distilled with an alloy of antimony and potassium in a current of  $\text{CO}_2$  gives  $\text{SbMe}_3$  (Landolt).

**Properties.**—Liquid, smelling of onions, sl. sol. water; may take fire in air. Takes fire in chlorine. Reduces salts of silver and mercury.

**Salts.**—Unites directly with non-metals.— $\text{SbMe}_2\text{Cl}$ : hexagonal crystals, sl. soluble in water. Formed also from  $\text{SbCl}_3$  and  $\text{HgMe}_2$ .— $\text{SbMe}_2\text{Cl.SbMe}_2\text{O}$ : octahedra, sol. water.— $\text{SbMe}_2\text{Br}$ .— $\text{SbMe}_2\text{Br.SbMe}_2\text{O}$ : octahedra, sol. water.— $\text{SbMe}_2\text{I}_2$ : formed by heating  $\text{Sb}$  with  $\text{MeI}$  at  $140^\circ$ .— $\text{SbMe}_2\text{I}_2\text{SbMe}_2\text{O}$ : octahedra.— $\text{SbMe}_2\text{S}$ : scales.— $\text{SbMe}_2(\text{NO}_3)_2$ .— $\text{SbMe}_2\text{SO}_4$ .

**Tetra-methyl-stibonium salts.**  $\text{SbMe}_4\text{I}$ . *S.* 80 at  $23^\circ$ . From  $\text{SbMe}_3$  and  $\text{MeI}$ : six-sided plates. When distilled the vapour ( $\text{SbMe}_4 + \text{MeI}$ ) takes fire in air.— $\text{SbMe}_4\text{OH}$ : from moist  $\text{Ag}_2\text{O}$  and the above. Deliquescent alkaline crystals: absorbs  $\text{CO}_2$  from air, and expels  $\text{NH}_3$  from its salts. Pps. baryta from  $\text{BaI}_2$ , also the hydrates of  $\text{Pb}$ ,  $\text{Ca}$ ,  $\text{Cu}$ ,  $\text{Hg}$ ,  $\text{Ag}$ , and  $\text{Zn}$ ; only the last pp. is soluble in excess.— $\text{SbMe}_4\text{Cl}$ : very soluble hexagonal plates; v. sl. sol. ether.— $(\text{SbMe}_4\text{Cl})_2\text{PtCl}_4$ : difficultly soluble orange powder; sl. sol. water, insol. alcohol and ether.— $\text{SbMe}_4\text{Br}$ .— $(\text{SbMe}_4)_2\text{S}$ :

soluble green powder; oxidises rapidly. —  $\text{SbMe}_2\text{NO}_3$ , [150°]: crystals, v. sol. water, not decomposed by boiling concentrated  $\text{H}_2\text{SO}_4$ . —  $\text{SbMe}_2\text{SO}_3\text{H}$ : soluble plates. —  $(\text{SbMe}_2)_2\text{SO}_3$ , 6aq.

**Di-methyl-stibine sulphides**  $(\text{SbMe}_2)_2\text{S}_2$ , (c. 100°) and  $(\text{SbMe}_2)_2\text{S}$  are formed by passing  $\text{H}_2\text{S}$  into an ethereal solution of  $\text{SbMe}_3$  that has been oxidised by exposure to air.

**Antimony penta-methide**  $\text{SbMe}_5$ , (c. 98°). Formed together with antimony tetra-methide,  $(\text{SbMe}_4)_2$ , (c. 90°), by distilling trimethyl stibine iodide with  $\text{ZnMe}_2$ . Both are oils which do not fume in air.

**Methyl-tri-ethyl-stibonium salts**  $\text{SbMeEt}_3\text{I}$ . S. 50 at 20°. From  $\text{SbEt}_3$  and  $\text{MeI}$ . Glassy prisms, sol. alcohol, insol. ether; the solutions are levorotatory.  $\text{HgCl}_2$  gives a precipitate of  $\text{SbEt}_3\text{MeI}$ ;  $\text{HgI}_2$ . —  $\text{SbMeEt}_3\text{OH}$ ; from moist  $\text{Ag}_2\text{O}$  and the iodide, or from the sulphate and baryta. Pps. metallic salts, the hydrates of zinc and aluminium dissolving in excess. —  $\text{SbMeEt}_3\text{Cl}$ : small needles. —  $\text{SbMeEt}_3\text{HgI}_2$ . —  $(\text{SbMeEt}_3)_2\text{CO}_3$ : amorphous. —  $(\text{SbMeEt}_3)_2\text{SO}_4$ : [100°], deliquescent, shining, bitter crystals. —  $(\text{SbMeEt}_3)_2\text{C}_2\text{O}_4$ : glassy needles, m. sol. water. —  $\text{SbMeEt}_3\text{C}_2\text{O}_4\text{H}$ : needles, v. sol. water. — The acetate, formate, and butyrate are crystalline.

**Tri-ethyl-stibine**  $\text{SbEt}_3$ , Mol. w. 209. (159°). S.G.  $^{25}$ : 1.324. V.D. 7.44 (calc. 7.18).

**Formation**.—1. From  $\text{SbCl}_3$  and  $\text{ZnEt}_2$ . — 2. From  $\text{EtI}$  and a mixture of sand with an alloy of Sb and potassium. — 3. From  $\text{SbCl}_3$  and  $\text{HgEt}_2$ . — 4. By distilling  $\text{SbEt}_3\text{I}$  with Zn.

**Properties**.—Oil, smelling of garlic, v. sol. alcohol and ether. Takes fire in air; hence it should be kept under water. Decomposes fuming hydrochloric acid with evolution of hydrogen:  $\text{SbEt}_3 + 2\text{HCl} = \text{SbEt}_2\text{Cl} + \text{H}_2$ . When slowly oxidised it forms  $\text{SbEt}_2\text{O}$  and  $\text{SbEt}_3(\text{SbO})_2$ . Combines directly with S, Se, I, Br, and Cl. Dilute  $\text{HNO}_3$  dissolves it, giving off NO and forming  $\text{SbEt}_3(\text{NO}_3)_2$ . In all these reactions tri-ethyl-stibine behaves like a metal. An alcoholic solution of  $\text{SbEt}_3$  shaken with  $\text{HgO}$  liberates Hg while  $\text{SbEt}_2\text{O}$  remains in the solution.

**Tri-ethyl-stibine-oxide**  $\text{SbEt}_2\text{O}$ .

**Formation**.—1. From  $\text{SbEt}_3\text{I}_2$  and  $\text{Ag}_2\text{O}$ . — 2. From  $\text{SbEt}_3\text{SO}_4$  and baryta. — 3. By slow oxidation of an alcoholic or ethereal solution of  $\text{SbEt}_3$ ;  $\text{SbEt}_3(\text{SbO})_2$  is formed at the same time, but this differs from  $\text{SbEt}_2\text{O}$  in being insol. ether. — 4. By shaking alcoholic  $\text{SbEt}_3$  with  $\text{HgO}$ .

**Properties**.—A syrup, v. sol. water and alcohol, m. sol. ether; combines with acids and precipitates metals as hydrates from solutions of their salts. If its aqueous solution is free from  $\text{SbEt}_3(\text{SbO})_2$ , no pp. is produced by  $\text{H}_2\text{S}$ ; otherwise a pp. of  $\text{SbEt}_3(\text{SbS})_2$  is formed. Potassium converts it into  $\text{SbEt}_4$ .

**Tri-ethyl-stibine salts**.

**Chloride**.— $\text{SbEt}_3\text{Cl}$ . S.G.  $^{12}$ : 1.540. Oil, soluble in alcohol. Ppd. by adding  $\text{HCl}$  to an aqueous solution of the iodide or sulphate. Conc.  $\text{H}_2\text{SO}_4$  decomposes it, giving off  $\text{HCl}$ .

**Oxy-chloride**.— $\text{SbEt}_3\text{Cl}_2\text{SbEt}_2\text{O}$ . From the oxy-iodide and  $\text{HgCl}_2$ . Deliquescent solid.

**Bromide**.— $\text{SbEt}_3\text{Br}$ . S.G.  $^{12}$ : 1.953. Solidifies at  $-10^\circ$ . Insol. water, sol. alcohol and ether. Behaves like a metallic bromide.

**Iodide**.— $\text{SbEt}_3\text{I}$ . [71°]. Formed by heating

Sb with  $\text{EtI}$  at 140°; or by adding iodine to an alcoholic solution of  $\text{SbEt}_3$  at  $-15^\circ$ . Needles (from ether). Unlike the chloride, it is soluble in water. Potassium removes the iodine thus:  $\text{SbEt}_3\text{I} + \text{K} = 2\text{KI} + \text{SbEt}_3$ .

**Oxy-iodide**.— $\text{SbEt}_3\text{I}_2\text{SbEt}_2\text{O}$ . Formed by treating the iodide with  $\text{NIH}_3$ ; or by mixing the iodide with the oxide  $\text{SbEt}_2\text{O}$ .

**Sulphide**.— $\text{SbEt}_3\text{S}$ . From the oxide and  $\text{H}_2\text{S}$  or from  $\text{SbEt}_3$  and S. Soluble in water and alcohol. Its aqueous solutions pp. metals as sulphides from their salts.

**Nitrate**.— $\text{SbEt}_3(\text{NO}_3)_2$ . [63°]. Formed by dissolving  $\text{SbEt}_3$ , or its oxide, in dilute  $\text{HNO}_3$ . Rhombohedra, soluble in water.

**Oxy-nitrate**.— $\text{SbEt}_3\text{O}_2\text{HNO}_3$ . From the oxy-iodide and  $\text{AgNO}_3$ .

**Sulphate**.— $\text{SbEt}_3\text{SO}_4$ , [100°]. From the sulphide and  $\text{CuSO}_4$ . Small prisms, sol. water and alcohol.

**Oxy-sulphate**.— $(\text{SbEt}_2\text{O})_2\text{H}_2\text{SO}_4$ . From the oxy-iodide and  $\text{Ag}_2\text{SO}_4$ . Gummy mass.

**Tetra-ethyl-stibonium salts**.

**Iodide**.— $\text{SbEt}_4\text{I}$ , 1 $\frac{1}{2}$ aq (and 3aq). S. (anhydrous): 19 at 20°. From  $\text{SbEt}_3$ , water, and  $\text{EtI}$  at 100°. Hexagonal prisms, sol. alcohol and ether. —  $\text{SbEt}_4\text{I} \frac{1}{2}\text{HgI}_2$ . —  $\text{SbEt}_4\text{I} \frac{1}{2}\text{HgI}_2$ .

**Hydrate**.— $\text{SbEt}_4\text{OH}$ . From moist  $\text{Ag}_2\text{O}$  and the above. Alkaline syrup. Pps. metallic hydrates from salts: stannic oxide and alumina dissolve in excess. Expels  $\text{NIH}_3$  from its salts.

**Chloride**.— $\text{SbEt}_4\text{Cl}$ . Hygroscopic needles. Forms compounds with  $\text{HgCl}_2$  and with  $\text{PtCl}_4$ .

**Bromide**.— $\text{SbEt}_4\text{Br}$ , 1 $\frac{1}{2}$ aq: needles.

**Periodide**.— $\text{SbEt}_4\text{I}_2$ .

**Nitrate**.— $\text{SbEt}_4\text{NO}_3$ : deliquescent needles.

**Sulphate**.— $(\text{SbEt}_4)_2\text{SO}_4$ : deliquescent mass.

**Oxalate**.— $(\text{SbEt}_4)_2\text{C}_2\text{O}_4$ .

**Antimony penta-ethide**  $\text{SbEt}_5$  (?). (c. 165°). From  $\text{SbEt}_3\text{I}_2$  and  $\text{ZnEt}_2$ .

**Tri-isoamyl-stibine**  $\text{Sb}(\text{C}_4\text{H}_9)_3$ . From an alloy of Sb with K by  $\text{C}_4\text{H}_9\text{I}$ . Fuming liquid, does not take fire in air.

**Oxide**.— $\text{Sb}(\text{C}_4\text{H}_9)_2\text{O}$ : insoluble resin, soluble in alcohol.

**Salts**.— $\text{Sb}(\text{C}_4\text{H}_9)_2\text{Cl}$ : oil, heavier than water, soluble in alcohol, ppd. by water. —  $\text{Sb}(\text{C}_4\text{H}_9)_2\text{Br}$ : oil. —  $\text{Sb}(\text{C}_4\text{H}_9)_2\text{I}$ : oil. —  $\text{Sb}(\text{C}_4\text{H}_9)_2(\text{NO}_3)_2$ : [20°] slender crystals, insoluble in water, soluble in alcohol. —  $\text{Sb}(\text{C}_4\text{H}_9)_2\text{SO}_4$ : oil.

**Antimony di-isoamyl**  $\text{Sb}_2(\text{C}_4\text{H}_9)_4$  (?). Formed by distilling  $\text{Sb}(\text{C}_4\text{H}_9)_3$ . A heavy oil, soluble in alcohol. Does not fume in air, but explodes in oxygen. Its salts are amorphous.

**Tri-phenyl-stibine**  $\text{SbPh}_3$ . [48°] (above 360°). S.G.  $^{12}$  1.500. From  $\text{SbCl}_3$  (1 pt.), chloro-benzene (1 pt.) and Na; benzene being used as diluent. Small quantities of  $\text{SbPh}_2\text{Cl}_2$  and  $\text{SbPhCl}_2$  are also formed. The benzene deposits crystalline  $\text{SbPh}_3$ ; this is warmed with alcohol containing  $\text{HCl}$ , which dissolves  $\text{SbPh}_2\text{Cl}_2$ , and the residual  $\text{SbPh}_3$  is converted into  $\text{SbPh}_2\text{Cl}_2$  by chlorine. The latter is reduced by alcoholic ammonia and hydrogen sulphide:  $\text{SbPh}_2\text{Cl}_2 + \text{H}_2\text{S} = \text{SbPh}_3 + 2\text{HCl} + \text{S}$ .

**Properties**.—Colourless triclinic tables  $a:b:c = 6.97:1:8.89$ .  $\alpha = 100^\circ 38'$ .  $\beta = 103^\circ 37'$ .  $\gamma = 75^\circ 25'$ ; sl. sol. alcohol, v. e. sol. ether, benzene, glacial  $\text{HOAc}$ ,  $\text{CS}_2$ , chloroform, and petroleum; insol. water and aqueous  $\text{HCl}$ . It does not decompose  $\text{HCl}$ ; but it combines directly with

halogens; it reduces cupric, to cuprous, chloride. With mercuric chloride it reacts as follows:

Fuming  $\text{HNO}_3$  forms  $\text{SbPh}_3(\text{NO}_3)_2$ .

**Salts.**— $\text{SbPh}_3\text{Cl}_2$  [143°]: long thin needles; not affected by water; insol. light petroleum, *sl.* sol. ether and alcohol, *v. sol.* benzene and  $\text{CS}_2$ .— $\text{SbPh}_3\text{Br}_2$  [216°].— $\text{SbPh}_3\text{I}_2$  [153°]: white tables.— $\text{SbPh}_3(\text{OH})_2$  [212°]. From the bromide and alcoholic  $\text{KOH}$ . Amorphous powder, *sol.* glacial  $\text{HOAc}$  and reppd. unaltered by water. Insol. ether, *v. c. sol.* alcohol. Converted by  $\text{HCl}$ ,  $\text{HBr}$ , or  $\text{HI}$  into haloid salt.— $\text{SbPh}_3(\text{NO}_3)_2$  [156°]. Insol. water, *sol.* alcohol.

**Antimony di-phenyl chloride**  $\text{SbPh}_2\text{Cl}_2$  aq. [180°]. Obtained as a by-product in preparing  $\text{SbPh}_3$ . Needles, insol. water, *sol.* hot dilute  $\text{HCl}$ , *v. c. sol.* alcohol. Alcoholic  $\text{NH}_3$  converts it into  $\text{Ph}_2\text{SbO}(\text{OH})$ , a white powder, insol. water, ammonia, alcohol, ether, or  $\text{Na}_2\text{CO}_3$  aq, but *sol.*  $\text{NaOH}$  aq and glacial  $\text{HOAc}$ .

**ANTIPIRYNE** *v. Oxy-di-METHYL-QUINIZINE*.

**APHRODÆSIN**. A substance contained in the cotyledons of the horse-chestnut (*v. Escnic Acid*).

**APIIN**. When common parsley (*Apium petroselinum*) is extracted with boiling water the filtrate gelatinises on cooling. The jelly is dried at 100° and extracted with alcohol, and the alcohol poured into water. The operation of dissolving in alcohol and ppg. with water is repeated several times, and the apiin finally crystallised from alcohol, with stirring. Apiin also occurs in parsley seed; if this is boiled with water, apiol distils over, while apiin separates out from the residue.

**Properties.**—Needles; *sl.* sol. cold water, *v. sol.* hot water, separating again as a jelly; *v. sol.* alcohol; insol. ether. Its solution in boiling water gives a blood-red colour with  $\text{FeSO}_4$ . Gives picric acid with  $\text{HNO}_3$ ; and phloroglucin by potash fusion.

**Apigenin**  $\text{C}_{15}\text{H}_{10}\text{O}_6$ . Boiling dilute  $\text{H}_2\text{SO}_4$  splits up apiin into apigenin and glucose:

Crystallises in plates (from alcohol). It sublimes near 294°. *Sl.* sol. hot water, *v. sol.* alcohol, insol. ether. Potash fusion gives phloroglucin, protocatechuic acid, *p*-oxybenzoic acid, and oxalic acid.

**References.**—Rump, Buchner's *Repert. f. Pharm.* 6, 6; Braconnot, *A. Ch.* [3] 9, 250; *v.* Planta n. Wallace, *A.* 74, 262; Lindenborn, *B.* 9, 1123; *v.* Gerichten, *B.* 9, 1121; Whitney, *Ph.* [3] 10, 585.

**APIOL**  $\text{C}_{15}\text{H}_{14}\text{O}_4$ . [30°]. (*c.* 300°). Extracted by alcohol from parsley seeds (*v.* Gerichten, *B.* 9, 1477). Needles; insol. water. Alcoholic  $\text{KOH}$  converts it into two crystalline bodies. [54°] and [114°]. "The essential oil obtained by distilling parsley seeds with water contains apiol but consists chiefly of a terpene, (160°–164°), S.G. 1.865, [ $\alpha$ ] –30.8°. It has a strong smell of parsley. A small quantity of a hydrochloride, [116°], can be got from it.

Joret, *J. Ph.* [8] 23, 212; and the references under Apiin.

**APŌ-** Compounds beginning with this prefix are described under the words to which it is prefixed.

**APOCYNIN**. The root of *Apocynum Canbium* contains amorphous resinous apocynin, *sol.* alcohol and ether, *v. sl.* sol. water, and a glucoside, apocynin (Schmiedeberg, *Ph.* [3] 13, 942).

**APOPHYLENIC ACID**. The methylohydroxide of cinchomeronic acid; *v.* PYRIMINIC DI-CARBOXYLIC ACID.

**APPLES**. The artificial essence of apples contains iso-amyl iso-valerate dissolved in rectified spirit (Hofmann, *A.* 81, 87).

**APRICOTS**. The artificial essence of apricots contains isoamyl butyrate and isoamyl alcohol.

**AQUA REGIA** *v.* CHLORHYDRIC ACID.

**AQUA VITE**. Alcohol.

**ARABIC ACID** (Arabin)  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ;  $\pi\text{C}_8\text{H}_{16}\text{O}_4$  (Neubauer, *J. pr.* 62, 193; 71, 255;  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$  (Scheibler, *B.* 6, 612);  $\text{C}_{10}\text{H}_{18}\text{O}_{11}$  (O'Sullivan, *C. J.* 45, 41).

**Occurrence.**—It is a constituent of probably all *Levorotatory* gums, and has been isolated from Levantine, Senari, East Indian, Senegal, and Turkey, gum; these gums contain also, as a rule, other acids different from, but closely allied to arabic acid (O'Sullivan). It exists in sugar-beet (Scheibler), and in the extract of yeast obtained by boiling water (Schützenberger, *Bl.* [2] 21, 204; *C. R.* 78, 493). The beet gum is probably related to arabic acid, but there is no evidence that the yeast-extract body belongs to the arabin group. Many gum-like constituents of seeds and roots are referred to as gums, but the great bulk of them obviously hold no relation to arabic acid. It is found in certain animals (Städeler, *A. Ph.* 111, 26).

**Formation.**—It is a product of the action of sulphuric acid on algae-mucilage (Brown, *Ed. Ph. I.* 26, 409); on quince, linseed, and flea-wort mucilages, cellulose being at the same time produced (Kirchner n. Tollens, *A.* 175, 205); and on metagummic acid (Frémy, *C. R.* 50, 125). Cellulose is transformed into gum in plants (Mercadante, *G.* 5, 408). In none of these cases have we any information as to the character of the gum produced.

**Preparation.**—The *Levorotatory* gums are principally potassium, magnesium, and calcium salts of arabic or allied acids; they contain from 12 to 18 p.c. water, and yield 2.7 to 3.0 p.c. ash consisting almost wholly of carbonates of these metals. Any one of these gums is dissolved in the least possible quantity of water, the solution is allowed to stand, and, when clear, decanted from any insoluble matter. To the clear liquid twice or thrice as much  $\text{HCl}$  as is sufficient to convert the bases into chlorides is added, and the gum-acid or acids are precipitated by a moderate excess of alcohol. If the gum contains only arabic acid, the whole pp. can be purified as is described below when dealing with one of the fractions; but if, as is very frequently the case, other allied acids are also present, it is necessary to have recourse to fractional precipitation to isolate the arabic acid. It is found in the fractions least soluble in dilute alcohol, and may be obtained as follows:—The

curdy pp., produced by excess of alcohol in presence of HCl, is well washed with spirit, and then pressed as free from it as possible. It is redissolved in warm water, care being taken to avoid heating for any length of time, because even the small quantity of HCl retained by the pp. has a tendency on heating even for a short time to decompose the arabic acid, as will be described below. The solution is cooled, and alcohol gradually added with continual stirring. In this way, the liquid can be made milky without the formation of a pp.; from this 'milk' the acid or acids can be precipitated in successive fractions by the addition of HCl in carefully graduated quantities. If 4 or 5 fractions are obtained, one or more of them is arabic acid. Each fraction is freed from ash by repeated precipitation from aqueous solution with alcohol in the least possible excess in presence of HCl, and from HCl by repeated precipitation from concentrated solution by the rapid addition of strong alcohol, whereby the production of a 'milk' is obviated. The fractions thus purified are treated with alcohol (S.G. .81) to render them friable, rubbed down to a powder, filtered out, pressed, and dried over sulphuric acid. Thus prepared they are white, friable bodies, easily soluble in water. If in this state they are exposed for any length of time to a temperature of 100°, they are converted into the meta modifications (meta acids) which are insoluble in water and only swell up to jelly-like masses when treated with it. If, however, they are previously dried *in a vacuum* over sulphuric acid until the weight becomes constant, they can then be dried at 100° without becoming insoluble. The fraction or fractions which are found to have an optical activity,  $[\alpha]_D = -26^\circ$  to  $-28^\circ$ , and which, when again divided, yield fractions each of which has the same activity, consist of arabic acid.

**Properties.**—Arabic acid, when slowly dried out of syrupy solutions, on glass plates, is a brittle, transparent, colourless, glassy body, soluble in water. During the drying process, especially if a little mineral acid is present, the acid is frequently converted into the meta modification. Solutions of the body are strongly acid to litmus paper, and have a sharp acid taste; they completely neutralise solutions of the alkalis and alkaline earths, and decompose carbonates. The salts of the alkaline earths are precipitated out of solution by alcohol; those of the alkalis are not precipitated under the same conditions, but yield peculiar milky or opalescent solutions from which arabic acid, with some of the alkaline salt, is precipitated on the addition of stronger acids. BaSO<sub>4</sub>, PbS, and other sulphides, and some hydrates precipitated in solutions of arabic acid, cannot be filtered out, but pass, in greater part, through the filter. Fine animal charcoal is carried through in the same way (C.O.S.). Gum arabic prevents the precipitation of the alkaloids by phosphomolybdic acid, potassium-mercury iodide, and tannin (Lefort a. Thibault, *J. Ph.* [5] 6, 169). These are properties common to all the gum acids. The defining characters of arabic acid are its optical activity, viz.  $[\alpha]_D = -26^\circ$  to  $-28^\circ$ , for solutions containing 5 to 6 grams dry substance in 100 c.c., and the composition of its neutral

barium and calcium salts; in the dry state, the former contains 6.0 p.c. BaO and the latter 2.28 p.c. of CaO (O.S.). Solid gum roasted with oxalic acid yields metagummic acid (Frémy), this is dissolved by solutions of the alkalis and alkaline earths with the reproduction of arabic acid (v. Rhem. *D. P. J.* 216, 539). Gum arabic and tragacanth are rendered insoluble by potassium bichromate and light (Eder. *J. pr.* 19, 299). Gum, even in small quantities, injected into the blood diminishes the elimination of urine, large doses completely stop the secretion, with a marked increase of blood pressure (Richey a. Montard-Martin, *C. R.* 90, 88).

**Reactions.**—1. Heated with moderately strong nitric acid, arabic acid yields mucic (v. Kiliani, *B.* 15, 31), saccharic, oxalic, and tartaric (Liebig) acids; with fuming nitric acid it yields substitution products.—2. Gum heated in sealed tubes with bromine yields a colourless or yellowish liquid, probably C<sub>12</sub>H<sub>20</sub>O<sub>10</sub>Br, which, when treated with silver oxide, lead oxide, or caustic soda, is converted into isodiglycolethylene acid, C<sub>12</sub>H<sub>20</sub>O<sub>12</sub> (Barth a. Illasiwetz, *A. Ch. Pharm.* 122, 96). It is possible some of the decomposition products of arabic acid would yield the same results. 3. Gum arabic or arabin when heated to 150° with 2 parts acetic anhydride yields tetracetyl-di-arabin (?) C<sub>12</sub>H<sub>14</sub>(C<sub>2</sub>H<sub>3</sub>O)<sub>4</sub>O<sub>10</sub>; and, when heated to 180° with 6 to 8 parts of the anhydride, a body having the composition C<sub>12</sub>H<sub>13</sub>(C<sub>2</sub>H<sub>3</sub>O)<sub>4</sub>O<sub>10</sub>; these acetyl derivatives are white amorphous powders (Schützenberger a. Naudin, *A. Ch.* [4] 21, 235). These bodies are certainly not derived from arabic acid as a whole, but from some one of its decomposition products (C.O.S.).—4. *Pepsin*, in dilute HCl solution, acts on dextrorotatory gum acid, arabinose being amongst the products; *pancreatin* has no action (Fudakowski, *B.* 11, 1072). 5. (a) Gum arabic left for some time in contact with sulphuric acid is converted into dextrin (!) and, on boiling, yields a sugar probably identical with galactose (Berthelot, *C. O.* 21, 219). (b) Strong sulphuric acid converts a strong solution of gum in a few hours into metagummic acid; but gum arabic freed from lime by oxalic acid is not transformed in the same way (Frémy). (c) Pulverised gum arabic, triturated with strong sulphuric acid, yields sulphogummic acid and a peculiar gum resembling that produced from linen by the action of sulphuric acid (Braconnot) and not capable of fermenting with yeast (Guérin-Varry). (d) Arabic acid, digested with dilute sulphuric acid, yields a crystallisable sugar, a non-crystallisable one, and an acid the barium salt of which is insoluble in alcohol: gums from different sources yield these bodies in various proportions, some varieties yielding scarcely any of the crystallisable sugar (Scheibler, *B.* 6, 612). (e) A solution containing 30 grams arabic acid (pure), 100 c.c. water, and 2 grams sulphuric acid, yields, on digestion at 100° for 15 minutes, at least two sugars and a new acid the Ba salt of which is insoluble in alcohol: the following equations represent the change:—

Continued digestion produces changes that may be represented as follows:—

III. IV. V. VI. VII. and VIII.

$\beta$ -arabinosio acid,  $\beta$ - $\gamma$ -arabinose.

On further digestion we get:

$\alpha$ -arabinosio acid  $\delta$ -arabinose (?)

$\alpha$ -arabinosio acid,  $\delta$ -arabinose (?)

$\alpha$ -arabinosio acid  $\delta$ -arabinose (?)

This last acid is very stable, resisting the action of a boiling 3 to 4 p.c. solution of sulphuric acid for a considerable time (O'Sullivan, *C. J.* 45, 41).  $\alpha$ -arabinose is not yet fully described;  $\beta$ -arabinose<sup>1</sup> is Scheibler's arabinose,  $\gamma$ -arabinose is probably identical with galactose, and the remaining sugar or sugars are imperfectly described. These reactions convey some idea of the constitution of the gums of the arabin group, i.e. of those which are salts of a gum-acid with alkaline or alkaline-earthly bases, and enable us to understand some of the differences observed in their properties. Those bodies vary considerably in optical activity; this is due (a) to the varying proportions of different closely related acids they contain. O'Sullivan found the acid of some samples of gum arabic to consist almost wholly of arabic acid, whilst others contained also  $\alpha$ -arabinosio acid,  $[\alpha]_D = -36^\circ$ , and an acid ( $C_{20}H_{128}O_{227}$ ),  $[\alpha]_D = -23^\circ$ , with a  $C_6H_{12}O_6$  group more than arabic acid. (b) To the character and position of the  $C_6H_{12}O_6$  group in the acid from the  $C_{20}H_{128}O_{227}$  body upwards. Kiliani (*l.c.*) shows that different varieties of gum yield, when oxidised with  $HNO_3$ , proportions of mucic acid varying between 14.3 and 38.3 p.c., thus indicating a difference in the number of galactose ( $\gamma$ -arabinose)-yielding groups they contain (see also Scheibler). And (c) possibly to the structure of the  $C_{20}H_{128}O_{227}$  group itself. The gums, too, vary much in the character of the solutions they yield (Gm. 15, 194); some give a thin syrupy solution, others a thick and jelly-like one; this is due to the varying proportion of the acid naturally converted into the meta-modification—the gums which yield the thinnest solutions are those which contain the greatest amount of ash. Gums from the same source have not always the same optical activity; Scheibler found the beet gum of one season +, and of another —; Kiliani states that East Indian gum, and gum arabic elect. are +, the samples of these gums examined by O'Sullivan were —; the sample of Australian gum examined by the former was +, that by the latter, inactive. From this it would appear that the same plant does not produce the same gum in every season, but, on the whole, it is fairly certain that the acids of all the gums are constituted in the same way as arabic acid described above.

**Combinations.**—The arabic salts of the alkaline earths are prepared by exactly neutralising moderately strong solutions of the pure acid with clear solutions of the earthy salt of which is required, precipitating with alcohol,

<sup>1</sup> According to Kiliani (*B. 20*, 339a, 1233) the formula of arabinose is  $C_6H_{12}O_6$ ; should this prove to be so, the formula of arabic acid and of the arabinosio acids must be diminished by a  $CH_2O$  group for every molecule of arabinose-yielding group they contain.

treating the pp. with strong alcohol until it admits of being powdered, collecting the powder on a filter, pressing, and drying over sulphuric acid. The Ba salt contains  $C_{20}H_{128}O_{227} \cdot BaO$  (6.0 p.c. BaO) and the CaO salt,  $C_{20}H_{128}O_{227} \cdot CaO$  (2.28 p.c. CaO). When the syrupy solutions of these salts are allowed to dry spontaneously they yield glassy, transparent masses, like natural gums; the salts of the arabinosio acids yield similar bodies.

**ARABITE**  $C_6H_{12}O_6$ , which is probably  $CH_2(OH) \cdot CH(OH) \cdot CH(OH) \cdot CH(OH) \cdot CH_2(OH)$ . *Penta-ory-n-pentane*. [102°]. Obtained by reduction of arabinose with sodium-amalgam, keeping the solution carefully neutralised. Small prisms or needles. V. sol. water and hot 90 p.c. alcohol, v. sl. sol. cold alcohol. Sweet taste. Does not reduce Fehling's solution. Does not lose water at 100° (diff. from sorbite) (Kiliani, *B.* 20, 1233).

**ARABONIC ACID** v. **TETRA-OXY-VALERIC ACID.**

**ARACHIC ACID**  $C_{26}H_{50}O_2$ . Mol. w. 312. [75.6°]. *Arachidic acid*.

**Occurrence.**—1. In the oil from the ground nut *Arachis hypogaea*, from which it is obtained after saponification (Gössmann, *A.* 89, 1).—2. In butter (Heintz, *P.* 90, 146).—3. As glyceryl ether in the fruit of *Nephelium lappaceum* (Oudemans, *J. pr.* 99, 407).

**Formation.**—1. By potash-fusion from brassidic acid (Goldschmidt, *J.* 1877, 728).—2. From stearic acid by converting it into the corresponding alcohol,  $C_{17}H_{35}CH_2OH$ , and iodide  $C_{17}H_{35}CHI$ . The latter gives octadecyl aceto-acetic ether when treated with sodio-aceto-acetic ether, and alcoholic KOH thence produces arachic acid (Schweizer, *Ar. Ph.* [3] 22, 753).

**Properties.**—Small shining plates; v. sol. boiling alcohol, and ether; insol. water. Gives a nitro-, [70°], and an amido- [59°], arachic acid.

**Salts.**—(Scheven a. Gössmann, *A.* 97, 257).  $AgA'$ : prisms (from alcohol)— $CuA'_2$ : needles (from alcohol)— $BaA'_2$ : hardly soluble in alcohol.— $SrA'_2$ — $MgA'_2$ : crystalline powder (from alcohol).— $KA'$ : usually gelatinous.

**Methyl ether.** [55°]. Scales (Caldwell, *A.* 101, 97); [53°] (Schweizer).

**Ethyl ether.** [49.5°]. (296°) at 100 mm.

**Iso-amyl ether.** [45°]. Scales.

**Arachins.** Prepared artificially by heating arachic acid with glycerin (Berthelot, *A. Ch.* [3] 47, 355); they are insol. ether. Di-arachin  $C_2H_5(OH)(OC_{26}H_{50}O)_2$  melts at [75°].

**Arachyl chloride**  $C_{26}H_{50}O.Cl$ . [67°]. Unstable (Tassinari, *B.* 11, 2031).

**Arachamide**  $C_{26}H_{50}O.NH_2$ . [99°]. Prisms grouped in stars; insol. water, sol. hot alcohol (Gössmann a. Scheven, *A.* 97, 262).

**Acetic-arachic anhydride**  $C_{26}H_{50}O.O.Ac$ . [60°]. From  $AcCl$  and potassium arachate. Scales (from ether) (T.).

**Valeric-arachic anhydride**  $C_{26}H_{50}O.O.C.H_2O$  [68°] (T.).

**ARALEIN.** The bark of *Aratia spinosa* contains a tannin which gives a green colour with  $FeCl_3$ , and a glucoside called aralein. The latter is a neutral, light-yellow substance, sol. water and alcohol, insol. ether, benzene, and  $CHCl_3$ . Gives no pp. with lead acetate,  $HgCl_2$ , or  $PbCl_2$ . Boiling dilute  $HCl$  converts it into white aral-retin, insol. water (Holden, *Ph.* [3] 11, 210).

**ARBOL-A REHA RESIN.**—The product of a tree (*Canarium album*) growing in the Philippine Islands (Maujean, *J. Ph.* 9, 45; Bonastre, *J. Ph.* 10, 199). Baup (*J. pr.* 55, 88) finds four crystalline substances in it: Amyrin [174°]; Breidin, S. 39 at 20°; Brein [187°]; and Bryoidin [185°].

**ARBUTIN**  $C_{12}H_{16}O_6$ ,  $\frac{1}{2}$  aq. [166°].

**Occurrence.**—Together with methyl-arbutin in the leaves of the red bearberry, *Arctostaphylos Uva Ursi* (Kawaler, *A.* 82, 241; 84, 356), and in the leaves of a species of winter-green, *Pyrola umbellata* (Zwenger a. Himmelmann, *A.* 129, 203).

**Preparation.**—The aqueous infusion of the leaves is ppd. by lead acetate, excess of lead removed by  $H_2S$ , the filtrate evaporated and the arbutin extracted and crystallised by a mixture of ether (8 pts.) and alcohol (1 pt.). The product is a mixture of arbutin and methyl-arbutin, which can be separated by crystallisation from water (H. Schiff, *G.* 11, 99; 13, 538; *A.* 221, 365; cf. Habermann, *M.* 4, 753).

**Properties.**—Long glistening needles which melt at 165°, but, on second fusion, at 187° (H. Schiff, *B.* 11, 304; *A.* 206, 159). V. sol. alcohol and boiling water, v. sl. sol. ether. Its aqueous solution gives no pp. with lead acetate or subacetate. Does not reduce alkaline cupric solution. Dilute  $Fe_2Cl_6$  gives a blue colour.

**Reactions.**—1. Split up by emulsion or by boiling dilute  $H_2SO_4$  into hydroquinone and glucose (Strecker, *A.* 107, 229).—2.  $H_2SO_4$  and  $MnO_2$  form quinone.—3. Converted by  $Ag_2O$  into water and di-arbutin, an extremely soluble syrup, whence arbutin can be recovered by reduction with Zn and  $H_2SO_4$  (Schiff, *A.* 154, 214).—4. Chlorine passed into an aqueous solution forms di- and tri-chloro-quinones (Strecker, *A.* 118, 295).

**Acetyl derivative**  $C_{12}H_{14}Ac_2O_7$ . Plates or needles (from alcohol), insol. water.

**Benzoyl derivative**  $C_{12}H_{14}Bz_2O_7$ . Crystalline powder, sl. sol. alcohol.

**Di-nitro-arbutin**  $C_{12}H_{14}(NO_2)_2O_7$ . Golden needles (from water); insol. ether (Hlasiwetz, a. Habermann, *A.* 177, 313). Gives an orange pp. with lead subacetate. Boiling dilute  $H_2SO_4$  gives di-nitro-hydroquinone. Converted by  $Ac_2O$  into  $C_{12}H_{14}Ac_2(NO_2)_2O_7$ .

**Methyl-arbutin**  $C_{10}H_{14}O_5$ , i.e.

$C_6H_5O(OH).O.C_2H_5.OMe$ . [169°] (Michael); [175°] (Schiff). Occurs in nature associated with arbutin. Formed synthetically by the action of acetoethylhydrose upon potassium hydroquinone methyl ether,  $KO.C_2H_5.OMe$  (Michael, *Am.* 5, 178; *B.* 14, 2097). Also from crude arbutin by converting the free arbutin into methyl-arbutin (by MeI and KOH) or into benzyl-arbutin (H. Schiff, *G.* 12, 464; *A.* 221, 366).

**Properties.**—Colourless silky needles, with bitter taste. Contain aq and melt at 169° (Michael); contain  $\frac{1}{2}$  aq and melt at 175° (Schiff). Sol. water and alcohol, v. sl. sol. ether. Gives no blue colour with  $Fe_2Cl_6$ .

**Benzyl-arbutin**  $C_{18}H_{22}O_6$ , i.e.

$PhCH_2O.C_2H_5O.C_6H_5O_3$  aq. [161°]. S. 19 at 23°. From  $PhCH_2Br$ , commercial arbutin (containing methyl-arbutin), and KOH in boiling alcohol. Excess of KOH is removed by  $CO_2$ , and after evaporating and adding water, benzyl-arbutin

is ppd. while methyl-arbutin remains in solution. Arborescent needles. Soluble in boiling water, very soluble in alcohol. Does not reduce Fehling's solution, except after short boiling with  $H_2SO_4$ , which splits it up into glucose and benzyl-hydroquinone. Gives on nitration yellow needles which are benzyl-nitro-arbutin,  $C_{18}H_{21}(NO_2)_2O_6$ , [148°], split up by dilute  $H_2SO_4$  into glucose and benzyl-nitro-hydroquinone (Schiff a. Pellizzari, *A.* 221, 365).

**Isoamyl-arbutin.** From the mixture of arbutin and methyl-arbutin by amyl bromide and NaOH (S. a. P.). Needles. On decomposition gives iso-amyl-hydroquinone and glucose.

**ARCHIL** or *Orseille* is a purple dyo obtained from various lichens (*Rocella*, *Lecanora*, and *Variolaria*) containing acids (erythric, lecanoric, &c.), which on decomposition yield orcin (*q. v.*) which is converted by air and ammonia into red orcein. When  $K_2CO_3$  or  $Na_2CO_3$  as well as ammonia is added to the lichens litmus is produced.

**ARGININE**  $C_6H_{13}N_3O_2$ . Easily soluble in water; reacts alkaline. Occurs to the extent of about 3-4 p.c. in the young shoots of the lupine (*lupinus luteus*). The shoots are extracted with water; tannin and lead acetate are added to the extract; the filtrate is acidified with  $H_2SO_4$ , again filtered, and ppd. with phosphomolybdic acid; the pp. is washed and treated with cold milk of lime, and the solution of the base finally neutralised with  $HNO_3$  and evaporated to crystallisation.

**Salts.**— $B'HNO_3$ ,  $\frac{1}{2}$  aq: slender white soluble needles; with phosphomolybdic acid it gives a white pp. soluble in hot water; with picric acid a yellow crystalline pp. is formed on standing. —  $B'HI$ : large crystals. —  $B'_2Cu(NO_3)_2$  3aq: formed by heating a solution of the nitrate with cupric hydrate; dark-blue prisms, sl. sol. cold water (Schulze a. Steiger, *B.* 19, 1177).

**ARGOL.** Crude acid potassium tartrate deposited from wine.

**ARGYRESCIN**  $C_{27}H_{40}O_{12}$ . A glucoside in the cotyledons of the horse-chestnut. Minute tables (from dilute alcohol). Split up by dilute HCl into argyrescetin  $C_{25}H_{38}O_8$  and glucose. Potash produces propionic acid and asemic acid (*q. v.*) (Roehleder, *J. pr.* 87, 1; 101, 415).

**ARIBINE**  $C_{21}H_{29}N_3$ . S. 12.9 at 23°. A base extracted by dilute  $H_2SO_4$  from the bark of *Arariba rubra*, the solution being treated with lead acetate and the base dissolved in ether, from which it separates as anhydrous pyramids or (with 8 aq) as four-sided prisms. V. sol. water and alcohol, m. sol. ether (Rüch a. Wöhler, *A.* 120, 217). **Salts.**— $B''2HCl$ . —  $B''H_2PbCl_4$ . —  $B''H_2SO_4$ . —  $B''2H_2SO_4$ .

**ARICINE**  $C_{23}H_{31}N_3O_2$ . [188°]. S. (ether) 5 at 18°. 'Cusconine,' *Cinchonarine*. Yellow Cusco bark contains 24 p.c. aricine and 37 p.c. cusconine. Occurs also in bark of cinchona eupraea (Hesse, *Ph.* [3] 12, 517). Prisms (from dilute alcohol); insol. water, v. e. sol. chloroform, m. sol. ether, v. sl. sol. alcohol. Solutions are not fluorescent. Levorotatory in alcoholic or ethereal solutions; its solution in dilute HCl is inactive. In a 1 p.c. ethereal solution  $[\alpha]_D^{20} = -94.8^\circ$ ; in a 1 p.c. alcoholic (97 p.c.) solution  $[\alpha]_D^{20} = -54^\circ$ . Aricine is turned dark green by conc.  $HNO_3$ . Bleaching-powder and  $NH_3$  only give a yellowish colour.

**Salts.**— $BHCl_2$  aq. —  $B'H_2PtCl_6$  aq. —  $3H$ . —  $B'HNO_3$ . —  $B'H_2SO_4$ : slender needles, n. sol. cold water. —  $B'H_2SO_4$ : small prisms, v. l. sol. cold water. —  $B'H_2OAc$  aq.: grains, v. al. ol. cold water. —  $B'H_2CO_3$  aq.: white prisms, quickly changing to rhombohedra, S. 049, sl. ol. hot alcohol. —  $B'HSCy$ . — Salicylate  $VO_2H_2O_2$  aq.

**References.**—Pelletier, *A. Ch.* [2] 42, 330; 1, 185; Pelletier a. Corriol, *J. Ph.* [2] 15, 575; everköhn, *Repert. f. Pharm.* 83, 357; Manzini, *Ph.* [3] 2, 95; Howard, *Ph.* [3] 5, 908; Hesse, 160, 259; 181, 58; 185, 321; 200, 803.

**ARNICIN**  $C_{10}H_{10}O_4$  (?). An amorphous substance present in the root, leaves, and blossoms of *Arnica montana* (Walz, *N. Jahrb. Pharm.* 3, 175; 14, 79; 15, 329).

**AROMATIC SERIES.** Substances whose molecules contain a benzene nucleus are said to belong to the aromatic series.

Elements attached to a carbon atom belonging to the benzene nucleus are more firmly fixed than when attached to a carbon atom not in that nucleus: in the former case the derivative (called an *exo* derivative) has the character of a derivative of benzene, in the latter case the derivative (called an *endo* derivative) behaves like a fatty compound. Thus *exo*-chloro-toluene (benzyl chloride)  $C_6H_5CH_2Cl$  behaves like ethyl chloride, being readily converted into an alcohol, amine, or cyanide, by treatment with  $KOH$ ,  $NH_3$ , or  $KCN$ , respectively; while *endo*-chloro-toluene,  $C_6H_4CH_2Cl$ , is not affected by these reagents.

It must, however, be added that the ease with which a given atom or radicle in the molecule of an aromatic compound may be displaced depends not only upon its position in relation to the carbon atoms but also upon the existence and position of other elements or radicles in the molecule. Thus *o*- and *p*-, but not *m*-, chloro-nitro-benzene are converted by hot aqueous potash into nitro-phenols, and by  $NH_3$  into nitro-anilines; while chloro-phenols and chloro-benzene sulphonic acids are converted into di-*xy*-benzenes by potash-fusion.

Halogens acting upon cold hydrocarbons in the presence of carriers (such as I) enter the benzene nucleus, but when acting alone upon hydrocarbons at  $100^\circ$  or upwards they enter a side chain (*exo* position). Direct sunlight has the same effect as elevation of temperature, but its effect is entirely counteracted by the presence of iodine (Schramm, *B.* 18, 606). Halogens attack a benzene nucleus that already contains hydroxyl, amidogen, or  $SO_3H$ , with much greater vigour than when its carbon atoms are united only to hydrogen and carbon.

Conc.  $HNO_3$  and conc.  $H_2SO_4$  attack aromatic compounds,  $NO_2$  and  $SO_3H$  displacing H in the nucleus; they do not act upon fatty compounds in this way.

The constitution of the molecule of benzene, and the methods by which the relative position of elements or radicles in the molecules of its derivatives have been determined will be discussed in another article, v. BENZENE.

**Laws of Substitution.**—I. When one of the following radicles has displaced one of the atoms of hydrogen in the benzene molecule, forming the compound  $C_6H_5A$ , any new group on enter-

ing will take up a position *meta* to A. Here A may be  $CO_2H$ ,  $SO_3H$ , or  $NO_2$ , and probably also  $CN$ ,  $CHO$ ,  $SO_3Ph$ , and  $CO_2CH_3$  (Hubner, *B.* 8, 873; Nölting, *B.* 9, 1797; cf. Armstrong, *C. J.* 51, 259; Morley, *C. J.* 51, 579).

II. If in a substituted benzene,  $C_6H_5B$ , the substituting element or radicle be not one of the foregoing, then any new group on entering will take up an *ortho* or a *para* position: usually chiefly *p* with a little *o*. Examples of B are  $NH_2$ ,  $NHAc$ ,  $OH$ ,  $Cl$ ,  $Br$ ,  $I$ ,  $CH_3$ , and all chains of carbon atoms except such as begin with  $CO$ .

These laws tell the chief product of the substitution of isomerides at variance with the order of formation.

The radicles that induce *meta* substitution are all composed of an element (N, C, or S) united to a chlorous group;  $CCl_3$  is also a radicle of this kind, and it gives a *m*-nitro-derivative, but it also gives a *p*-chloro-derivative.

The radicles that induce *p* or *o* substitution are either single elements, or elements united to basylous elements or groups. The radicles  $CH_2Cl$  and  $CHCl_2$  are intermediate in character; the latter appearing to resemble  $CCl_3$ , the former resembling  $CH_3$ . Armstrong points out that the radicles producing *m* derivatives are unsaturated, and might form additive compounds before substitution takes place.

Amido compounds in presence of excess of  $H_2SO_4$  (20 pts.) when treated with the calculated quantity of  $HNO_3$  dissolved in  $H_2SO_4$ , added at  $0^\circ$ , give chiefly *meta*-nitro derivatives, some of the *p*-nitro derivative being also formed. Examples: aniline, acetanilide, toluidine, xylydine, *p*-bromo-aniline (Nölting a. Collin, *B.* 17, 261), di-methyl-aniline, di-ethyl-aniline (Groll, *B.* 19, 198), ethyl-aniline (Nölting a. Strecker, *B.* 19, 546). The amount of *meta*-nitro derivative formed is increased by increasing the quantity of sulphuric acid present. In all these cases nitrogen is attached to a chlorous radicle, aniline sulphate being  $C_6H_5N(O.SO_3H)_2$ , and might therefore be expected to produce a *meta* derivative. It is, however, curious that a solution of aniline sulphate in a small quantity of sulphuric acid gives very little *m*-nitraniline on nitration.

When a new element or radicle enters a benzene nucleus in which more than one H is already displaced if it can satisfy the requirements of each of the substituents already present it will do so; if not it obeys the most powerful substituent present. The following appears to be the order of priority, beginning with the strongest:

$HO$ ;  $NH_2$ ; halogens;  $CH_3$ ; other alkyls;  $NO_2$ ;  $CO_2H$  and  $SO_3H$ . The conversion of *p*-nitro-phenol into  $C_6H_4(OH)Br(NO_2)$  [1:2:4], and that of *o*-nitro-phenol into  $C_6H_4(OH)Br(NO_2)$  [1:5:2], by the action of Br are instances where both  $NO_2$  and  $OH$  are obeyed; but in the action of Br upon *p*-bromo-phenol and of  $HNO_3$  upon  $C_6H_4(OH)Cl_2$  [1:2:4] the new substituent obeys the stronger radicle, producing  $C_6H_3(OH)Br_2$  [1:2:4:6] and  $C_6H_3(OH)Cl_2(NO_2)$  [1:2:4:6] respectively.

When a hydrocarbon radicle is introduced by the agency of  $AlCl_3$ , it does not always follow the foregoing rule; thus *m*-xylene is the chief product of the action of  $MeCl$  upon benzene in presence of  $AlCl_3$ .

*Differences between o, m, and p compounds.*

Ortho, meta, and para compounds usually boil at about the same temperature, but the para compounds have the highest melting-points. The ortho compounds are usually the most, and the para compounds the least, volatile with steam. In the oxidation of ortho compounds the benzene ring is liable to be broken up, while in the meta and para compounds this is not the case (v. HYDROCARBONS). Ortho compounds readily give rise to products of condensation in which the side chains may be supposed to be joined in the form of a ring; this tendency is observed to some extent in the para series but not at all in the meta series. Thus by loss of  $\text{H}_2\text{O}$  *o*-amido-phenyl-glyoxylic acid gives isatin; *o*-amido-cinnamic acid gives carbostyryl, *o*-oxycinnamic acid gives coumarin; phthalic acid gives phthalic anhydride.

*o*-nitraniline hydrochloride is readily decomposed by water, *p*-nitraniline hydrochloride less so, and *m*-nitraniline hydrochloride is hardly decomposed by water (Lellmann, *B.* 17, 2719). In general, the introduction of a radicle into the *m*-position produces less change in the properties of a compound than the introduction of the same radicle into the *o* and *p* position, and of the resulting derivatives the meta are the most stable. Thus *m*-xylene is oxidised with difficulty, while dilute  $\text{HNO}_3$  readily converts *o*-, and *p*-, xylene into toluic acids. Ortho-, and para-, oxybenzoic acids are converted into phenol by heating with aqueous  $\text{HCl}$  in sealed tubes, while *m*-oxybenzoic acid, like benzoic acid itself, is unaffected. Ammonia converts *o*- and *p*-nitroanisols into nitranilines, but does not affect *m*-nitro-anisol or anisol itself; similarly ammonia converts *o*-, and *p*-, bromo-nitro-benzenes into nitranilines, but does not affect *m*-bromo-nitro-benzene or bromo-benzene itself. Boiling alkalis convert *o*-, and *p*-, nitraniline into nitrophenols, but do not affect *m*-nitraniline or aniline. Aniline and *m*-nitraniline resemble one another in readily uniting with phenyl thio-carbimide (forming diphenyl-thio-urea and nitro-di-phenyl-thio-urea respectively), while *p*-, and *o*-, nitraniline require to be heated for some time with phenyl thio-carbimide before they will combine. Benzoic acid and *m*-oxy-benzoic acid are readily reduced by sodium-amalgam to benzyl alcohol and *m*-oxy-benzyl alcohol respectively, while *o*-, and *p*-, oxybenzoic acids are not attacked. Ortho- and para-nitro-acetanilide dissolve in conc. potash; the former is readily saponified by the potash, giving potassium acetate and *o*-nitro-aniline; a similar decomposition occurs with the latter, but with greater difficulty. Meta-nitro-acetanilide is insoluble in conc. potash, and is scarcely affected by it (Kleemann, *B.* 19, 336). The substitution of an atom of hydrogen in the nucleus by an atom of bromine is accompanied by absorption of heat; in an actual experiment this is not observed, being more than counterbalanced by the heat developed in the simultaneous formation of  $\text{HBr}$  (Werner, *Bl.* 46, 282).

*Occasional reactions.*

1. Acetyl bromide not only displaces  $\text{H}$  by  $\text{Ac}$  but sometimes even turns out an alkyl; thus it converts di-methyl-aniline and di-ethyl-aniline

into methyl acetanilide, and ethyl-acetanilide respectively (Staedel, *B.* 19, 1947).—2. Benzoyl chloride sometimes behaves in the same way, converting di-methyl-aniline and di-ethyl-aniline into methyl-benzanilide and ethyl-benzanilide respectively.—3. Nitric acid in nitration sometimes turns out acetyl, converting ethyl acetanilide into  $\text{C}_6\text{H}_5(\text{NO}_2)_2\text{NEtH}$  [1:3:4], and behaving similarly towards methyl acetanilide (Norton, *B.* 18, 1997). Nitric acid sometimes turns out bromine; thus it converts *p*-bromo-aniline into tri-nitro-aniline (picramide) (Hager, *B.* 18, 2578).—4. Potash converts di-nitro-di-methyl-aniline,  $\text{C}_6\text{H}_3(\text{NO}_2)_2\text{NMe}_2$  [4:2:1] into di-nitro-phenol, di-methyl-amine being given off.

*Molecular changes.*

At high temperatures *o*-compounds may change to *p*-, and both *o*- and *p*- to *m*-. At  $100^\circ$  *o*-phenol-sulphonic acid changes to *p*-phenol-sulphonic acid. At  $220^\circ$  potassium salicylate changes to *p*-oxybenzoate, while sodium salicylate is not affected at that temperature. Resorcin is obtained by potash-fusion from benzene *p*-disulphonic acid, *p*-chloro-benzene sulphonic acid, and *o*- and *p*-bromo-phenol.

Methyl can pass from combination with nitrogen into the nucleus; thus dimethylaniline methylo-iodide at  $220^\circ$  gives *o*- and *p*-dimethyl toluidine, methyl-xylylidine, and di-methyl-xylylidine; while at  $335^\circ$  it gives  $\psi$ -cumidine,  $\text{C}_6\text{H}_4\text{Me}_2\text{NH}_2$  (Hofmann, *Pr.* 21, 47).

Ethyl aniline hydrochloride at  $320^\circ$  changes similarly to ethyl-phenyl-amine,  $\text{C}_6\text{H}_5\text{EtNH}_2$ , while isoamyl-aniline hydrochloride becomes isoamyl-phenyl-amine,  $\text{C}_6\text{H}_5(\text{C}_4\text{H}_9)\text{NH}_2$  (Hofmann, *B.* 7, 526). In these cases it may be supposed that  $\text{MeI}$ ,  $\text{MeCl}$ ,  $\text{EtCl}$ , and  $\text{C}_4\text{H}_9\text{Cl}$  respectively are split off and then attack the nucleus; this action of  $\text{MeCl}$  is seen in the conversion of xylylidine hydrochloride into  $\psi$ -cumidine by heating with methyl alcohol at  $280^\circ$  (Hofmann, *B.* 13, 1730).

*Conversion of fatty compounds into aromatic.*

1. By passing acetylene (*q. v.*) through a red hot tube.—2. By heating acetone or allylene with sulphuric acid mesitylene is formed.—3. Uvitic acid,  $\text{C}_6\text{H}_4\text{Me}(\text{CO}_2\text{H})_2$  [1:3:5] is formed by boiling pyruvic acid with baryta.—4. Oxy-uvitic ether is formed by the action of chloroform on sodium aceto-acetic ether.—5. Succinyl-succinic ether from succinyl chloride, sodium, and succinic ether is di-oxy-di-hydro-terephthalic ether; when heated with  $\text{KOH}$  it gives hydroquinone. Hydroquinone is also formed when succinates are subjected to dry distillation.—6. Phloroglucin tri-carboxylic ether is formed by the action of sodium or of  $\text{ZnEt}_2$  on malonic ether (Baeyer, *B.* 18, 3457; Lang, *B.* 19, 2937). 7. Tri-mesic ether is formed by the action of sodium on a mixture of formic and acetic ether (Piutti, *B.* 20, 537).—8. Hexyl iodide and bromine at  $200^\circ$  gives hexa-bromo-benzene (Krafft, *B.* 9, 1085; 10, 801).—9.  $\text{K}$  and  $\text{CO}$  combine, forming  $\text{C}_6(\text{OK})_6$  (Nietzki a. Benckiser, *B.* 18, 1833).

*Conversion of aromatic compounds into fatty.*

1. Carbonic, oxalic, and formic acids are products of oxidation of aromatic compounds.—

2. Benzene is converted by  $\text{KClO}_3$  and  $\text{HCl}$  into  $\text{C}_6\text{H}_4\text{Cl}_2\text{O}_3$ , which is converted by baryta into fumaric acid.—3. Nitrous acid converts pyrocatechin in ethereal solution into dioxytartaric acid.—4.  $\text{HCl}$  and  $\text{KClO}_3$  convert gallic acid into tri-chloro-glyceric acid.—5. Chlorine passed into a cold aqueous solution of phloroglucin gives dichloro-acetic acid (Hlasiwetz a. Habermann, *A.* 155, 132).

**Aromatic acids.** The principal aromatic acids are those containing  $\text{SO}_3\text{H}$  and those containing  $\text{CO}_2\text{H}$ . The former will be discussed as SULPHONIC ACIDS, the latter will be briefly characterised here (v. also ACIDS, AMIDO-, BROMO-, CHLORO-, IODO-, and NITRO-acids).

**Formation.**—1. By oxidation of homologues of benzene or derivatives of such homologues.  $\text{K}_2\text{Cr}_2\text{O}_7$  (2 pts.),  $\text{H}_2\text{SO}_4$  (3 pts.), and water (3 to 5 pts.), is a convenient mixture for the purpose; but it converts all side chains into carboxyls, thus *m*- and *p*-xylene become iso-, and *tert*-, phthalic acids, while mesitylene becomes trimelic acid. Dilute  $\text{HNO}_3$  (S.G. 1.2) and aqueous  $\text{KMnO}_4$  oxidise more gradually, attacking one side chain at a time, thus converting *o*- and *p*-xylene into *o*- and *p*-toluic acid and mesitylene into mesitylenic acid.—2. By passing  $\text{CO}_2$  over a mixture of a bromo-derivative and sodium:  $\text{C}_6\text{H}_4\text{Br} + \text{CO}_2 + \text{Na}_2 = \text{C}_6\text{H}_4\text{CO}_2\text{Na} + \text{NaBr}$  (Kekulé, *f.* 137, 178).—3. By heating a bromo-derivative with chloroformic ether and sodium, thus:  $\text{C}_6\text{H}_4\text{Br} + \text{ClCO}_2\text{Et} + \text{Na}_2 = \text{C}_6\text{H}_4\text{CO}_2\text{Et} + \text{NaCl} + \text{NaBr}$  (Wurtz, *A. Suppl.* 7, 125).—4. By the action of  $\text{COCl}_2$  or  $\text{CO}_2$  on aromatic hydrocarbons in presence of  $\text{AlCl}_3$  (Friedel a. Crafts, v. ALUMINIUM CHLORIDE, p. 147) the product being treated with water. The amides may be produced in a similar way by using  $\text{Cl.CO.NH}_2$  instead of  $\text{COCl}_2$  (Gattermann a. Schmidt, *B.* 20, 58).—5. By heating sulphonates with sodium formate:  $\text{PhSO}_3\text{K} + \text{HCO}_2\text{Na} = \text{Ph.CO}_2\text{Na} + \text{HSO}_2\text{K}$  (V. Meyer, *A.* 156, 273).—6. By saponification of nitriles. The nitriles may be obtained either by heating sulphonates or *ortho*-chloro derivatives with potassium cyanide or by heating thio-carbimides with copper (Weith, *B.* 6, 212). Nitriles may also be obtained by distilling the formyl derivatives of amines with zinc-dust, e.g.:  $\text{hNH}_2\text{CHO} = \text{H}_2\text{O} + \text{PhCN}$ .—7. By oxidation ofcohols or aldehydes.—8. Aromatic acids containing carboxyl in the side chain can be prepared by synthesis with acid of aceto-acetic ether (v.) or of malonic ether (q. v.).—9. Oxy-acids are formed by boiling diazo-acids with water, or by potash-fusion from chloro-, bromo-, iodo-, or sulpho-, acids.—10. By passing  $\text{CO}_2$  into sodium phenols at  $180^\circ$  or potassium phenol; in the former case  $\text{CO}_2\text{H}$  takes up a position ortho to the hydroxyl. Potassium phenol at  $140^\circ$  gives salicylic acid, but at  $170^\circ$ – $200^\circ$  it gives *p*-oxy-benzoic acid. The reaction takes place in two stages:

**v. OXY-BENZOIC ACIDS.**—11. By heating phenols with dilute alcoholic solution of  $\text{CCl}_4$  and  $\text{NaOH}$  at  $100^\circ$ :  $\text{C}_6\text{H}_5\text{OH} + \text{CCl}_4 + 6\text{NaOH} = \text{C}_6\text{H}_4(\text{ONa})\text{CO}_2\text{Na} + 4\text{NaCl} + 4\text{H}_2\text{O}$  (Tiemann a. Reimer, *B.* 9, 1285). The carboxyl takes up positions para and ortho to the hydroxyl.—

12. Perkin's synthesis of cinnamic acid and its homologues is described and discussed in the article on ALDEHYDES.—13. Resorcin and its homologues are converted into (1, 3, 4) and (1, 3, 2) di-oxy-benzoic acids and their homologues by heating with ammonium carbonate and water; while hydroquinone and its homologues heated with potassium bicarbonate, water, and a little  $\text{K}_2\text{SO}_4$  give (1, 4, 2) di-oxy-benzoic acid and its homologues (Senhofer, *Sitz. B.* 80, 504; 81, 430, 1044; *M.* 2, 448).

**Reactions.**—1. The aromatic acids are subject to the general laws governing substitution in the benzene nucleus.—2. They are usually sl. sol. water but v. sol. alcohol and ether. The homologues of benzoic, and of salicylic, acid are volatile with steam, *m*-, and *p*-, oxy-benzoic acids are not volatile with steam. Salicylic acid and its homologues are soluble in chloroform, *p*-oxy-benzoic acid and its homologues are not. Ortho-oxy-acids are also characterised by giving a violet colouration with  $\text{FeCl}_3$ .—3. Ortho-oxy-acids of the form  $\text{C}_6\text{H}_4(\text{OH}).\text{CH}_2.\text{CO}_2\text{H}$  or  $\text{C}_6\text{H}_3(\text{OH}).\text{CH}_2.\text{CO}_2\text{H}$  have a tendency to produce anhydrides or lactones; ortho-amido acids of the form  $\text{C}_6\text{H}_4(\text{NH}_2).\text{CH}_2.\text{CO}_2\text{H}$  or  $\text{C}_6\text{H}_3(\text{NH}_2).\text{CH}_2.\text{CO}_2\text{H}$  readily form anhydrides, similarly called lactams:  $\text{C}_6\text{H}_4\text{CH}_2\text{CO}_2\text{H} \rightarrow \text{C}_6\text{H}_4\text{CH}_2\text{CONHCO}_2\text{H}$ .

or lactams:  $\text{C}_6\text{H}_4\text{CH}_2\text{CO}_2\text{H} \rightarrow \text{C}_6\text{H}_4\text{CH}_2\text{CONHCO}_2\text{H}$ .—4. Benzene is produced by fusion with  $\text{NaOH}$  from benzoic acid (75 p.c.), trimellitic acid, hydrocinnamic acid, and cinnamic acid (50 p.c.); a little diphenyl is also formed. Fusion with  $\text{NaOH}$  converts *o*-, and *p*-, oxy-benzoic acids into phenol (50 to 60 p.c.); protocatechuic acid into resorcin (50 to 60 p.c.); (1, 3, 5)-di-oxy-benzoic acid into resorcin (60 p.c.), phlorctic acid and *p*-coumaric acid into *p*-oxy-benzoic acid and finally into phenol; oxy-terephthalic acid into salicylic and *p*-oxy-benzoic acids, and finally into phenol (Barth a. Schreder, *B.* 12, 1255).

**Aromatic bases.** The preparation and properties of the aromatic bases have been discussed in the article on AMINES. They may be divided into two classes according as the nitrogen is attached to carbon in a benzene nucleus or in a side chain; bases of the latter form resemble fatty amines. Amines containing amidogen attached to the benzene nucleus are weakened in basic power by introduction of nitroxyl or halogens into the nucleus, more especially if these radicles do not occupy a position meta to the amidogen. Trichloraniline, dinitraniline, and trinitraniline do not combine with acids; the latter is even saponified by potash with formation of trinitrophenol.

**ARSENATES.** Salts of arsenic acid, v. ARSENIC ACIDS OF, p. 305.

**ARSENIC.** As (*Arsenicum*, *Regulus arsenici*, *ἀρσενικόν*). By the term *σάββαλον* Aristotle seems to mean a compound of arsenic and sulphur, called *ἀρσενικόν* by Theophrastus). At. w. 74.9. Mol. w. 299.6; 149.8 at c.  $1700^\circ$  (Biltz a. Meyer, *B.* 22, 725). Melts only under great pressure (Landolt; also Mallet, *C. R.* 26, 97). S.G. 5.23 to 5.76; pure, crystalline  $14^\circ$  5.720–5.723; grey, pearly crystals  $14^\circ$  4.71 (Bettendorff, *A.*

144, 110); amorphous  $\frac{140}{19}$  4-710-4-716 (*ibid.* *l.c.*); fused  $\frac{190}{19}$  5-709 (Mallet, *C. R.* 26, 97). V.D. 147-2 at 860° (Deville a. Troost, *C. R.* 56, 871); 153-7 at 640-670° (Mitscherlich, *A.* 12, 159). S.H. crystallised, -083; black, amorphous, -0758 (Bettendorff a. Willner, *P.* 133, 293). C.E. (linear at 40°) -00000559 (Fizeaux, *C. R.* 68, 1125). E.C. (Hg at 0°=1) 2-679 at 0°, 1-873 at 100° (Matthiessen a. Bose, *T.* 152, 1). S.V.S. cryst. 13-1; amorph. 15-9.  $\frac{\mu_a - 1}{d} \times \text{at. wt.}$  15-4 (Gladstone, *Pr.* 18, 49).

Chief lines in emission spectrum, *v.* Huntington, *P. Am. A.* [2] 9, 34; Hartley a. Adeney, *T.* 1884, 121.

*Occurrence.*—Found native, but more frequently associated with other metals and sulphur, in widely distributed ores. Obtained as a principal product chiefly from *native arsenic*, *arsenical iron*  $\text{FeAs}_2$  and  $\text{FeAs}_3$ , and *arsenical pyrites*  $\text{FeAsFeS}_2$ ; obtained as a secondary product from *smaltine*, *cobalt glance*, *arsenical cobalt*, *nickel glance*, many *fahl-ores*, &c. Occurs also in ferruginous deposits of certain mineral waters (Will, *A.* 61, 192); in nearly all iron ores (Walchner, *A.* 61, 205); in soils, from the weathering of iron pyrites (Sonnenschein, *Ar. Ph.* [2] 143, 215); in the residue obtained by evaporating sea water (Daubrée, *Ann. M.* [4] 19, 669); frequently found in metallic bismuth (Schneider, *J. pr.* [2] 20, 418); in various kinds of pyrites, and hence in most samples of commercial sulphuric acid, and in many substances in the manufacture of which this acid is used (*v.* H. A. Smith, *P. M.* [4] 44, 370).

*Preparation.*—On the large scale by heating to redness, out of contact with air, arsenical iron or arsenical pyrites; arsenic sublimes; iron, or ferrous sulphide, remains. Prepared in small quantities at a time by heating  $\text{As}_2\text{O}_3$  with powdered charcoal, or with 'black flux,' in crucibles covered with conical iron caps. Also by heating  $\text{As}_2\text{S}_3$  with charcoal, an alkaline carbonate, and KCN. Purified by resublimation after mixing with powdered charcoal; or by heating with a little I (Ludwig, *Ar. Ph.* [2] 97, 23); or by boiling with moderately conc.  $\text{K}_2\text{CrO}_4$  aq. acidified with  $\text{H}_2\text{SO}_4$  (Böttger, *J. pr.* [2] 2, 131). Arsenic was first prepared from arsenious acid in 1694 by Schröder; its chemical nature was further investigated by Brand (1733), Macquer (1746), Margot (1773), and others. Scheele discovered arsenic acid and arsenuretted hydrogen in 1775.

*Properties.*—Very brittle, steel grey, lustrous; crystallises by sublimation in hexagonal rhombohedra isomorphous with Sb and Te;  $a:c=1:1.4025$ ,  $\angle=3.5^\circ$ . When As is sublimed in a rapid H stream in a glass tube the sublimate nearest the heated part of the tube consists chiefly of rhombohedra, that farther from the hottest part but still on a warm portion of the tube (210°-220°) of black amorphous As, while the coolest part of the tube is filled with yellow fumes which condense to grey crystals (Bettendorff, *A.* 141, 110). Black amorphous As is also obtained by condensing As vapour at a fairly high temperature; by decomposing As compounds by heating in glass tubes to

moderately high temperatures (*e.g.*  $\text{AsH}_3$ ), or by heating with reducing agents (*e.g.*  $\text{As}_2\text{O}_3$  with C); or by reduction of As compounds in the wet way (Engel, *C. R.* 96, 497). As can be obtained in regular octahedra by heating a mixture of much H with a little  $\text{AsH}_3$  (Cooke, *Am. S.* [2] 31, 91). Amorphous As is changed to crystalline by heating for some time at 310° (Engel, *C. R.* 96, 1314); by heating to 358°-360° (Bettendorff, *A.* 144, 110). Amorphous As when subjected to a pressure of 6500 atmospheres acquires metallic lustre and its S.G. increases (Spring, *B.* 16, 326). The vapour of As is citron-yellow (Le Roux, *C. R.* 51, 171). The spectrum of As shows lines in the orange (6169.5), yellow, and green (5331) (Thalen, *A. Ch.* [4] 18, 244); also many more refrangible lines (*v.* Hartley, *T.* 1884, 124). As combines with Cl and O with production of heat;  $[\text{As}, \text{Cl}] = 71,390$ ;  $[\text{As}^2, \text{O}] = 154,670$ ;  $[\text{As}^2, \text{O}, \text{Aq}] = 147,120$ ;  $[\text{As}^2, \text{O}] = 219,380$ ;  $[\text{As}^2, \text{O}^2, \text{Aq}] = 225,380$  (Thomsen). As volatilises at a dark red heat without previous fusion at ordinary pressures. The molecule of As is tetratomic ( $\text{As}_4$ ); the atom is trivalent in gaseous molecules ( $\text{AsH}_3$ ,  $\text{AsCl}_3$ , &c.). The atomic weight has been determined (1) by analysing, and determining V.D. of, various gaseous compounds,  $\text{AsH}_3$ ,  $\text{AsCl}_3$ ,  $\text{AsI}_3$ ,  $\text{As}_2\text{O}_3$ , &c.; (2) by determining S.H. of As; (3) by comparing isomorphous compounds of As, Sb, and Bi, arsenates with phosphates and vanadates, &c. (Wallace, *P. M.* [4] 18, 279; Dumas, *A. Ch.* [3] 55, 174; Kessler, *P.* 95, 204).

As is insoluble in alcohol and ether, but is said to be dissolved by certain oils. It oxidises fairly rapidly in air at ordinary temperatures; heated in air, it burns to  $\text{As}_2\text{O}_3$  with a bluish flame; is oxidised by nitric and sulphuric acids, and by fusion with alkalis. As forms two series of compounds, of which  $\text{As}_2\text{O}_3$  and  $\text{As}_2\text{O}_5$  are representatives.

In many of its physical properties As is metallic, but in its chemical relations it is decidedly non-metallic or negative. Exhibits allotropy; oxides are acid-forming (*v.* ARSENIC, OXIDES OF); also ARSENIC, ACIDS OF; at the same time  $\text{As}_2\text{O}_3$  appears to react with  $\text{SO}_2$  to form a salt, and with  $\text{KH}_2\text{C}_2\text{H}_3\text{O}_6$  to form a compound analogous with tartar emetic, and with conc.  $\text{HClAq}$  to form  $\text{AsCl}_3$  (*v.* ARSENIOUS OXIDE, under ARSENIC, OXIDES OF). Arsenious acid is unknown, and an aqueous solution of the oxide behaves towards alkalis as a very feeble salt-forming compound; but arsenic acid is as strong an acid as phosphoric, their relative affinities are nearly equal (*v.* AFFINITY, p. 67). The haloid compounds of As do not show any marked tendencies to form double salts. The hydride  $\text{AsH}_3$  does not combine with acids, as  $\text{NH}_3$  and  $\text{PH}_3$  do; but at the same time compounds belonging to the form  $\text{AsR}_3\text{X}$ , where R is an alcoholic radicle  $\text{C}_2\text{H}_5$ , &c., and X is a halogen or even OH, are known (*v.* ARSENIC COMPOUNDS, ORGANIC). For a fuller discussion of the chemical relations of arsenic *v.* arts. BISMUTH, CHEMICAL RELATIONS OF; and NITROGEN GROUP OF ELEMENTS.

*Reactions.*—1. *Hydrochloric acid*, no action in absence of air; in presence of air a little  $\text{AsCl}_3$  is formed.—2. *Nitric acid* and *aqua regia* react with production of much heat; oxides of N,

$\text{As}_2\text{O}_3$ , and  $\text{H}_3\text{AsO}_3$ , are formed.—3. Hot. conc. sulphuric acid evolves  $\text{SO}_2$ , and forms  $\text{As}_2\text{O}_3$ .—4. Molten potash or soda produces an arsenite and  $\text{H}_2$ .—5. Molten nitre or potassium chlorate produces potassium arsenate; the action is more or less explosive.—6. Solution of sulphur dioxide reacts, when heated with As in a closed tube to  $200^\circ$ , to produce  $\text{As}_2\text{O}_3$ , S, and  $\text{H}_2\text{SO}_4$ , but no sulphide of As (Geitner, *J.* 1861, 143).—7. Ammonia solution is without action on As.

**Combinations.**—1. With nascent hydrogen  $\text{AsH}_3$  and  $\text{AsH}$  are formed (*q. v.*).—2. With chlorine, bromine, or iodine,  $\text{AsCl}_3$ ,  $\text{AsBr}_3$ , or  $\text{AsI}_3$  (*q. v.*) is produced.—3. With fluorine (action of  $\text{HF}$  on  $\text{As}_2\text{O}_3$ )  $\text{AsF}_3$  is formed (*q. v.*).—4. With oxygen As combines to form  $\text{As}_2\text{O}_3$  (*q. v.*);  $\text{As}_2\text{O}_3$  (*q. v.*) is produced by heating one of its hydrates.—5. The sulphides  $\text{As}_2\text{S}_3$  and  $\text{As}_2\text{S}_5$ , and  $\text{As}_2\text{S}_4$  (*q. v.*) are produced by heating together arsenic and sulphur; the sulphide  $\text{As}_2\text{S}_3$  is, however, best obtained by decomposing solutions of alkaline sulpharsenates by acid.—6. Tellurium combines with arsenic to form  $\text{As}_2\text{Te}_2$  and  $\text{As}_2\text{Te}_3$ , when the two elements are melted together in the required proportions (Oppenheim, *J. pr.* 71, 266).—7. When arsenic is melted with sulphur and selenium in the proportions represented by the formulae  $\text{As}_2\text{SeS}$  and  $\text{As}_2\text{SeS}_2$ , two bodies having the compositions indicated are obtained. The first is a lustrous red semi-transparent mass from which the whole of the Se separates out after some days. This body is easily soluble (when powdered) in  $\text{NH}_4\text{HSa}$ . The body  $\text{As}_2\text{SeS}_2$  is a crystalline opaque solid which may be distilled unchanged; it is less easily soluble in  $\text{NH}_4\text{HSa}$  than  $\text{As}_2\text{SeS}$  (*v. Gerichten*, *B.* 7, 29).—8. Arsenic appears to be incapable of combining with phosphorus directly (older experiments by Landergerbe (*S.* 60, 184) probably yielded only a mixture of P and As); but if  $\text{AsH}_3$  is led into  $\text{PCl}_3$ , or  $\text{PH}_3$  into  $\text{AsCl}_3$ , a red-brown solid is obtained (after drying it appears as a darker powder without lustre) which is insoluble in alcohol, ether, and  $\text{CHCl}_3$ , but fairly soluble in  $\text{CS}_2$ . This solid is  $\text{PAs}$ ; it is changed by water into  $\text{P}_2\text{As}_2\text{O}_5$  with which chlorine reacts to produce  $\text{AsCl}_3$  and  $\text{POCl}_3$ . The compound  $\text{PAs}$  is rapidly oxidised by concentrated  $\text{HNO}_3$ , less rapidly by dilute  $\text{HNO}_3$ , giving  $\text{H}_3\text{AsO}_4$  and  $\text{H}_3\text{PO}_4$ ; solutions of  $\text{COH}$ ,  $\text{NH}_4\text{OH}$ , or  $\text{Ba(OH)}_2$ , easily decompose  $\text{PAs}$  rapidly (when warm) producing  $\text{PH}_3$ ,  $\text{AsH}_3$ ,  $\text{H}_3\text{PO}_4$ ,  $\text{H}_3\text{AsO}_3$ , and As. Heated in air  $\text{PAs}$  burns to  $\text{As}_2\text{O}_3$  and  $\text{P}_2\text{O}_5$ ; heated in absence of air, or a  $\text{CO}_2$ , phosphorus sublimes and then arsenic. The reactions of  $\text{P}_2\text{As}_2\text{O}_5$  are very similar to those of  $\text{PAs}$  (*v. Janowsky*, *B.* 6, 216; 8, 1636).—Arsenic forms alloys with many metals. Some of these are produced by very strongly compressing the constituents (Spring, *B.* 16, 324). These alloys are generally brittle, they are only partially, in many cases not at all, separated into their constituents by the action of heat out of contact with air; they are generally oxidised to arsenates, and oxides of the metals, by fusion with nitre; fused with alkaline carbonates and sulphur, thio-arsenite or thio-arsenate of the alkaline metal is generally produced, and the metals formerly alloyed with the arsenic are completely separated as sulphides. Arsenides of heavy metals are scarcely if at all attacked by nitric acid or aqua regia. Many alloys of arsenic are

definite compounds; several of them occur native as minerals (*v. Winkler*, *J. pr.* 91, 193; Sénarmont, *A. Ch.* 80, 221; Rammelsberg, *P.* 128, 441). The alloys with cobalt, which are brittle and iron-grey in colour, are formed, with production of heat, by melting the elements together. CoAs occurs native as *Smaltine*; it always contains more or less iron and nickel replacing part of the arsenic.  $\text{Co}_2\text{As}_3$ , generally containing more or less iron, also occurs native as *Skutterudite*, or *Modumite*. Arsenic alloys with copper to form white solids which tarnish in the air. According to Lippert (*J. pr.* 81, 168) the grey deposit obtained by heating copper in an HCl solution of arsenious oxide is  $\text{Cu}_3\text{As}_2$ ; when this body is heated in hydrogen  $\text{Cu}_3\text{As}$  remains. The compounds  $\text{Cu}_3\text{As}$ ,  $\text{Cu}_2\text{As}$ , and  $\text{Cu}_4\text{As}$ , occur native as *Domeykite*, *Algodonite*, and *Darwinite*, respectively. The alloys of arsenic and iron are brittle solids formed by melting the elements together;  $\text{FeAs}_2$  and  $\text{Fe}_2\text{As}_3$  occur native as *Arsenical iron*, sometimes containing Ag, Au, and Cu. Arsenic alloys with lead to form brittle solids. With nickel, arsenic alloys easily;  $\text{Ni}_2\text{As}$  is obtained by melting the elements together. The minerals *Copper-nickel*  $\text{NiAs}$ , and *Cloanthite*  $\text{NiAs}_2$  occur native; they contain varying quantities of Sb, Fe, Pb, Co, and Cu. A lustrous crystalline alloy  $\text{Ni}_3\text{As}$  is obtained by reducing arsenate of nickel by charcoal at a high temperature;  $\text{Ni}_3\text{As}$  is said to be formed when KCN, As, and NiO are fused together (Descamps, *C. R.* 86, 1065). Arsenic also alloys, with production of much heat, with potassium and sodium; the products are decomposed by water with formation of KOH (or NaOH)  $\text{Aq}$ ,  $\text{AsH}_3$ , and As. An alloy of 15 parts tin and 1 part arsenic forms large leaf-like crystals. Arsenic is not much used in technical chemistry; the alloy with lead is employed in making shot. Arsenic appears to form alloys with several other metals, especially Hg (?) Pd and Pt. By strongly compressing (6500 atmos.) As with various metals, Spring (*B.* 16, 326) obtained several well-defined alloys, *e.g.*  $\text{Zn}_3\text{As}_2$ ,  $\text{Cu}_3\text{As}_2$ , &c. &c.

**Detection.**—In dry way. Arsenic heated with slight access of air volatilises with a garlic-like odour (probably due to a little  $\text{As}_2\text{O}_3$ ) and condenses on cooling as a lustrous black deposit, which is easily converted into a white crystalline sublimate ( $\text{As}_2\text{O}_3$ ) by heating in presence of plenty of air. Sulphides or oxides of arsenic, and the salts of arsenious and arsenic acid, yield sublimates of black amorphous arsenic when heated with an alkaline carbonate alone or mixed with charcoal or KCN (*v. Fresenius*, *A.* 49, 301; Rose, *P.* 90, 143). Oxide of arsenic heated with much  $\text{Na}_2\text{C}_2\text{H}_3\text{O}_2$  in a tube closed at one end yields cacodyl oxide, recognised by its foul smell. In wet way. 1. *Arsenious compounds.* (i.) *Sulphuretted hydrogen* passed into a solution of  $\text{As}_2\text{O}_3$ , or an arsenite, acidified with HCl, forms a bright yellow pp. of  $\text{As}_2\text{S}_3$ , soluble in  $\text{NH}_4\text{OH}$ ,  $\text{NH}_4\text{SH}$ , and  $(\text{NH}_4)_2\text{CO}_3$  solutions, and reprecipitated by HCl.  $\text{As}_2\text{S}_3$  is said to be soluble in a considerable quantity of boiling water and in boiling dilute HCl (Odling, *Gay's Hosp. Rep.* [3] 1, 239). (ii.) *Neutral solution of silver nitrate* produces a canary-yellow pp. of  $\text{Ag}_3\text{AsO}_4$ , easily soluble in most acids and in

ammonia. (iii.) *Neutral solution of copper sulphate* precipitates green  $\text{CuHAsO}_4$  (Scheele's green) easily soluble in acids and in ammonia.

(iv.) *Reinsch's test* (*J. pr.* 24, 244). A warm solution of an arsenious compound acidified with HCl deposits a film of arsenic on a piece of bright copper kept in contact with it for some time; this deposit may be oxidised to  $\text{As}_2\text{O}_3$  by heating in air (*v. supra*). The deposit consists of  $\text{As}_2\text{Cu}$ , according to Lippert (*J. pr.* 81, 168). Arsenic compounds may be detected by Reinsch's test, if present in considerable quantity (Werther, *J. pr.* 82, 286), even in small quantity if heated for some time with HCl (Reinsch, *N. J. P.* 16, 135); the HCl used must not be weaker than S.G. 1.1 (Bettendorff, *Z.* [2] 5, 492). According to J. M. Scherer (*Er.* 3, 200) the delicacies of the wet tests are as follows;  $\text{AgNO}_3$  detects  $\frac{1}{200,000}$

part of  $\text{As}$ ,  $\text{CuSO}_4$  detects  $\frac{1}{13,500}$  part,  $\text{H}_2\text{S}$  detects  $\frac{1}{610,000}$  part, and Reinsch's test detects  $\frac{1}{170,000}$  part, or after boiling for  $\frac{1}{4}$  hour  $\frac{1}{250,000}$

part of  $\text{As}$ . (v.) *Marsh's test*. When hydrogen is evolved in contact with an acidified solution of an arsenious compound, whether by the action of zinc (Marsh, *B. J.* 17, 191; 20, 190; 22, 175), magnesium (Roussin, *J.* 1866, 801), or the electric current (Bloxam, *C. J.* 13, 14), arsenic trihydride is evolved; arsenic may be separated by passing the gas through a glass tube heated at one part, or by burning the gas in a limited supply of air and presenting a cold surface of porcelain, or thick platinum (Davy, *J.* 1858, 609), on which the arsenic condenses. The deposit of arsenic is easily soluble in  $\text{HNO}_3$ , S.G. 1.2 to 1.3; the solution contains arsenious acid (which on boiling for some time is changed to arsenic acid), it gives the characteristic yellow pp. of  $\text{Ag}_3\text{AsO}_4$  (*v. supra*); the deposit of arsenic is also easily soluble in aqueous  $\text{NaClO}$  free from  $\text{Cl}$ ; if the deposit is warmed in dry  $\text{H}_2\text{S}$  yellow  $\text{As}_2\text{S}_3$  is produced which is not changed when warmed in a current of dry HCl gas. Arsenious hydride passed into aqueous  $\text{AgNO}_3$  precipitates  $\text{Ag}$ , but the whole of the  $\text{As}$  remains in solution along with  $\text{HNO}_3$  formed in the reaction, and may be detected by filtering and carefully neutralising the filtrate with dilute ammonia, when yellow  $\text{Ag}_3\text{AsO}_4$  is produced. [ $\text{SbH}_3$  precipitates  $\text{Ag}$  from  $\text{AgNO}_3$ , but the whole of the  $\text{Sb}$  is at the same time thrown down; the deposit of  $\text{Sb}$  obtained by heating, or burning,  $\text{SbH}_3$  is insoluble in  $\text{NaClO}$  solution free from  $\text{Cl}$ , and is much less soluble than  $\text{As}$  in  $\text{HNO}_3$  aq. of S.G. 1.2 to 1.3; moreover, the solution in  $\text{HNO}_3$  aq. gives no reaction with  $\text{AgNO}_3$  aq. and ammonia. The reactions of the two gases towards  $\text{AgNO}_3$  solution affords a means for separating them (Husson, *C. R.* 83, 199).] The electrolytic method of preparing  $\text{AsH}_3$  has the advantages (a) of avoiding the use of zinc which generally contains arsenic; (b) of not interfering with the subsequent testing for other metals; (c) of allowing the separation of antimony if present—this is done by adding a little  $\text{H}_2\text{S}$  to the liquid, whereby  $\text{As}_2\text{S}_3$  and  $\text{Sb}_2\text{S}_3$  are formed; the former is easily, the latter not at all, decomposed by the current (Bloxam, *C. J.* 13, 14, 338). The presence of  $\text{HNO}_3$  prevents the formation of  $\text{AsH}_3$  (Blondlot,

*J.* 1863, 681). (vi.) *Bettendorff's test* (*Z.* [2] 5, 492). Stannous chloride in fuming HCl, added to a solution of  $\text{As}_2\text{O}_3$  or  $\text{As}_2\text{S}_3$  in the same acid, precipitates metallic  $\text{As}$  mixed with a little  $\text{SnO}_2$ . This test is said to be extremely delicate; it may be used to detect  $\text{As}$  in presence of  $\text{Sb}$ , also to remove  $\text{As}$  from  $\text{HCl}$  aq. (*v. also* Hager, *J.* 1870, 966). II. *Arsenic compounds*. (i.) *Neutral silver nitrate* precipitates red-brown  $\text{Ag}_3\text{AsO}_4$ , soluble in  $\text{NH}_4\text{OH}$  aq. and in  $\text{HNO}_3$  aq., but less soluble in  $\text{HNO}_3$  aq. than  $\text{Ag}_3\text{AsO}_3$ , so that if  $\text{AgNO}_3$  is mixed with a solution of an arsenite and an arsenate in  $\text{HNO}_3$  aq., and  $\text{NH}_4\text{OH}$  aq. is then added drop by drop,  $\text{Ag}_3\text{AsO}_4$  is precipitated before  $\text{Ag}_3\text{AsO}_3$ ; a solution of arsenic acid in nitric acid is precipitated by  $\text{AgNO}_3$  if a few drops of a concentrated solution of an alkaline acetate are added (Avery, *Am. S.* [2] 47, 25). (ii.) *Neutral copper sulphate* precipitates bluish green  $\text{CuHAsO}_4$ , soluble in  $\text{HNO}_3$  aq. and in  $\text{NH}_4\text{OH}$  aq. (iii.) *An alkaline solution of magnesium sulphate*, containing enough  $\text{NH}_4\text{Cl}$  to prevent precipitation of magnesia, precipitates white  $\text{Mg}(\text{NH}_4)\text{AsO}_4$ ; delicacy 1 part of  $\text{As}$  in 56,000 (Lovel, *B. J.* 28, 130) (*cf. Estimation of Arsenic*). (iv.) *Ammonium molybdate* in excess precipitates bright yellow arseno-molybdate of ammonium from warm (not cold) solutions of arsenates containing  $\text{HNO}_3$ . (v.) *Sulphuretted hydrogen* slowly reduces arsenic to arsenious acid and then (in presence of HCl) precipitates yellow  $\text{As}_2\text{S}_3$  mixed with  $\text{S}$ . (vi.) *Marsh's test*. Arsenic compounds in solution are reduced to  $\text{AsH}_3$  by hydrogen evolved in contact with the solution; the reduction takes place under the same conditions as, but more slowly than, the reduction of arsenious compounds (*v. supra*).

Arsenic may be reduced to arsenous compounds by such deoxidising agents as sulphurous or phosphorous acid; the reverse change may be accomplished by heating with  $\text{HNO}_3$  aq.,  $\text{HCl}$  aq. and  $\text{KClO}_4$ , &c.

*Detection in cases of poisoning*.—Arsenious oxide or white arsenic is the usual form in which the poison is administered. Because of the insolubility of this compound, small solid particles of it may sometimes be picked out of the food or contents of the intestine; these should be tested by reduction to metallic arsenic, &c., in the dry way. The poison is, however, usually mixed with large quantities of organic matter which must be removed or destroyed, after which the arsenic may be ppd. as  $\text{As}_2\text{S}_3$  by long-continued passage of  $\text{H}_2\text{S}$ , the pp. may then be dissolved in warm  $\text{HCl}$  aq. with a crystal of  $\text{KClO}_4$ , free chlorine removed by warming, or the pp. may be dissolved in warm  $\text{H}_2\text{SO}_4$  aq. and Reinsch's, or better Marsh's, test used for detecting the arsenic in solution. The organic matter may be removed by diffusion (Graham); or it may be destroyed by (a) treatment with warm concentrated  $\text{H}_2\text{SO}_4$  aq., (b) warming with  $\text{HCl}$  aq. and crystals of  $\text{KClO}_4$ , added from time to time, (c) warming with  $\text{HCl}$  aq. and a little  $\text{HNO}_3$  aq., (d) passing  $\text{Cl}$  into the liquid instead of adding  $\text{KClO}_4$ , (e) heating with  $\text{HNO}_3$  aq. till the residue is semi-pasty and yellow, adding  $\text{NaOH}$  aq. till the acid is neutralised, mixing with powdered  $\text{Na}_2\text{CO}_3$  and a little  $\text{NaNO}_3$ , drying in a crucible and gradually heating until the mass fuses (Wöhler; *v. also* Meyer, *A.* 66, 287). All re-

agents used must be carefully freed from arsenic; a blank experiment should be conducted with the reagents alone.<sup>1</sup> (Buiz a. Schulz find that certain parts of the animal organism reduce  $\text{As}_2\text{O}_3$  and also oxidise  $\text{As}_2\text{O}_3$ ; they think that the poisonous effects of  $\text{As}_2\text{O}_3$  are due to rapid de-oxidation and reoxidation, v. B. 12, 2199; 14, 2400; 15, 1388.)

*Estimation.*—I. *Gravimetric methods.*

(i.) As magnesium-ammonium arsenate. Solution of  $\text{MgSO}_4$  is mixed with excess of  $\text{NH}_4\text{OH}$  and allowed to stand for 12 hours; this liquid is added to the solution containing arsenic acid to which an excess of  $\text{NH}_4\text{OH}$  has previously been added. After some time the pp. is collected on a weighed filter, washed with ammonia-water, and either (a) dried *in vacuo* over  $\text{H}_2\text{SO}_4$ , when it has the composition  $\text{Mg}(\text{NH}_4)_2\text{As}_2\text{O}_7 \cdot 6\text{H}_2\text{O}$ , or (b) dried at  $100^\circ$  to  $110^\circ$  whereby  $2(\text{Mg}(\text{NH}_4)_2\text{As}_2\text{O}_7) \cdot \text{H}_2\text{O}$  is produced, or (c) strongly heated over a Bunsen lamp (temperature being gradually raised) whereby  $\text{Mg}(\text{NH}_4)_2\text{As}_2\text{O}_7$  is formed. Method c is recommended by Puller (Fr. 10, 41), who states that the best means of converting  $\text{As}_2\text{S}_3$  into arsenic acid is treatment with red fuming  $\text{HNO}_3$  (v. also Rammelsberg, B. 7, 544; Wood, Am. S. [3] 6, 368; Macivor, C. M. 32, 283).—(ii.) As arsenious sulphide. Arsenates are reduced to arsenites by  $\text{SO}_2$  solution; the arsenious solution is acidified with  $\text{HCl}$  and  $\text{As}_2\text{S}_3$  is ppd. by long-continued passage of  $\text{H}_2\text{S}$ ; the pp. is washed with  $\text{H}_2\text{S}$  to remove any S which it may contain, collected on a weighed filter, and dried at  $100^\circ$ – $110^\circ$  (Puller, Fr. 10, 41).—(iii.) As triaryl pyroarsenate. Uranic acetate in presence of ammonium salts pps. ammonium-aryl arsenate  $\text{NH}_4(\text{UO}_2)_2\text{AsO}_4 + \text{Aq}$ , insoluble in water and acetic acid, but soluble in mineral acids. When this pp. is washed, dried, and gradually heated to bright redness, the pyroarsenate  $(\text{UO}_2)_2\text{As}_2\text{O}_7$  is obtained. This method is recommended by Puller (l.c.);  $\text{As}_2\text{S}_3$  may be dissolved in  $\text{HCl}$  and  $\text{KClO}_4$  and the As ppd. after adding  $\text{NH}_4\text{C}_2\text{H}_3\text{O}_2$  and  $\text{H}_2\text{C}_2\text{H}_3\text{O}_2$  aq.

II. *Volumetric methods.*—(i.) By iodine. Arsenious is converted into arsenic acid, by iodine in presence of alkali; a solution of  $\text{NaHCO}_3$  saturated in the cold and used in excess is the best alkali (Waitz, Fr. 10, 158).—(ii.) By potassium dichromate. Arsenites are converted into arsenates by the action of  $\text{K}_2\text{Cr}_2\text{O}_7$  in acid solutions; the residual  $\text{K}_2\text{Cr}_2\text{O}_7$  is determined by a solution of  $\text{FeSO}_4$ ; excess of  $\text{HCl}$  should be avoided (Kessler, Fr. 10, 205).—(iii.) By potassium permanganate. Arsenites are oxidised to arsenates by  $\text{Mn}_2\text{O}_3$  in solutions containing  $\text{H}_2\text{SO}_4$ ; an excess of  $\text{KMnO}_4$  is added, and the residual  $\text{Mn}_2\text{O}_3$  is determined by  $\text{FeSO}_4$  solution (Waitz, l.c.).

Minute attention to detailed precautions must be observed in testing for arsenic in poisonous cases. These will be found in the following memoirs and notes:—Marsh, P. J. 17, 191; 20, 190; 22, 175; Regnier, A. Ch. [3] 2, 169; Fresenius a. v. Babo, A. 49, 387; Regnier, A. 69, 364; Schneider, P. 85, 433; Fyfe, P. M. 3; Zenger, Fr. 1, 391; Wöhler, a. v. Siebold, Das gerichtl. Verfahren bei einer Arsenit-Vergiftung (1847); v. S. Ausmittelung der Gifte (English ed. On Poisons) 1850; Dumas, Prüfung chem. Gifte (1867); Taylor's Legal Jurisprudence; Taylor's On Poisons.

*References.*—Besides the papers referred to in the article, the following older memoirs on arsenic and its compounds may be consulted:—Scheele, Opus. 2, 28; Bergmann, Opus. 2, 272; Buchholz, S. 15, 537; Laugier, A. Ch. 85, 26; Fischer, S. 6, 236; 12, 155; 39, 364; Thomson, S. 17, 422; 29, 430; Berzelius, A. Ch. [2] 5, 179; 11, 225; S. 34, 46; P. 7, 1, 137; Gehlen, S. 15, 501; Gay Lussac, A. Ch. [2] 3, 186; Pfaff, S. 45, 95; Buchner, S. 45, 419; Soubeiran, P. 19, 991; Mitscherlich, A. Ch. [2] 19.

**Arsenic acid and Arsenates v. ARSENIC, ACIDS OF.**

**Arsenic, acids of.**—(In connection with these compounds v. arts. ACIDS; ACIDS, BASICITY OF; HYDROXIDES.) Arsenious oxide,  $\text{As}_2\text{O}_3$ , dissolves in alkalis, forming salts from which other arsenites may be obtained; no hydrate of  $\text{As}_2\text{O}_3$  is, however, known. The heat of solution of the oxide is negative;  $[\text{As}^{+3}\text{O}_3, \text{Aq}] = -15,100$ . Arsenic oxide,  $\text{As}_2\text{O}_5$ , dissolves in water with formation of the hydrate  $\text{H}_2\text{AsO}_4$ , which crystallises from concentrated solutions as  $2\text{H}_2\text{AsO}_4 \cdot \text{H}_2\text{O}$ ; these crystals heated to  $100^\circ$  lose water, and arsenic acid,  $\text{H}_2\text{AsO}_4$ , remains. By the action of heat on this acid, two other acids are produced, viz. at  $140^\circ$ – $180^\circ$  pyroarsenic acid  $\text{H}_2\text{As}_2\text{O}_7$ , and at  $200^\circ$  metarsenic acid  $\text{HASO}_3$ ; these acids dissolve in water with reproduction of  $\text{H}_2\text{AsO}_4$ . Each arsenic acid yields a series of salts; the arsenates (or ortho-arsenates), divisible into three classes of the forms  $\text{MH}_2\text{AsO}_4$ ,  $\text{M}_2\text{HASO}_4$ , and  $\text{M}_3\text{AsO}_4$ ; the pyroarsenates  $\text{M}_2\text{As}_2\text{O}_7$ ; and the metarsenates  $\text{MASO}_3$ . The pyro- and metarsenates have not been much investigated, they appear to exist only as solids and to yield arsenates when brought into contact with water. Thomsen's thermal examination of the behaviour of aqueous solutions of the two oxides of arsenic towards soda shows that these solutions differ much as regards reactions and hence also as regards composition. In each case the thermal behaviour of the oxide of arsenic is compared with that of the corresponding oxide of phosphorus (the formula  $\text{As}_2\text{O}_3$  is used as being directly comparable with  $\text{P}_2\text{O}_5$ ).

$x[\text{As}^{+3}\text{O}_3\text{Aq}, x\text{NaOH}\text{Aq}] \text{ diff. } [\text{P}^{+5}\text{O}_5\text{Aq}, x\text{NaOH}\text{Aq}]$ .

1	7,300	6,500	13,700	14,800
2	13,800	1,200	400	28,500
3	15,000	600		28,900
6	15,600			
$x[\text{As}^{+5}\text{O}_5\text{Aq}, x\text{NaOH}\text{Aq}] \text{ diff. } [\text{P}^{+5}\text{O}_5\text{Aq}, x\text{NaOH}\text{Aq}]$ .				
1	14,800	12,300	12,600	15,000
2	27,100	6,900	8,400	27,600
3	34,000	1,300	1,400	36,000
6	35,300			37,400

The mean thermal value of the reaction which occurs when one formula-weight of soda is added to an acid is 13,500; this value is reached when  $2\text{NaOH}\text{Aq}$  is added to  $\text{As}_2\text{O}_3\text{Aq}$ , but a little more heat is produced when a third formula-weight of soda is added. The values when baryta solution is used are  $[\text{As}^{+3}\text{O}_3\text{Aq}, \text{BaO}\text{Aq}] = 14,000$ ;  $[\text{As}^{+5}\text{O}_5\text{Aq}, 2\text{BaO}\text{Aq}] = 15,600$ . It seems probable that the soda reacts with

water and arsenious oxide, not with arsenious acid, to produce an arsenite  $\text{NaAsO}_2 \cdot \text{HAsO}_2$ , analogous to potassium arsenite, and that addition of more soda changes this either into the normal, or some other, arsenite.

**I. ARSENIOS ACID AND ARSENITES** (Pasteur, *A.* 68, 308; Filhol, *A.* 68, 308; Kühn, *Ar. Ph.* [2] 69, 267; Streng, *A.* 120, 238; Stein, *A.* 74, 218; Reynoso, *C. R.* 81, 68; Girard, *C. R.* 84, 918; 36, 973; Bloxam, *C. J.* 15, 281). No arsenious acid has been obtained in separate form; but an aqueous solution of the oxide  $\text{As}_2\text{O}_3$  reacts with bases to form unstable salts the compositions of which may be well represented by regarding them as derived from one or other of the three hypothetical arsenious acids,  $\text{H}_3\text{AsO}_3 (= \text{As}(\text{OH})_3)$ ,  $\text{HAsO}_2 (= \text{AsO}(\text{OH}))$ ,  $\text{H}_2\text{AsO}_2 (= \text{As}_2\text{O}(\text{OH}))$ . The arsenites as a class are very easily decomposed; the ammonium salt gives off ammonia at ordinary temperatures and pressures, its aqueous solution yields pure  $\text{As}_2\text{O}_3$  on evaporation; the potassium and sodium salts are decomposed in solution by carbon dioxide with separation of  $\text{As}_2\text{O}_3$ .  $\text{CaO}$ ,  $\text{BaO}$ , and  $\text{SrO}$  dissolve when boiled with water and  $\text{As}_2\text{O}_3$ , addition of lime-baryta- or strontia-water precipitates arsenites insoluble in water, but soluble in acids and in ammonia. Solutions of arsenites of metals which form sulphides soluble in water are decomposed by  $\text{H}_2\text{S}$  with precipitation of  $\text{As}_2\text{S}_3$ ; if the metal of the arsenite forms a sulphide insoluble in water then  $\text{H}_2\text{S}$  precipitates this sulphide along with  $\text{As}_2\text{S}_3$ . Many arsenites are not, however, decomposed by metals even when the oxide of the metal of the arsenite is insoluble in potash. Insoluble arsenites are obtained by adding a soluble salt of the metal to a solution of K or Na arsenite. All arsenites, with the exception of those of the alkali metals, are partially or wholly insoluble in water; when formed they usually retain some arsenious oxide, so that it is difficult, and sometimes impossible, to obtain definite compounds of fixed composition. Most arsenites are decomposed by heat with formation of an arsenate and arsenic; heated with carbon, or with carbon and borax, the whole of the arsenic is usually separated in the metallic state. Heated with ammonium chloride, most arsenites yield  $\text{AsCl}_3$  and chloride of the metal of the arsenite. Solutions of the alkaline arsenites exposed to the air absorb oxygen and produce arsenates (Fresenius, *J.* 1855, 382).

**Arsenites. Ammonium arsenites**  $\text{NH}_4\text{AsO}_2$  (Pasteur, Bloxam);  $(\text{NH}_4)_2\text{As}_2\text{O}_5$  (Stein). By dissolving  $\text{As}_2\text{O}_3$  in conc. aqueous  $\text{NH}_3$ ; white lustrous prisms, very soluble in water.

**Barium arsenites**  $\text{Ba}(\text{AsO}_2)_2$ ; white gelatinous pp. by adding  $\text{BaCl}_2$  to  $\text{KAsO}_2$  (Filhol).  $\text{BaH}_2(\text{AsO}_2)_2$ ; by mixing  $\text{BaCl}_2$  with  $\text{As}_2\text{O}_3$  and  $\text{NH}_4\text{AsO}_2$  (Bloxam).  $\text{Ba}_3\text{As}_2\text{O}_7 \cdot 4\text{H}_2\text{O}$ ; by dissolving  $\text{As}_2\text{O}_3$  in  $\text{BaO}$  (Stein).

**Calcium arsenites.** Solutions of the various potassium arsenites mixed with  $\text{CaCl}_2$  yield pps. of varying composition (Filhol, Stein). A boiling solution of  $\text{As}_2\text{O}_3$  added to  $\text{CaO}$  precipitates  $\text{Ca}_3(\text{AsO}_2)_4$  (Kühn).  $\text{CaCl}_2$  mixed with  $\text{As}_2\text{O}_3$  and  $\text{NH}_4\text{AsO}_2$  precipitates  $\text{Ca}(\text{AsO}_2)_2$  (Simon, *P.* 40, 417).  $\text{As}_2\text{O}_3$  with excess of  $\text{CaO}$  precipitates  $\text{Ca}_3\text{As}_2\text{O}_7$  (Stein).

**Cobalt arsenite.**  $\text{Co}_2\text{H}_6(\text{AsO}_2)_4 \cdot \text{H}_2\text{O}$ ; rose-red

pp. produced by reaction of  $\text{KAsO}_2$  with  $\text{CoCl}_2$  in presence of  $\text{NH}_4\text{Cl}$ .

**Copper arsenites.**  $\text{CuSO}_4$  +  $\text{KAsO}_2$  or ammoniacal  $\text{CuSO}_4$  +  $\text{As}_2\text{O}_3$  yields a light green pp. (Scheele's green) of  $\text{CuHAsO}_2$ ; soluble in  $\text{NH}_4\text{AsO}_2$  with formation of  $\text{H}_2\text{AsO}_2$  and  $\text{Cu}_2\text{O}$ ; soluble in  $\text{KOH}$  with formation of  $\text{K}_2\text{AsO}_4$  and  $\text{Cu}_2\text{O}$ , which precipitates; when heated,  $\text{CuHAsO}_2$  evolves  $\text{As}$  and  $\text{H}_2\text{O}$ , and a mixture of  $\text{CuO}$  and copper arsenide remains. By digesting  $\text{CuCO}_3$  with  $\text{H}_2\text{O}$  and  $\text{As}_2\text{O}_3$  and evaporating the solution, a yellow-green salt, probably  $\text{Cu}(\text{AsO}_2)_2$ , is produced.

**Iron arsenites.** Ferrous arsenite  $\text{Fe}_2\text{AsO}_4$  is a greenish-white pp., soluble in  $\text{NH}_4\text{AsO}_2$ , obtained by mixing  $\text{FeSO}_4$  with  $\text{As}_2\text{O}_3$  and a little  $\text{NH}_4\text{AsO}_2$ . Various ferric arsenites appear to exist. Freshly precipitated  $\text{Fe}_2(\text{OH})_6$  digested with conc.  $\text{As}_2\text{O}_3$  containing not more than  $\frac{1}{2}$  as much  $\text{As}_2\text{O}_3$  as there is  $\text{Fe}_2(\text{OH})_6$ , completely converts all the  $\text{As}_2\text{O}_3$  into an insoluble salt (Bunsen); with less  $\text{Fe}_2(\text{OH})_6$ , the whole of the  $\text{As}_2\text{O}_3$  is not removed from solution, a basic salt,  $\text{FeAsO}_4 \cdot \text{Fe}_2\text{O}_3$ , is produced from which water removes some  $\text{As}_2\text{O}_3$ . A basic salt (rusty-red, hard, soluble in  $\text{NaOH}$ ),  $2\text{FeAsO}_4 \cdot \text{Fe}_2\text{O}_3 \cdot 7\text{H}_2\text{O}$ , is produced (a) by adding  $\text{Fe}_2\text{SO}_4$  or  $\text{Fe}_2\text{Cl}_2$  to  $\text{KAsO}_2$ , (b) by oxidising  $\text{FeSO}_4$  by *aqua regia*, neutralising by  $\text{NH}_4\text{AsO}_2$ , adding a saturated solution of  $\text{As}_2\text{O}_3$  in  $\text{NaOH}$ , and allowing to stand for twelve hours. Another salt,  $2\text{FeAsO}_4 \cdot \text{Fe}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ , is obtained, as an ochre-yellow pp. drying to a brown mass, on mixing  $\text{As}_2\text{O}_3$  or  $\text{KAsO}_2$  with  $\text{Fe}(\text{C}_2\text{H}_3\text{O}_2)_3$ ; water withdraws part of the acid from this salt; it is decomposed by heat, losing all its arsenious acid (Simon); only a part of its acid (Bunsen; v. also Grimaux, *Bl.* [2] 42, 211).

**Lead arsenites.**  $\text{Pb}(\text{AsO}_2)_2$  is a white pp. (Filhol), melting to a yellow glass (Berzelius), obtained by adding  $\text{KAsO}_2$  to  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$ . Other salts are known:  $\text{Pb}_2\text{As}_2\text{O}_7$  (?) by precipitating  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$  by  $\text{As}_2\text{O}_3$  and  $\text{NH}_4\text{AsO}_2$  (Filhol, Bloxam);  $\text{Pb}_3(\text{AsO}_2)_4$ , by precipitating  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$  by (a) boiling  $\text{As}_2\text{O}_3$  (Kühn, Bloxam), or (b)  $\text{As}_2\text{O}_3$  in  $\text{NaOH}$  (Streng, *A.* 129, 238).

**Magnesium arsenites.** A solution of  $\text{As}_2\text{O}_3$  in excess of  $\text{NH}_4\text{AsO}_2$  mixed with  $\text{MgSO}_4$  with  $\text{NH}_4\text{Cl}$  gives a pp. which is  $\text{Mg}_2(\text{AsO}_2)_4$  (Stein),  $\text{MgHAsO}_4 \cdot \text{H}_2\text{O}$  (Bloxam); heated to above  $250^\circ$   $\text{Mg}_2\text{As}_2\text{O}_7$  remains. Other salts appear to exist, but their composition is vague and uncertain (v. Filhol, l.c.).

**Manganese arsenite.**  $\text{Mn}_2\text{H}_6(\text{AsO}_2)_4 \cdot 2\text{H}_2\text{O}$  is a light rose-red pp. obtained by adding  $\text{NH}_4\text{AsO}_2$  to  $\text{MnSO}_4$ .

**Mercury arsenites.** Composition undecided.  $\text{Hg}_2\text{NO}_2$  mixed with  $\text{As}_2\text{O}_3$  gives a white pp. soluble in  $\text{KAsO}_2$ ; if excess of  $\text{KOH}$  present  $\text{Hg}$  is precipitated. An arsenite of mercury seems to be formed by mixing  $\text{HgNO}_2$  with  $\text{KAsO}_2$ , or by digesting  $\text{As}_2\text{O}_3$  with  $\text{Hg}$ .

**Nickel arsenite.**  $\text{Ni}_2\text{H}_6(\text{AsO}_2)_4 \cdot \text{H}_2\text{O}$  is obtained as a greenish-white pp. on adding  $\text{KAsO}_2$  to  $\text{NiCl}_2$  containing much  $\text{NH}_4\text{Cl}$ ; heated in air, this salt loses  $\text{H}_2\text{O}$ , then  $\text{As}_2\text{O}_3$ , and yellow infusible  $\text{Ni}_3(\text{AsO}_2)_4$  remains.

**Potassium arsenites.** The acid salt  $\text{KAsO}_2 \cdot \text{HAsO}_2 \cdot \text{H}_2\text{O}$  is produced by adding alcohol

to a solution of much  $\text{As}_2\text{O}_3$  in  $\text{KOH}$  (Pasteur, Bloxam). By digesting this salt with  $\text{K}_2\text{CO}_3$  the neutral salt  $\text{KAsO}_3$  is produced (Pasteur, Filhol); by treating this with  $\text{KOH}$  and precipitating by alcohol the salt  $\text{K}_2\text{As}_2\text{O}_7$  is formed (Bloxam). Two double salts,  $\text{KAsO}_3 \cdot \text{HAsO}_3 \cdot \text{AsOI}$  and  $\text{K}_2\text{H}_3\text{As}_3\text{O}_7 \cdot 2\text{KI}$  are described by Emmet (*Am. S.* [2] 18, 583), and Harms (*A.* 91, 371), obtained by adding  $\text{KIAg}$  to  $\text{As}_2\text{O}_3$  or  $\text{KIAg}$  to  $\text{KAsO}_3$  containing so much  $\text{H}_2\text{C}_2\text{H}_3\text{O}_2$  that no brown colour is produced with turmeric paper.

**Silver arsenites.**  $\text{Ag}_3\text{AsO}_3$ , a yellow pp. obtained by adding  $\text{As}_2\text{O}_3$  neutralised by  $\text{NH}_4\text{Aq}$  to  $\text{AgNO}_3$  (Kühn, Filhol, Bloxam); soluble in  $\text{HNO}_3$ ,  $\text{H}_2\text{C}_2\text{H}_3\text{O}_2$ ,  $\text{NH}_4\text{Aq}$ , and solutions of ammonium salts, also in  $\text{KOH}$  or  $\text{KOH}$  solutions are not precipitated by  $\text{KCl}$  or  $\text{KBr}$ , but dissolve freshly prepared  $\text{AgCl}$ . Heated alone or with alkalis it is decomposed;

$4\text{Ag}_3\text{AsO}_3 = \text{Ag}_2\text{O} + 2\text{Ag} + 2\text{Ag}_3\text{AsO}_4 + \text{As}_2\text{O}_3$  (Wöhler, *A.* 101, 363). Other silver arsenites are described by Harms (*l.c.*).

**Sodium arsenites.** None obtained pure; seem to be all very soluble in water (Pasteur, Filhol, Bloxam).

**Strontium arsenite.**  $\text{Sr}(\text{AsO}_3)_2 \cdot 4\text{H}_2\text{O}$ . By mixing  $\text{SrCl}_2$  with  $\text{KAsO}_3$  and allowing to deposit crystals slowly (Stein).

**Tin arsenites.** Scarcely known; both stannous and stannic arsenites seem to exist.

**II. ARSENIC ACID AND ARSENATES.**—(Setterberg, *B. J.* 26, 206; Baumann, *Ar. Ph.* 36, 36; Kodschoenbey, *J. pr.* 49, 182; Field, *C. J.* 11, 6; Uelsmann, *Zeits. f. d. ges. Naturwiss.* 23, 347; Schiff, *A.* 112, 88; Maumené, *C. R.* 58, 250; Debray, *A. Ch.* [3] 61, 419, also *C. R.* 59, 40; Lechartier, *C. R.* 65, 172; Salkowski, *J. pr.* 104, 129). The conditions of formation of the three arsenic acids,  $\text{H}_3\text{AsO}_3$ ,  $\text{HAsO}_3$ , and  $\text{H}_2\text{AsO}_4$ , have been already described (p. 305). The following thermal data are given by Thomsen (*Th.* 2, 236) [ $\text{As}_2\text{O}_3$ ,  $\text{H}^\circ$ ] = 215,630; [ $\text{As}_2\text{O}_3$ ,  $\text{H}^\circ$ ,  $\text{Aq}$ ] = 215,230; [ $\text{As}_2\text{O}_3$ ,  $3\text{H}^\circ\text{O}$ ] = 6,800; [ $\text{As}_2\text{O}_3$ ,  $\text{H}^\circ$ ,  $\text{Aq}$ ] = -400; [ $\text{As}_2\text{O}_3$ ,  $\text{H}^\circ$ ] = 360,830; [ $\text{As}_2\text{O}_3$ ,  $\text{Aq}$ ] = 6,000; [ $\text{As}_2\text{O}_3$ ,  $\text{O}^\circ$ ] = 64,710; [ $\text{As}_2\text{O}_3$ ,  $\text{Aq}$ ,  $\text{O}^\circ$ ] = 78,260. The following heats of neutralisation are also given by Thomsen (*Th.* 1, 196):

$n$ [ $\text{NaOH}$ $\text{Aq}$ , $n\text{H}^\circ\text{AsO}^\circ\text{Aq}$ ];

The acid  $\text{H}_3\text{AsO}_3$  is therefore tribasic; but as the reaction of the third formula-weight of soda is accompanied by the production of not much more than half the quantity of heat which accompanies the reaction of the first or second formula-weight, it is probable that this acid belongs to the same class of tribasic acids as

phosphoric acid, which class is represented by Thomsen by the typical formula  $\text{H}(\text{OH})_2\text{H}$  (*v. ACIDS, BASICITY* or). The relative affinity of arsenic acid (*v. AFFINITY*) is 21 (that of  $\text{HNO}_3$  = 100) which is a little less than the value for phosphoric acid.

The acid  $\text{H}_3\text{AsO}_3$  forms translucent crystals; the acid  $\text{H}_2\text{AsO}_4$  clear lustrous crystals; and the meta-acid  $\text{HAsO}_3$  a white somewhat iridescent solid; the ortho-acid dissolves in water with disappearance of heat (*v. supra*), the other acids dissolve with production of heat and formation of the ortho-acid; [ $\text{HAsO}_3$ ,  $\text{Aq}$ ] = 1,300 (Thomsen, *B.* 7, 1003).

The following facts refer to the ortho-acid  $\text{H}_3\text{AsO}_4$ .

**Formation.**—By action of  $\text{HNO}_3$   $\text{Aq}$  on  $\text{As}$  or  $\text{As}_2\text{O}_3$ .

**Preparation.**—Arsenious oxide is suspended in water and chlorine is passed in; the solution is evaporated to dryness in a platinum dish, the temperature not being allowed to rise much above  $100^\circ$ ; the residue is dissolved in water and evaporated slowly at  $100^\circ$ ; after a time small needle-shaped crystals of  $\text{H}_3\text{AsO}_4$  separate out (E. Kopp, *J. pr.* 69, 270).

**Properties.**—Action of heat already described (*v. p.* 305). Aqueous solution tastes sour and metallic; it burns the skin. The most concentrated solution has S.G. 2.5; the following table gives some data regarding S.G. of aqueous solutions (Schiff, *A.* 113, 183).

S.G. at $15^\circ$	Pctge. of $\text{H}_3\text{AsO}_4$	
1.7346		67.4
1.3973		45.0
1.2350		30.0
1.1606		22.5
1.1052		15.0
1.0495		7.5

**Reactions.**—1. Heated with carbon, many metals, or potassium cyanide, it yields arsenic.—2. Heated with conc. hydrochloric acid  $\text{AsCl}_3$  and  $\text{Cl}$  are produced; if the S.G. of the aqueous  $\text{HCl}$  used is less than 1.04 no  $\text{AsCl}_3$  is produced (Fresenius and Souchay, *Fr.* 1, 448); with acid of S.G. 1.1 traces of  $\text{AsCl}_3$  are formed (Mayrhofer, *A.* 158, 326).—3. Sulphurous acid produces arsenious oxide and sulphuric acid (Wöhler, *A.* 30, 224).—4. Zinc and iron dissolve in aqueous  $\text{H}_3\text{AsO}_4$  with evolution of  $\text{H}$  and  $\text{AsH}_3$  and production of gelatinous solids (? arsenates of  $\text{Zn}$  or  $\text{Fe}$ ); in presence of  $\text{H}_2\text{SO}_4$  these metals precipitate  $\text{As}$ , and evolve  $\text{H}$  and  $\text{AsH}_3$ .—5. Sulphydic acid ( $\text{H}_2\text{S}$ ) reduces  $\text{H}_3\text{AsO}_4$  in solution to  $\text{As}_2\text{S}_3$  with precipitation of  $\text{S}$ , and then throws down  $\text{As}_2\text{S}_3$ ; this reaction takes place slowly at  $10^\circ$ – $15^\circ$ , but more rapidly at  $60^\circ$ – $70^\circ$ .—6. Sodium thiosulphate solution, in presence of  $\text{HCl}$ , produces a pp. of  $\text{As}_2\text{S}_3$  (*q. v.*).—7. Tungstates of potassium, ammonium, and silver when evaporated with  $\text{KH}_2\text{AsO}_4$  solution yield complex compounds, viz.,  $6\text{WO}_3 \cdot \text{As}_2\text{O}_3 \cdot 3\text{K}_2\text{O} \cdot 3\text{H}_2\text{O}$ ;  $6\text{WO}_3 \cdot \text{As}_2\text{O}_3 \cdot 4(\text{NH}_4)_2\text{O} \cdot 5\text{H}_2\text{O}$ ; and  $16\text{WO}_3 \cdot \text{As}_2\text{O}_3 \cdot 6\text{Ag}_2\text{O} \cdot 11\text{H}_2\text{O}$  (Gibbs, *P. Am. A.* 15, 1; 16, 109; *v. also* Debray, *C. R.* 78, 1408; and Seyberth, *B.* 7; also Sonnenschein, *J. pr.* 53, 339, 391). Derivatives of arsenic acid in which  $\text{OH}$  is replaced by  $\text{Cl}$ , or  $\text{Br}$ , or  $\text{I}$ , are not known.

**Arsenates.** Arsenates are isomorphous with corresponding phosphates. The arsenates of the alkali metals, and the acid arsenates of the

alkaline earth metals, are soluble in water; they lose all their arsenic as chloride by strongly heating with sal-ammoniac (Rose, P. 116, 453). The neutral and basic arsenates are easily soluble in mineral acids, including arsenic acid. Debray (*l.c.*) describes a series of amorphous arsenates,  $\text{MH}_2\text{AsO}_4 \cdot \text{H}_2\text{O}$ , obtained by precipitating alkaline arsenates by salts of the metals M; these arsenates become crystalline, according to Debray, by long-continued digestion with the liquids in which they are produced. By fusing chlorides and fluorides with arsenates, Lechartier (*l.c.*) obtained a series of crystalline salts analogous in composition to *Wagnerite* and *Apatite*; thus:

Corresponding to *Wagnerite*  $[(\text{PO}_4)_2\text{F}(\text{Mg}_2)]$ .

Corresponding to *Apatite*  $[(\text{PO}_4)_3\text{Cl}(\text{F})\text{Ca}_3]$ .

Debray also obtained the following crystallised insoluble arsenates by digesting arsenic acid solution with carbonates of the various metals:  $2\text{AsO}_4\text{CaH}_2\text{H}_2\text{O}$ ;  $\text{AsO}_4\text{CuH}$ ;  $2\text{AsO}_4\text{CuH}_2\text{H}_2\text{O}$ ;  $(\text{AsO}_4)_2\text{Cu}_2\text{H}_2\text{O}$ ; and  $\text{AsO}_4\text{Cu}(\text{CuOH})$ . Arsenates are usually prepared by adding  $\text{Na}_2\text{HAsO}_4\text{Aq}$  to solutions of salts of the various metals, using the calculated masses of the reacting bodies.

**Aluminium arsenate.** White pp. by adding a soluble arsenate to a solution of an Al salt.

**Ammonium arsenates.**  $(\text{NH}_4)_2\text{H}_2\text{AsO}_4$ ; by adding  $\text{NH}_3\text{Aq}$  to conc.  $\text{H}_2\text{AsO}_4$  until the pp. which forms is dissolved (Salkowski).  $(\text{NH}_4)_3\text{AsO}_4 \cdot 3\text{H}_2\text{O}$ ; by adding considerable excess of  $\text{NH}_3\text{Aq}$  to  $\text{H}_2\text{AsO}_4\text{Aq}$ .  $\text{NH}_4\text{HAsO}_4$ ; by adding one formula-weight  $\text{H}_2\text{AsO}_4$  to one formula-weight  $(\text{NH}_4)_2\text{HAsO}_4$ .

**Barium arsenates.**  $\text{BaHAsO}_4$ ; crystalline, obtained by adding  $\text{Na}_2\text{HAsO}_4\text{Aq}$  to  $\text{BaCl}_2\text{Aq}$ .  $\text{Ba}_2\text{AsO}_4$ ; crystalline, obtained by adding  $\text{Na}_2\text{AsO}_4\text{Aq}$  to  $\text{BaCl}_2\text{Aq}$ ; acted on by water it forms the salt  $\text{BaHAsO}_4$  (Field). The salt  $\text{BaH}_2(\text{AsO}_4)_2$  is obtained by dissolving  $\text{BaHAsO}_4$  in warm  $\text{H}_2\text{AsO}_4\text{Aq}$  and allowing to crystallise (Setterberg). Two barium-ammonium arsenates  $2\text{Ba} \cdot \text{NH}_4 \cdot \text{AsO}_4 \cdot \text{H}_2\text{O}$ , and  $\text{BaH}_2(\text{NH}_4)_2(\text{AsO}_4)_2$  are described (Baumann, Mitscherlich).

**Bismuth arsenate.**  $2\text{BiAsO}_4 \cdot \text{H}_2\text{O}$ ; yellowish white pp. insoluble in water and  $\text{HNO}_3\text{Aq}$ , soluble in  $\text{HClAq}$ ; insoluble in a conc. solution of  $\text{BiONO}_3$  containing a little free acid (Schneider, J. pr. [2] 20, 418).

**Cadmium arsenates.** White crystalline pps. obtained by precipitating solution of Cd salts by  $\text{Na}_2\text{HAsO}_4\text{Aq}$ ; two are known,  $\text{Cd}_3(\text{AsO}_4)_2 \cdot 3\text{H}_2\text{O}$  and  $\text{Cd}_2\text{H}_2(\text{AsO}_4)_2 \cdot 4\text{H}_2\text{O}$  (Salkowski).

**Calcium arsenates.**  $\text{CaH}_2\text{AsO}_4$ ; prepared like  $\text{BaHAsO}_4$ ; occurs native as *Pharmacolite*. By treatment with  $\text{NH}_3\text{Aq}$  this salt yields  $\text{Ca}_3(\text{AsO}_4)_2$  (Kotschonbey). Two calcium-ammonium arsenates are described,  $\text{CaH}_2(\text{NH}_4)_2(\text{AsO}_4)_2$  and  $\text{CaNH}_4\text{AsO}_4 \cdot 6$  or  $7\text{H}_2\text{O}$  (Baumann, Kotschonbey; also Bloxam, C. N. 54, 163). The salt  $\text{Ca}_3\text{As}_2\text{O}_8$  is obtained by strongly heating  $\text{Ca} \cdot \text{NH}_4 \cdot \text{AsO}_4 \cdot 7\text{H}_2\text{O}$  (Bloxam).

**Cerium arsenate.**  $\text{Ce}_2\text{H}_2\text{AsO}_4$ ; insoluble in water, soluble in excess of  $\text{H}_2\text{AsO}_4\text{Aq}$ .

**Cobalt arsenates.**  $\text{CoHAsO}_4$  is unknown;  $\text{CoH}_2(\text{AsO}_4)_2$  obtained by evaporating *in vacuo* solution of  $\text{CoO} \cdot \text{H}_2\text{O}$  in excess of  $\text{H}_2\text{AsO}_4\text{Aq}$ . Cobaltic arsenate,  $\text{Co}_2\text{AsO}_4 \cdot 8\text{H}_2\text{O}$  (Karsten, P. 60, 266) is a reddish powder obtained by precipitating the solution of a Co salt by  $\text{Na}_2\text{HAsO}_4\text{Aq}$ ; occurs native as *Cobalt-bloom*. An impure basic arsenate of cobalt is known in commerce as *Chaux métallique*.

**Copper arsenates.**  $\text{Cu}_2\text{H}_2(\text{AsO}_4)_2 \cdot 2\text{H}_2\text{O}$ ; obtained as a blue pp. by adding  $(\text{NH}_4)_2\text{HAsO}_4\text{Aq}$  to  $\text{CuSO}_4\text{Aq}$  and drying at  $130^\circ$  (Salkowski).  $\text{Cu}_3(\text{AsO}_4)_2$  is a green powder obtained by precipitating  $\text{CuSO}_4\text{Aq}$  with  $\text{Na}_2\text{HAsO}_4\text{Aq}$ ; this salt dissolves in  $\text{NH}_3\text{Aq}$ , and on long standing, clear blue crystals having the composition  $[(\text{NH}_4)_2\text{Cu}]_3(\text{AsO}_4)_2$  separate out (Damour, B. J. 26, 247; and 27, 181). Various basic arsenates of copper occur native as minerals (v. Coloriano, Bl. [2] 45, 707).

**Chromium arsenates.** Chromic arsenate is a green pp. obtained by mixing solutions of a chromic salt and  $\text{K}_2\text{AsO}_4$ ; composition uncertain. By mixing solutions of  $\text{K}_2\text{CrO}_4$  and  $\text{H}_2\text{AsO}_4$ , Schweizer (J. pr. 39, 267) obtained a gelatinous pp. having the composition (dried at  $100^\circ$ )  $(\text{CrO})_2\text{AsO}_4 \cdot \text{K}_2\text{H}(\text{AsO}_4)_2 \cdot 4\text{H}_2\text{O}$ .

**Didymium arsenate.**  $\text{Di}_2(\text{AsO}_4)_2 \cdot \text{DiH}(\text{AsO}_4)_2 \cdot \text{H}_2\text{O}$ ; by boiling  $\text{H}_2\text{AsO}_4\text{Aq}$  with  $\text{Di}_2\text{O}_3$  (Marignac, A. Ch. 88, 185).

**Iridium arsenate** is a brown pp.

**Iron arsenates.** The ferrous salt is obtained by double decomposition; it oxidises easily; after drying, its composition is  $\text{Fe}_2\text{OAsO}_4 \cdot 5\text{H}_2\text{O}$  (Wittstein, Viertel-jahresschr. pr. Pharm. 15, 185). The ferric salt ( $?\text{FeH}_2(\text{AsO}_4)_2$ ) is obtained by mixing  $\text{FeCl}_3\text{Aq}$  with  $\text{Na}_2\text{HAsO}_4\text{Aq}$ ; it is a white powder which loses water on heating and becomes reddish, soluble in  $\text{H}_2\text{AsO}_4\text{Aq}$ , but this solution soon decomposes, unless very concentrated, depositing  $\text{Fe}_2(\text{OH})_2$  (Lange, Fr. 6, 185). Various other ferric arsenates of uncertain composition have been described by Berzelius (v. also Grimaux, Bl. [2] 42, 211).

**Lead arsenates.** The salt  $\text{PbHAsO}_4$  is obtained by double decomposition (Salkowski); when treated with  $\text{NH}_3\text{Aq}$  it yields  $\text{Pb}_3(\text{AsO}_4)_2$ .

**Lithium arsenates.**  $2\text{Li}_2\text{AsO}_4 \cdot \text{H}_2\text{O}$  is a white powdery pp. obtained by dissolving  $\text{Li}_2\text{CO}_3$  in  $\text{H}_2\text{AsO}_4\text{Aq}$  and adding  $\text{NH}_3\text{Aq}$ ; when this salt is dissolved in  $\text{H}_2\text{AsO}_4\text{Aq}$ , trimetric prisms of  $2\text{LiH}_2\text{AsO}_4 \cdot 3\text{H}_2\text{O}$  crystallise out (Rammelsberg, P. 128, 311).

**Magnesium arsenates.**  $2\text{MgHAsO}_4 \cdot 13\text{H}_2\text{O}$ ; white pp. by mixing 5 parts  $\text{Na}_2\text{HAsO}_4$  in solution with a dilute solution of 3 parts  $\text{MgSO}_4$  (Graham, A. 29, 24).  $\text{Mg}_3(\text{AsO}_4)_2$  is obtained by boiling the preceding salt for some time with conc.  $\text{Na}_2\text{HAsO}_4\text{Aq}$ . A magnesium-ammonium arsenate  $\text{MgNH}_4\text{AsO}_4 \cdot 6\text{H}_2\text{O}$  is obtained by adding  $\text{H}_2\text{AsO}_4\text{Aq}$  with excess of  $\text{NH}_3\text{Aq}$  to  $\text{MgSO}_4\text{Aq}$  containing  $\text{NH}_4\text{Cl}$ ; it is slightly soluble in  $\text{NH}_4\text{ClAq}$ , strongly heated it loses  $\text{NH}_3$  and  $\text{Mg}_2\text{As}_2\text{O}_7$  remains (H. Rose; Field; Wittstein; Puller; Fresenius (Fr. 3, 206); Levol (A. Ch. [3] 17, 50)). A magnesium-potassium arsenate  $\text{MgKAsO}_4$ , and a corresponding sodium salt, are obtained by fusing  $\text{MgHAsO}_4$  with  $\text{K}_2\text{CO}_3$  and  $\text{KOH}$  (or  $\text{Na}_2\text{CO}_3$  and  $\text{NaOH}$ ).

**Manganese arsenates.**  $\text{MnHAsO}_4$  is produced by saturating  $\text{H}_2\text{AsO}_4\text{Aq}$  with  $\text{MnCO}_3$ ; using excess of  $\text{H}_2\text{AsO}_4\text{Aq}$  the salt  $\text{MnH}_2(\text{AsO}_4)_2$  is formed (Schiefer). The manganese-ammonium salt  $\text{MnNH}_4\text{AsO}_4 \cdot 6\text{H}_2\text{O}$  is obtained like the corresponding Mg salt as a gummy pp. which becomes crystalline. Some basic Mn arsenates are described by Coloriano (*Bl.* [2] 45, 709).

**Mercury arsenates.** The mercurous salt  $\text{Hg}_2\text{HAsO}_4$  is a yellowish white pp., which becomes orange red, produced by adding  $\text{H}_2\text{AsO}_4\text{Aq}$  to  $\text{HgNO}_3\text{Aq}$ ; it is insoluble in water and  $\text{H}_2\text{C}_2\text{H}_3\text{O}_2\text{Aq}$ , soluble in  $\text{HNO}_3\text{Aq}$ . When heated, this salt loses  $\text{H}_2\text{O}$  and Hg, and a mercuric salt (probably  $\text{Hg}_2\text{As}_2\text{O}_7$ ) remains. By adding an excess of  $\text{H}_2\text{AsO}_4\text{Aq}$  to the mercurous salt, and evaporating, the meta-salt  $\text{Hg}_2(\text{AsO}_4)_2$  is obtained as a white powder, somewhat soluble in  $\text{HNO}_3\text{Aq}$ , decomposed by  $\text{HClAq}$  with formation of  $\text{HgCl}_2$ , decomposed by  $\text{KOH Aq}$  with withdrawal of half its arsenic as  $\text{H}_2\text{AsO}_4$  (Simon, *P.* 41, 421).

**Molybdenum arsenate** is a grey pp. (for combinations of  $\text{As}_2\text{O}_5$  with  $\text{MoO}_3$  and  $\text{K}_2\text{O}$  v. ARSENIC ACID, Reactions, No. 7).

**Nickel arsenates.** Analogous to cobalt arsenates (*q. v.*). The salt  $\text{Ni}_3(\text{AsO}_4)_2 \cdot 8\text{H}_2\text{O}$  occurs native as *Nickel-bloom*.

**Palladium arsenate** is a clear yellow pp. obtained by heating  $\text{Na}_2\text{HAsO}_4\text{Aq}$  with  $\text{Pd}_2\text{NO}_3\text{Aq}$ .

**Platinum arsenate** is a light-brown pp. obtained like the Pd salt.

**Potassium arsenates.** The salts  $\text{K}_2\text{AsO}_4$  and  $\text{K}_3\text{HAsO}_4$  are obtained by adding  $\text{K}_2\text{CO}_3$  or  $\text{KOH}$  to  $\text{H}_2\text{AsO}_4\text{Aq}$ ; the former crystallises from very conc. solutions (Graham, *P.* 32, 47). By heating together equal parts of  $\text{KNO}_3$  and  $\text{As}_2\text{O}_5$ , dissolving in water and evaporating, or by adding  $\text{KOH Aq}$  to  $\text{H}_2\text{AsO}_4\text{Aq}$  until neutral to litmus and crystallising, the salt  $\text{KH}_2\text{AsO}_4$  is obtained. The crystals of this salt are fairly soluble in water ( $S. 6^\circ = 19$ ), insoluble in alcohol. Heated above  $288^\circ$  the salt melts to a glassy mass.

**Silver arsenates.**  $\text{Ag}_3\text{AsO}_4$  is a dark red-brown pp. produced by mixing  $\text{H}_2\text{AsO}_4\text{Aq}$ , or solution of an alkaline arsenate, with  $\text{AgNO}_3\text{Aq}$ ; it melts to a brownish-red glass, it is decomposed by  $\text{HClAq}$  to  $\text{AgCl}$  and  $\text{H}_2\text{AsO}_4\text{Aq}$ , it is soluble in  $\text{HClO}_4\text{Aq}$ ,  $\text{NH}_3\text{Aq}$ , and solutions of many  $\text{NH}_4$  salts. By digesting this salt for some time at a gentle heat with  $\text{H}_2\text{AsO}_4\text{Aq}$  a white salt,  $2\text{AgAsO}_3 \cdot \text{As}_2\text{O}_5$ , is obtained.

**Sodium arsenates.**  $\text{Na}_2\text{HAsO}_4 \cdot 12\text{H}_2\text{O}$ , S.G. 1.67 (Schiff), is obtained in large crystals, isomorphous with common sodium phosphate, by adding a slight excess of  $\text{Na}_2\text{CO}_3\text{Aq}$  to  $\text{H}_2\text{AsO}_4\text{Aq}$ , and evaporating at a temperature not higher than  $18^\circ$  (Fresenius, *J. pr.* 56, 30). The crystals which form at  $20^\circ$  and upwards contain  $7\text{H}_2\text{O}$ , S.G. 1.87 (Schiff); the crystals with  $12\text{H}_2\text{O}$  effloresce quickly, those with  $7\text{H}_2\text{O}$  do not. The salt melts when heated forming a clear transparent liquid. At  $0^\circ$  a salt crystallises with  $13\frac{1}{2}\text{H}_2\text{O}$  (Setterberg). The salt  $\text{NaH}_2\text{AsO}_4 \cdot \text{H}_2\text{O}$  is formed in large crystals by adding  $\text{Na}_2\text{CO}_3\text{Aq}$  to  $\text{H}_2\text{AsO}_4\text{Aq}$  until the solution is no longer ppd. by  $\text{BaCl}_2\text{Aq}$ ; isomorphous with the corresponding phosphate; S.G. 2.635 (Schiff). A solution of S.G. about 1.7 gives crystals of  $\text{NaH}_2\text{AsO}_4 \cdot 2\text{H}_2\text{O}$  (Joly a.

Dufet, *C. R.* 102, 1391). A conc. solution of  $\text{H}_2\text{AsO}_4$  decomposes  $\text{NaClAq}$  and  $\text{NaNO}_3$  on heating. Two double salts, viz.  $\text{NaKHAsO}_4 \cdot 7\text{H}_2\text{O}$  (Schiff), or  $9\text{H}_2\text{O}$  (Kotschobey), and  $\text{NaNH}_4\text{HAsO}_4 \cdot 4\text{H}_2\text{O}$ , are described (Uelsmann). The former is obtained by neutralising  $\text{NaH}_2\text{AsO}_4\text{Aq}$  by  $\text{K}_2\text{CO}_3\text{Aq}$ , the latter by mixing solutions of  $\text{Na}_2\text{HAsO}_4$  and  $(\text{NH}_4)_2\text{HAsO}_4$ . The compound  $\text{Na}_2\text{AsO}_4 \cdot \text{NaF} \cdot 12\text{H}_2\text{O}$  crystallises in monometric octahedra; it resembles common alum in appearance; S.G. 2.849;  $S. (25^\circ) = 10.5$ ;  $S. (75^\circ) = 50$ . This salt is obtained by fusing together, with special precautions, 1 part  $\text{As}_2\text{O}_5$ , 4 parts  $\text{Na}_2\text{CO}_3$ , 3 parts  $\text{NaNO}_3$ , and 1 part  $\text{CaF}_2$  (Briegleb, *A.* 97, 95). Two compounds of sodium arsenates with sulphates seem to exist  $\text{Na}_2\text{As}_2\text{O}_7 \cdot 2\text{Na}_2\text{SO}_4$  (Mitscherlich), and  $\text{Na}_2\text{As}_2\text{O}_7 \cdot \text{Na}_2\text{SO}_4$  (Setterberg).

**Strontium arsenates.** By adding  $\text{Na}_2\text{HAsO}_4\text{Aq}$  to  $\text{SrCl}_2\text{Aq}$  a pp. of  $\text{SrNaAsO}_4 \cdot \text{H}_2\text{O}$  is obtained; the filtrate from this when evaporated gives a white pp. of  $\text{SrHAsO}_4$  (Salkowski).

**Tin arsenates.**  $2\text{SnHAsO}_4 \cdot \text{H}_2\text{O}$ ; a white pp. produced by adding excess of  $\text{K}_2\text{HAsO}_4\text{Aq}$  to  $\text{SnCl}_2\text{Aq}$ ; by the reverse process the salt  $\text{Sn}(\text{SnCl})\text{AsO}_4 \cdot \text{H}_2\text{O}$  is said to be formed (Lennsen, *A.* 114, 113).

**Zinc arsenate**  $\text{Zn}_3(\text{AsO}_4)_2 \cdot 3\text{H}_2\text{O}$  is a gelatinous substance (Köttig, *J. pr.* 48, 182 and 256); the salts  $\text{ZnHAsO}_4$ ,  $\text{ZnH}_2(\text{AsO}_4)_2$ , and  $\text{Zn}_3(\text{AsO}_4)_2 \cdot \text{NH}_3$ , are also known (*v. also* Friedel, *Bl.* [2] 5, 433).

The compositions of the remaining arsenates, which have been very slightly investigated, are expressed by the following formulæ:—

**Thallium**,  $\text{TlAsO}_4 \cdot 2\text{H}_2\text{O}$ . **Thorium**,  $\text{Th}_2\text{HAsO}_4$ . **Uranium**,  $(\text{UO}_2)_2\text{HAsO}_4 \cdot 4\text{H}_2\text{O}$ ; the salts  $(\text{UO}_2)_2\text{NaAsO}_4$  and  $(\text{UO}_2)_2\text{Cu}(\text{AsO}_4)_2 \cdot 8\text{H}_2\text{O}$  are also known (Werther, *A.* 68, 312). **Vanadium**,  $\text{VH}_2(\text{AsO}_4)_2$ . **Yttrium**,  $\text{YHAsO}_4$ . Arsenates of titanium and zirconium are said to have been obtained.

**Arsenic, alloys of, v. ARSENIC, Combinations of, No. 9.**

**Arsenic, ammonio-chloride of, v. ARSENIO CHLORIDE, Combinations of, No. 2.**

**Arsenic, bromide of.**  $\text{AsBr}_3$  (*Arsenious bromide, Tribromide of arsenic*). Mol. w. 314.25.  $[20^\circ - 25^\circ]$ . S.G. 3.66 (Boedeker, *J.* 1860, 17). V.D. 157.5. H.F. 59, 100 solid As, gaseous Br (Guntz, *C. R.* 101, 161). S.V.S. 85.8.

**Preparation.**—1. Powdered arsenic is shaken into a retort filled with Br vapour, and the bromide is distilled from the excess of As.—2. Powdered arsenic is added to a mixture of 1 part Br with 2 parts  $\text{CS}_2$  until the liquid is colourless; more Br is then added, followed by more As, until the colour is no longer removed on the addition of As; the liquid is then filtered and evaporated; on standing, the bromide is deposited in crystals (Nicklès, *C. R.* 69, 837; *J. Ph.* [3] 41, 142).

**Properties.**—Colourless deliquescent prisms with strong arsenical odour, melting to a pale yellow liquid which fumes but slightly in the air. Volatilises unchanged and yields a crystalline sublimate.

**Reactions.**—1. Water, added in small quantity, produces  $\text{AsOBr}$  and  $\text{HBr}$  (? with a little arsenious oxide) (Serullas, *S.* 55, 345); added in large quantity, decomposes it into  $\text{HBr}$  and

$\text{As}_2\text{O}_3$  (Serrillas, l.c.). An aqueous solution containing  $\text{HBr}$  deposits the oxy-salts  $2\text{AsOBr} \cdot 8\text{As}_2\text{O}_3 \cdot 12\text{H}_2\text{O}$  and  $2\text{AsOBr} \cdot 3\text{H}_2\text{O}$  (Wallace, *P. M.* [4] 17, 261).—2. *Ammonium bromide* added to a cold concentrated aqueous solution pps. six-sided tables consisting chiefly of  $\text{AsBr}_3$  (Wallace, *P. M.* [4] 17, 261).—3. *Sodium thiosulphate* at first produces  $\text{AsOBr}$ , and then  $\text{As}_2\text{S}_3$  (Nicklès, *J. Ph.* [3] 41, 142).—4. *Arsenious oxide* dissolves in molten  $\text{AsBr}_3$ ; on cooling to  $150^\circ$  the liquid separates into two layers, the upper of which is  $\text{AsOBr}$ , and the lower probably  $3\text{AsOBr} \cdot \text{As}_2\text{O}_3$  (Wallace, *P. M.* [4] 17, 261).

**Combinations.**—With the *alkaline bromides* to form rather unstable crystallisable compounds (Nicklès, l.c.).

**Arsenic, chloride of.**  $\text{AsCl}_3$  (*Arsenious chloride*, *Trichloride of arsenic*, *Butler of arsenic*, *Caustic oil of arsenic*). Mol. w. 181.11. [below  $29^\circ$ ]. ( $130^\circ \cdot 2$ ) (Thorpe, *C. J.* 37, 352). S.G.  $\frac{4}{5}$  2.205 (Thorpe, l.c.). V.D. 90.75. Volume at  $t^\circ = \text{vol. at } 0^\circ + 0.000991338t + 0.00000849t^2 + 0.000000027551t^3$  (Thorpe, l.c.). S.H.p. 1122; S.H.v. 7034; H.V. 69.74 (Regnault, *J.* 1863, 77). H.F. 71.460 (solid  $\text{As}$  and gaseous  $\text{Cl}$ ) (*Th.* 2, 326). R<sub>4</sub> 49.59 (Haagen, *P.* 131, 122). S.V. 94.37 (Thorpe, l.c.).

**Formation.**—1. By distilling  $\text{As}_2\text{O}_3$  with conc.  $\text{H}_2\text{SO}_4$  and  $\text{NaCl}$  (Glauber in 1618; Dumas, *P.* 9, 308).—2. By distilling  $\text{As}_2\text{O}_3$  with conc.  $\text{HCl}$ .—3. By leading dry  $\text{HCl}$  gas over powdered  $\text{As}_2\text{O}_3$ .—4. By passing dry  $\text{HCl}$  gas over gently heated powdered  $\text{As}_2\text{O}_3$ ;  $\text{As}_2\text{O}_3 + 10\text{HCl} = 2\text{AsCl}_3 + 2\text{Cl}_2 + 5\text{H}_2\text{O}$  (Mayrhofer, *A.* 158, 326).—5. By adding  $\text{H}_2\text{SO}_4$  to a solution of  $\text{As}_2\text{O}_3$  in conc.  $\text{HCl}$ .—6. By heating  $\text{As}_2\text{S}_3$  with  $3\text{HgCl}_2$  in a retort (Ludwig, *Ar. Ph.* 97, 23).—7. By the action of  $\text{S}_2\text{Cl}_2$  on  $\text{As}$  (Wöhler, *A.* 73, 374).—8. By the action of  $\text{PCl}_5$  on  $\text{As}_2\text{O}_3$  or on  $\text{As}_2\text{O}_5$  ( $\text{POCl}_3$ ), and in the case of  $\text{As}_2\text{O}_3$  free  $\text{Cl}$  is also formed (Hintzig and Geuther, *A.* 111, 171).

**Preparation.**—Coarsely powdered arsenic is heated in a retort, dry chlorine is then led in, and the contents of the retort are heated; the distillate is collected in a dry receiver, and freed from excess of chlorine by redistillation from arsenic, or by shaking with mercury, pouring off from the black solid which is formed, and redistilling. Or the product may be distilled upwards for some time in a current of dry  $\text{CO}_2$  (Thorpe, l.c.).

**Properties.**—A colourless, oily, fuming, very poisonous, liquid; mixes with alcohol, ether, and liquid oils; it is decomposed by water (*v. infra*). Distilled with aqueous  $\text{HCl}$ ,  $\text{AsCl}_3$  is partly volatilised;  $\text{HCl}$  prepared from arsenic containing  $\text{H}_2\text{SO}_4$  always therefore contains  $\text{AsCl}_3$ ; arsenious chloride when hot dissolves phosphorus and sulphur, but they crystallise out again on cooling.

**Reactions.**—1. With a little water the solid oxychloride  $\text{AsOCl} \cdot \text{H}_2\text{O}$  ( $= \text{As}(\text{OH})_2\text{Cl}$ ) is produced (Wallace, *P. M.* [4] 16, 358). With more water, especially if hot,  $\text{AsCl}_3$  is decomposed into  $\text{HCl}$  and  $\text{As}_2\text{O}_3$ , a great portion of the latter separating in the solid form.—2. With *arsenic hydride* it reacts to form  $\text{HCl}$  and  $\text{As}$ .—3. By the action of  $\text{NO}_2$  it is converted into  $\text{As}_2\text{O}_5$ ,  $\text{NOCl}$  being

simultaneously produced (Geuther, *J. pr.* [3] 6, 854).

**Combinations.**—1. *Arsenious oxide* dissolves in boiling  $\text{AsCl}_3$ , and on distillation the oxychloride  $\text{AsOCl}$  (*q. v.*) is obtained (Wallace, *P. M.* [4] 16, 358).—2. *Ammonia gas* is absorbed by  $\text{AsCl}_3$  with production of a white solid,  $2\text{AsCl}_3 \cdot 7\text{NH}_3$ , according to H. Rose (*P.* 52, 62),  $2\text{AsCl}_3 \cdot 4\text{NH}_3 \cdot \text{Cl} \cdot \text{NH}_3$ , according to Pasteur (*A. Ch.* 68, 307), Michaelis suggests the formula  $2\text{As}(\text{NH}_4\text{Cl})_3 \cdot \text{NH}_3$  (*Lehrbuch der anorg. Chem.* ii. 459, [1881]); this compound is decomposed by heat, giving off  $\text{NH}_3$ , and then a white sublimate containing  $\text{NH}_4\text{Cl}$ ; it is soluble in alcohol, but is decomposed by cold water with production of heat and ammonia, from the solution six-sided plates crystallise out, having the composition  $\text{AsCl}_3 \cdot \text{NH}_3 \cdot \text{H}_2\text{O}$ , these are decomposed by conc. ammonia with production of  $(\text{NH}_4)_2\text{AsO}_4$ , which soon decomposes (Pasteur, l.c.).—3. *Sulphur dichloride*,  $\text{SCl}_2$ , is said to form a compound  $2\text{AsCl}_3 \cdot 3\text{SCl}_2$ , but according to Nilson, the product of the action is merely a mixture (*J. pr.* [2] 12, 295).—4. With *alcohol* forms easily decomposed crystals of  $\text{AsCl}_3 \cdot \text{C}_2\text{H}_5\text{O}$  (De Luynes, *C. R.* 50, 831).

**Arsenic, fluoride of.**  $\text{AsF}_3$  (*Arsenious fluoride*). Mol. w. 131.9. ( $60^\circ \cdot 4$ ) (Thorpe, *C. J.* 37, 352). S.G.  $\frac{4}{5}$  2.666 (Thorpe, l.c.). V.D. 66.1. S.V.S. 49.5.

**Formation.**—By heating sodium or ammonium fluoride with arsenious bromide or chloride (Macivor, *C. N.* 30, 169).

**Preparation.**—Equal parts of dry powdered fluorspar and arsenious oxide are heated in a leaden vessel with 5 parts conc.  $\text{H}_2\text{SO}_4$ ; the distillate is collected in a dry glass receiver.

**Properties.**—A transparent, very volatile, fuming, liquid; it acts slowly on glass in a closed vessel, but exposed to the air it absorbs moisture with production of  $\text{As}_2\text{O}_3$  and  $\text{HF}$  which acts on the glass. Dropped on the skin it evaporates at once but leaves a painful wound (Dumas, *A. Ch.* [2] 31, 434). It absorbs dry  $\text{NH}_3$  in large quantities; miscible with alcohol and ether (Macivor, l.c.).

**Reaction.**—With water it forms a clear liquid (heat is produced) which soon decomposes to  $\text{As}_2\text{O}_3$  and  $\text{HF}$ .

**Arsenic, haloid compounds of.**  $\text{AsF}_3$ ,  $\text{AsCl}_3$ ;  $\text{AsBr}_3$ ;  $\text{AsI}_3$  and  $\text{AsL}_3$  (?  $\text{AsI}_3$ ). All gasified, except the di- and pent-iodide, and molecular weights known; *v. the arts.* ARSENIC, FLUORIDE OF, CHLORIDE OF, BROMIDE OF, IODIDES OF, *v. also art.* HALOID COMPOUNDS.

**Arsenic, hydrides of.** (In connection with these compounds *v. art.* HYDRIDES.) Two hydrides are known; gaseous  $\text{AsH}_3$ , and solid  $\text{nAsH}$ .

1. ARSENIC TRIHYDRIDE.  $\text{AsH}_3$  (*Arsenuretted hydrogen*; *Arsine*). Mol. w. 77.9. ( $-113^\circ \cdot 5$ ). ( $-54^\circ \cdot 8$ ) (Olszewski, *Sitz. W.* 5, 127) (about  $-40^\circ$ ). V.D. 39.1 (Dumas, *A. Ch.* 33, 355). H.F. = 861,700 (solid  $\text{As}$ ) (Ogier, *A. Ch.* [5] 20, 5). Discovered by Scheele in 1775.

**Formation.**—1. By dissolving zinc or iron in dilute  $\text{HClAq}$  or  $\text{H}_2\text{SO}_4\text{Aq}$  containing  $\text{As}_2\text{O}_3$  or  $\text{As}_2\text{O}_5$ .—2. By electrolysis of solution of  $\text{As}_2\text{O}_3\text{Aq}$  or  $\text{As}_2\text{O}_5\text{Aq}$ .—3. By the action of organic matter on many arsenic compounds; *e.g.* the action of paper on Scheele's green (the air of

rooms the paper on the walls of which is coloured with Scheele's green usually contains a little  $\text{AsH}_3$ .

**Preparation.**—1. By the action of water, or better very dilute  $\text{HCl}$  or  $\text{H}_2\text{SO}_4$ , on the solid alloy of As and Na which is obtained by heating Na in  $\text{AsH}_3$  obtained by the action of acids on Zn containing As (Janowsky, *B. 6*, 216).—2. By the action of  $\text{H}_2\text{SO}_4$  diluted with 8 times its weight of water on the alloy of As and Zn obtained by heating equal parts of finely granulated Zn and powdered As in a covered crucible (Soubeiran, *A. Ch.* [2] 23, 307; 43, 207). The gas is collected over boiled water.

**Properties.**—A colourless gas with repulsive odour; excessively poisonous (in working with this gas it is impossible to be too careful; more than one chemist has been killed by it, e.g. Gehlen in 1815). Easily decomposed by heat into its elements even when mixed with much hydrogen. By the action of the silent electric discharge it yields solid As hydride (Ogier, *A. Ch.* [5] 20, 5). Slightly soluble in water. Dry oxygen has no action at ordinary temperatures.

**Reactions.**—1. Heated in air it burns to  $\text{As}_2\text{O}_3$  and  $\text{H}_2\text{O}$ ; in a limited supply of air, to As and  $\text{H}_2\text{O}$ .—2. Mixed with oxygen and subjected to electric discharge, complete decomposition to  $\text{As}_2\text{O}_3$  and  $\text{H}_2\text{O}$  occurs explosively.—3. Concentrated acids decompose it into its elements; conc.  $\text{H}_2\text{SO}_4$  forms also  $\text{As}_2\text{S}_3$  (Humpert, *J. pr.* 94, 392); conc.  $\text{HClAq}$  acting for some time forms also  $\text{AsCl}_3$  (Napoli, *J. pr.* 64, 93).—4. Decomposed by chlorine, bromine, or iodine, with production of much heat and formation of haloid compounds of As.—5. *Sulphuretted hydrogen* at about  $300^\circ$  forms  $\text{As}_2\text{S}_3$  and H.—6. The haloid acids  $\text{HCl}$ ,  $\text{HBr}$ ,  $\text{HI}$ , are without action on  $\text{AsH}_3$  at ordinary temperatures.—7. Heated with sulphur,  $\text{As}_2\text{S}_3$  and  $\text{H}_2\text{S}$  are produced (Jones, *C. J.* [2] 14, 618).—8. Reacts with  $\text{PCl}_3$  to produce  $\text{AsP}$  and  $\text{HCl}$  (v. **ARSENIC COMBINATIONS**, of No. 8).—9. Many metals, e.g. K, Na, Sn, heated in  $\text{AsH}_3$  form alloys with As and set free  $\text{H}_2$ .—10. Many metallic oxides, e.g.  $\text{CuO}$ , decompose  $\text{AsH}_3$  when heated with it, forming arsenides and water (the quantity of  $\text{AsH}_3$  in a gaseous mixture may be thus determined).—11. Absorbed and slowly decomposed by alkalis, and by water containing oxygen or air.—12. Many metallic salts in aqueous solutions absorb and decompose  $\text{AsH}_3$ ; salts of metals whose oxides are easily deoxidised produce water and arsenious oxide; salts of metals whose oxides are not so easily deoxidised produce water and arsenic which is precipitated with the metal. Thus with (1)  $\text{AgNO}_3$ , and (2)  $\text{CuSO}_4$ , solution, the reactions are

**References.**—(Besides those in the text) Marsh, *B. J.* 17, 191; 20, 190; 22, 175; Stromeyer, *Comment. Soc. Götting.* 16, 141; Proust, *Scher. J.* 8, 285; Fischer, *P. 9*, 261; Myers, *A.* 159, 127; Parsons, *C. N.* 35, 235.

II. SOLID ARSENIC HYDRIDE,  $n\text{AsH}$ . Mol. w. unknown. Janowsky (*B. 6*, 220) states that when potassium or sodium arsenide is decom-

posed by water, a solid, brown, velvet-like, compound of As and H, in the ratio  $\text{As:H}$ , separates out. When dilute acids are used in place of water,  $\text{AsH}_3$  is evolved and As deposited. According to Ogier (*A. Ch.* [5] 20, 5), solid  $n\text{AsH}$  is produced by the action of the silent discharge on  $\text{AsH}_3$ . Older observations recorded the production of a solid compound of As and H by the action of dilute acids on arsenide of zinc (v. especially Wiederhold, *P.* 118, 615), but these are contradicted by Janowsky (*loc.*). According to Blondlot (*A. Ch.* [3] 68, 186), a solid hydride of arsenic is produced (1) in a Marsh's apparatus when a little  $\text{HNO}_3$  is present, and (2) when  $\text{AsH}_3$  is passed into aqueous  $\text{AgNO}_3$ , excess of Ag is removed by adding  $\text{NaCl}$ , a drop of  $\text{HNO}_3$  is added, and a piece of Zn is placed in the liquid.

**Arsenic, hydroxides of.** The compounds of As, O, and H, are acids; v. **ARSENIC ACIDS** or (v. also arts. **ACIDS**, and **HYDROXIDES**).

**Arsenic, iodides of.**

I. ARSENIOUS IODIDE,  $\text{AsI}_3$  (*Triiodide of arsenic*). Mol. w. 454.59, ( $394^\circ$  to  $414^\circ$ ) (Carnelley a. Williams, *C. J.* 33, 283). S.G. 4.39. V.D. 227.3. S.  $30-12$  at  $100^\circ$ . H.F. solid As, gaseous I [ $\text{As, I}$ ] = 28,800 (Guntz, *C. R.* 101, 161). S.V.S. 103.6.

**Formation.**—1. By subliming together 1 part As and 3 parts I in a retort arranged so that the sublimate condenses in the neck; the sublimate is treated with hot alcohol from which the  $\text{AsI}_3$  crystallises on cooling (Bette, *A.* 33, 349).—2. By boiling 3 parts powdered As and 10 parts I with water, filtering, and evaporating (Pliesson, *S.* 55, 335).—3. By acting on  $\text{AsCl}_3$  with conc.  $\text{HI}$  solution ( $\text{HI}$  is evolved) (Hautefeuille, *Bl.* [2] 7, 198).—4. By adding a concentrated solution of KI to a hot solution of  $\text{As}_2\text{O}_3$  in  $\text{HClAq}$  (Bamberger a. Philipp, *B.* 14, 2643).

**Preparation.**—A saturated solution of iodine in ether is heated to boiling with excess of powdered As in a flask with an upright condenser; the liquid is filtered while hot; on cooling, well-formed crystals of  $\text{AsI}_3$  are obtained (Wiggers, Michaelis's *Lehrbuch der anorgan. Chem.* [1881] 2, 462).

**Properties and Reactions.**—Lustrous, red, hexagonal, tables,  $a:c = 1:2.998$  (details of crystal form, v. Friedländer, *Z. K.* 3, 214). Soluble in alcohol, ether, benzene, &c.; soluble in much water; soluble without change in alcohol; decomposed by a little water with formation of  $4\text{AsOI} \cdot 3\text{As}_2\text{O}_3 \cdot 24\text{H}_2\text{O}$ ; action of boiling  $\text{H}_2\text{O}$  produces  $\text{AsOI} \cdot \text{As}_2\text{O}_3$  which deposits on cooling (Wallace, *P. M.* [4] 17, 122).

**Combinations.**—1. With iodides of the alkali metals to form very unstable compounds (Nicklès, *C. R.* 48, 237).—2. When ammonia is passed into a solution of  $\text{AsI}_3$  in benzene, a bulky white pp. of  $2\text{AsI}_3 \cdot 9\text{NH}_3$  is produced (Bamberger a. Philipp, *B.* 14, 2613).

**Reactions.**—1. Heated with oxygen, iodine is evolved and  $\text{As}_2\text{O}_3$  is produced.—2. Heated with alcohol, ethylic iodide is formed (Bamberger a. Philipp, *B.* 14, 2643).

II. ARSENIC DIODIDE.  $\text{AsI}_2$  (Bamberger a. Philipp, *B.* 14, 2643). Mol. w. unknown.

**Preparation.**—One part As is heated with 2 parts I to  $230^\circ$  in a sealed tube, the product is

dissolved in  $\text{CS}_2$  in an atmosphere of  $\text{CO}_2$ , and the liquid is allowed to deposit crystals.

**Properties.**—Thin prisms of a dark cherry-red colour.

**Reactions.**—Very easily oxidised. Decomposed by water to  $\text{AsI}_3$  and  $\text{As}$ ; ( $3\text{AsI}_3 = 2\text{AsI}_2 + \text{As}$ ).

III. ARSENIC PENTIOXIDE. According to Sloan (*C. N.* 46, 194) a brown crystalline solid, containing  $\text{As}$  and  $\text{I}$  in the ratio  $\text{As}:\text{I} = 5:1$ , is obtained by heating  $\text{As}$  with a slight excess of  $\text{I}$  to  $100^\circ$  for some time in an atmosphere of  $\text{CO}_2$ . The body is easily decomposed to  $\text{AsI}_3$  and  $\text{I}$ , by heat or by solution in ether or  $\text{CS}_2$ .

**Arsenic oxides of.** (In connection with these compounds, *v. art. Oxides.*) Arsenic forms two well-defined oxides, arsenious oxide  $\text{As}_2\text{O}_3$ , which has been gasified; and arsenic oxide,  $\text{As}_2\text{O}_5$ , which has not been gasified: both act as anhydrides; the acid corresponding to the former is not known, but many arsenites,  $\text{M}_2\text{AsO}_3$ , have been prepared. Three arsenic acids are known corresponding in composition to the three phosphoric acids, two of these exist only as solids, they all readily lose water yielding the anhydride  $\text{As}_2\text{O}_5$ . The greyish film which forms on the surface of arsenic exposed to the air has been regarded as a suboxide, but no definite proof of the existence of an oxide with less  $\text{O}$  than  $\text{As}_2\text{O}_5$  has been given.

I. ARSENIOUS OXIDE.  $\text{As}_2\text{O}_3$ . Mol. w. 395.36. (*Arsenic trioxide, White arsenic, Arsenious anhydride, Arsenious acid.*) Vitreous  $\text{As}_2\text{O}_3$  melts under pressure, crystalline vaporises without melting (Wöhler, *Gm.* 4, 255). S.G. vitreous 3.698 to 3.738; cryst. 3.85 to 4.15 (*v. Claudet, C. J.* [2] 6, 179, and Groth, *P.* 137, 426). V.D. 198 (at white heat, *V. Meyer, B.* 12, 1117). C.E. (cubic at  $40^\circ$ ) .00012378 (Fizeau, *C. R.* 63, 1133). S. ( $13^\circ$ ) vitreous, 4; cryst. 1.2 to 1.3. S. ( $100^\circ$ ) 11 (Bussy, *A.* 64, 286). S. ( $15^\circ$  standing for some days) cryst. .28; vitreous .92, S. (saturated at  $100^\circ$  and then cooled to  $15^\circ$ ) cryst. 2.18; vitreous, 3.33 (Buchner, *J. Ph.* [3] 1, 421). S. (alcohol,  $15^\circ$ ) cryst. .25; vitreous, 1.06 (Girardin, *J. Ph.* [3] 46, 269). S. (ether) 0. H.F. 309,310; H.F. in aqueous solution, 294,240; [ $\text{As}^\circ\text{O}^\circ\text{Aq}$ ] = -15,100 (*Tk.* 2, 236). S.H. cryst. .1279. S.V.S. vitreous, 106.3; cryst. 98.9.

**Occurrence.**—Native, as the mineral *Arsenite* (or *Arsenolite*); whenever arsenic volatilises in contact with air, or arsenic-containing minerals are heated in air.

**Preparation.**—Obtained as a principal product in the roasting of arsenical pyrites, and as a secondary product in the roasting of arsenical ores of  $\text{Sn}$ ,  $\text{Co}$ ,  $\text{Ni}$ , or  $\text{Ag}$ . The oxide is condensed in chambers, and purified by resublimation. Extremely poisonous; doses of 0.6 gram are usually fatal (but *v. Roscoe* 'On the alleged Practice of Arsenic-eating in Styria,' *Mem. of Lit. and Phil. Soc. of Manchester*, 1860).

**Properties.**—Exists in three forms, amorphous, regular octahedra, and trimetric prisms ( $a:b:c = 3758:1:35$ ); the first passes slowly into the second form on keeping; the third is obtained under special conditions (*v. infra*). The change from amorphous to octahedral arsenious oxide is attended with production of 5,300 gram-units of heat, and that from amorphous to prismatic with 24,950 units per  $\text{As}_2\text{O}_3$  grams (Favre;

Troost and Hautefeuille, *C. R.* 69, 49). Amorphous arsenious oxide is produced by condensing the vapour on a surface slightly cooler than the temperature of volatilisation of the oxide; it is a transparent glass-like solid which gradually becomes opaque because of formation of octahedral crystals. The octahedral oxide is produced by cooling the vapour quickly; by crystallising either of the other forms from water; by treating the amorphous form with ammonia solution and washing with water. This form is obtained pure by fusing commercial arsenious oxide with carbonate of sodium and nitre, dissolving the arsenate of sodium so formed in water, filtering from sodium antimonate which remains, and reducing with  $\text{SO}_2$  solution. According to H. Rose (*P.* 35, 481) a solution of 2-3 parts amorphous  $\text{As}_2\text{O}_3$  in 12 parts boiling conc.  $\text{HClAq}$  deposits crystals of the octahedral oxide when very slowly cooled, the formation of each crystal being accompanied by a flash of light; a similar solution of the crystalline oxide does not behave in this way. The trimetric prismatic variety of  $\text{As}_2\text{O}_3$  is obtained by saturating with  $\text{As}_2\text{O}_3$ , and then allowing to cool, a boiling solution of potash (Pasteur, *C. R.* 21, 474); Wöhler found this oxide in an oven in which arsenical ores had been roasted (*P.* 26, 177); Claudet found it native at San Domingos, in Portugal (*C. J.* [2] 6, 179); Kühn obtained it from a solution of  $\text{Ag}_3\text{AsO}_3$  in  $\text{HNO}_3$  (*J.* 1852, 378; *v. also* Uhricht, *J.* 1858, 173); Scheurer-Kestner found it in pipes leading from the pyrites burners to the chambers of a sulphuric acid works (*Bl.* [2] 10, 444). The three forms of  $\text{As}_2\text{O}_3$  may be obtained, according to Debray (*C. R.* 58, 1209), by heating the oxide in a closed glass tube half immersed in sand, in an upright position, the lower part being at about  $400^\circ$ ; on cooling, the lowest part of the tube contains amorphous, the middle part trimetric crystals, and the uppermost part octahedral crystals, of  $\text{As}_2\text{O}_3$ . Arsenious oxide is iso-dimorphous with antimonious oxide. The vitreous (amorphous) variety may be fused before volatilising; the crystalline sublimes without melting, even under pressure (Wöhler, *Gm.* 4, 255). The vapour is colourless and inodorous. The solubilities in water of the three forms are different (*v. supra*); long-continued contact with hot water decreases the solubility of the vitreous form inasmuch as it is thus changed to the octahedral form. Many acids dissolve  $\text{As}_2\text{O}_3$ , the vitreous more rapidly than the crystalline varieties (Bacaloglo, *J. pr.* 83, 111); from these solutions the oxide crystallises on cooling; in the case of  $\text{HClAq}$  some  $\text{AsCl}_3$  remains in solution, tartaric acid is, however, said to form a salt analogous to tartar emetic. An aqueous solution of  $\text{As}_2\text{O}_3$  slightly reddens litmus, but no acid has been obtained in definite form. The oxide must be regarded as a feebly acid-forming oxide possessing at the same time salt-forming tendencies (*v. ARSENIOUS ACID AND ARSENITES*; and also, *infra*, *Reactions*; especially Nos. 2, 10, and 11; and *Combinations*, No. 2).

**Reactions.**—Arsenious oxide acts both as a reducing and an oxidising agent; it deoxidises nitric, manganic, chromic, hypochlorous, acids, &c., with formation of arsenic acid; it oxidises carbon, sulphur, phosphorus, hydrogen, sodium,

potassium, carbon monoxide, potassium cyanide &c., when heated with these bodies. The oxide in solution is oxidised to arsenic oxide by chlorine, bromine, or iodine, in presence of alkaline bicarbonates; on this fact is based the use of  $\text{As}_2\text{O}_3$  in volumetric analysis. 1. Chlorine passed over the dry oxide at a moderate temperature forms  $\text{AsCl}_3$  (Weber, P. 112, 619); in solution chlorine produces arsenic acid and  $\text{HClAq}$ ; iodine and bromine act similarly in presence of alkaline bicarbonates. 2. Hydrochloric acid forms some  $\text{AsCl}_3$ , but in presence of  $\text{HNO}_3$  or  $\text{KClO}_3$  only  $\text{As}_2\text{O}_3$  is produced. 3. Free oxygen does not oxidise  $\text{As}_2\text{O}_3$  at ordinary temperatures, but if a plate of Pt is partly immersed in solution of  $\text{As}_2\text{O}_3$  in  $\text{HClAq}$  the oxygen coming off from the Pt produces  $\text{As}_2\text{O}_3$  (Berthelot, C. R. 84, 1408). 4. An aqueous solution of  $\text{As}_2\text{O}_3$  heated to  $200^\circ$  with phosphorus yields phosphide of arsenic (Oppenheim, Bl. [2] 1, 163). 5. Na amalgam appears to reduce  $\text{As}_2\text{O}_3$  with production of a solution which acts as an energetic reducer (Fremy, C. R. 70, 61). 6. Phosphorus trichloride reacts at  $110^\circ$ – $130^\circ$  according to the equation  $5\text{As}_2\text{O}_3 + 12\text{PCl}_3 = 2\text{As}_4 + 6\text{P}_2\text{O}_3 + 12\text{AsCl}_3$  (Michaelis, J. Z. 6, 239). 7. Phosphorus pentachloride produces  $\text{AsCl}_3$  and  $\text{POCl}_3$  (Hurtzig a. Geuther, A. 111, 159). 8. When  $\text{As}_2\text{O}_3$  is shaken with ammonia solution, an unstable compound is formed (De Luynes, C. R. 44, 1353). 9. Phosphorous and hypophosphorous acids precipitate arsenic and produce phosphoric acid. 10. Sulphydric acid ( $\text{H}_2\text{S}$ ) passed into an aqueous solution of  $\text{As}_2\text{O}_3$  forms  $\text{As}_2\text{S}_3$  which is ppt. on addition of an acid (v. ARSENIOUS SULPHIDE). 11. Ammonium hydrogen tartrate solution is said to dissolve  $\text{As}_2\text{O}_3$ ; on cooling, crystals of a double salt isomorphous with tartar emetic separate out (Marignac, Ann. M. [5] 15, 288). Pelouze (J. Ch. [3] 6, 63) describes a somewhat similar salt containing K in place of  $\text{NH}_4$ . Neither tartrate has, however, been satisfactorily examined. 12. Heated in a tube with a dry acetate, caecodyl oxide,  $\text{As}(\text{CH}_3)_2\text{O}$ , is produced. 13. Heated with dry alkaline earth oxides or with dry carbonates of the fixed alkalis, an arsenate of the metal is produced along with arsenic which sublimes. 14. The oxide dissolves in hot solutions of the alkalis but most of it pps. again on cooling in the air (v. ARSENIOUS ACID AND ARSENITES). 15. The higher oxidised compounds of many metals are reduced by  $\text{As}_2\text{O}_3$ ; thus  $\text{CuO}$  is reduced to  $\text{Cu}_2\text{O}$ , in presence of alkali. 16. Many metals, e.g. zinc, reduce acid solutions of  $\text{As}_2\text{O}_3$  with pps. of As and formation of  $\text{AsH}_3$ . 17.  $\text{As}_2\text{O}_3$  is reduced by a Cu-Zn couple with formation of  $\text{AsH}_3$  (Gladstone a. Tribe, C. J. 33, 306). 18. Palladium or platinum charged with hydrogen separates As from  $\text{As}_2\text{O}_3$  without formation of  $\text{AsH}_3$  (Gladstone, l.c.). 19. Some metallic salts which act as reducing agents convert the oxide into arsenic; e.g.  $\text{SnCl}_2$  Aq produces  $\text{SnCl}_4$ , As, and  $\text{AsH}_3$  (Kessler, J. 1861, 265). 20. Freshly pnd. ferric hydrate reacts with  $\text{As}_2\text{O}_3$  or with alkaline arsenites to form an insoluble compound, probably arsenite of iron; on this fact is based the use of ferric hydrate as an antidote in cases of arsenic poisoning (v. Bunsen and Berthold, Das Eisenoxydhydrat, ein Gegengift der arsenigen Säure, Göttingen, 1834).

**Combinations.**—1. Fused with arsenic oxides the body  $\text{As}_2\text{O}_3 \cdot \text{As}_2\text{O}_5$  is probably produced (Bloxam, C. J. 18, 62). Other compounds of  $\text{As}_2\text{O}_3$  and  $\text{As}_2\text{O}_5$  are obtained by oxidising  $\text{As}_2\text{O}_3$  by warm  $\text{HNO}_3$  Aq (v. Joly, C. R. 100, 1221). 2. Dissolves in fuming sulphuric acid; on evaporation yields needle-shaped crystals of  $\text{As}_2\text{O}_3 \cdot 4\text{SO}_3$ , which are decomposed by water (Schultz-Shellac, B. 4, 109, gives the formula  $\text{As}_2(\text{SO}_3)_4 \cdot \text{SO}_3$ ). A compound of  $\text{As}_2\text{O}_3$  and  $\text{SO}_3$  was obtained by Schafhäütl (B. J. 22, 113), in the fumes from copper-smelting works in Wales; and by Reich in a canal which carried off the sulphurous acid from a pyrites work near Freiberg (J. pr. 90, 176). 3. By cooling mixed hot aqueous solutions of KI, KBr, or KCl and  $\text{KAsO}_4$ , the compounds  $\text{As}_2\text{O}_3 \cdot \text{KI}$ ,  $\text{As}_2\text{O}_3 \cdot \text{KBr}$ , and  $\text{As}_2\text{O}_3 \cdot \text{KCl}$  are obtained (Rüdorff, B. 18, 1111; v. also Schiff a. Sestini, A. 228, 72). Rüdorff (B. 19, 2678) also describes  $\text{NH}_4\text{AsO}_3$ ,  $\text{NH}_4\text{Br} \cdot \text{As}_2\text{O}_3$ , and  $2\text{NH}_4\text{Cl} \cdot \text{As}_2\text{O}_3$ . Forms a complex series of compounds with  $\text{MoO}_3$  and  $\text{WO}_3$ , and various bases (v. Gibbs, Am. 7, 209 a. 313; C. N. 48, 155).

II. ARSENIC OXIDE.  $\text{As}_2\text{O}_5$ . Mol. w. unknown; not less than that represented by formula. (Arsenic pentoxide, Arsenic anhydride.) S.G. 3.734 (fused oxide). S.V.S. 61.6. H.F. 219,100; H.F. in aqueous solution, 225,400.  $[\text{As}^{5+}\text{O}_4\text{O}^-] = 78,350$  (Th. 2, 236).

**Preparation.**—Not produced by heating arsenic in air or oxygen. If arsenic or arsenious oxide is digested with  $\text{HNO}_3$  Aq, or with a mixture of 1 part  $\text{HClAq}$  and 12 parts  $\text{HNO}_3$  Aq in a retort, or if chlorine is led into a warm solution of  $\text{As}_2\text{O}_3$ , arsenic acid,  $\text{H}_3\text{AsO}_4$ , is produced and may be obtained as crystals by cooling a concentrated solution. When this acid is heated to low redness the anhydride  $\text{As}_2\text{O}_5$  is produced.

**Properties.**—A white solid which slowly absorbs moisture from the air with formation of  $\text{H}_3\text{AsO}_4$  Aq. Slowly but completely dissolves in water forming  $\text{H}_3\text{AsO}_4$  Aq. Heated above low redness it yields  $\text{As}_2\text{O}_3$  and O.

**Reactions.**—1. Heated with charcoal, many metals, or potassium cyanide, it yields As. 2. Heated with conc. hydrochloric acid it yields  $\text{AsCl}_3$ ; with  $\text{HCl}$  gas even in the cold the same product is obtained (Souchay, Fr. 1, 189; Mayrhofer, A. 158, 326). 3. Reacts with phosphorus pentachloride thus:  $\text{As}_2\text{O}_5 + 5\text{PCl}_5 = 5\text{POCl}_3 + 2\text{Cl}_2 + 2\text{AsCl}_3$  (Hurtzig a. Geuther, A. 3, 159). 4. According to Michaelis (J. Z. 6, 239), the oxide is not acted on by  $\text{POCl}_3$  even at  $200^\circ$ . 5. Reduced in aqueous solution by nascent hydrogen with formation of  $\text{AsH}_3$ ; but if chlorides are present only a trace of  $\text{AsH}_3$  is produced according to Bloxam (C. J. 15, 56). 6. Stannous chloride, in the cold, produces stannous pyroarsenate and arsenite, in warm solutions produces arsenic and  $\text{AsH}_3$  (Schiff, J. 1861, 278; Kessler, ibid. 265). 7. With water it reacts to produce arsenic acid,  $\text{H}_3\text{AsO}_4$  Aq. Joly (C. R. 106, 1662) describes a hydrate  $\text{As}_2\text{O}_5 \cdot 4\text{H}_2\text{O}$ . Arsenic oxide reacts as a strongly acid-forming oxide and exhibits no tendency to form corresponding salts by reactions with acids (v. e.g. reaction with  $\text{HClAq}$ ). 8. Forms a large series of compounds with  $\text{MoO}_3$  or  $\text{WO}_3$ , and bases (v. Gibbs, Am. 7, 209 a. 313; C. N. 48, 155).

**Arsenic, oxybromides of.**  $\text{AsOBr}$  (*Bromarsenious acid*); and  $\text{?As}_2\text{O}_2\text{Br}_2$ . Mol. w. unknown, not less than represented by above formulæ.

**Formation.**— $\text{AsOBr}$  is produced by the action of  $\text{H}_2\text{O}$  in limited quantity on  $\text{AsBr}_3$ .

**Preparation.**—Arsenious oxide is dissolved in molten  $\text{AsBr}_3$ ; the dark viscid liquid which results is distilled till it becomes rather thick, and is then cooled to  $150^\circ$  whereat it separates into two layers, the upper of which contains the oxybromide  $\text{AsOBr}$ , and the lower probably contains the other oxybromide  $\text{As}_2\text{O}_2\text{Br}_2$  (Wallace, *P. M.* [4] 17, 261).

**Properties.**—Brown, waxy, solid. Decomposed by heat to  $\text{AsBr}_3$  and  $\text{As}_2\text{O}_3$ .

**Combinations.**—With water; a hydrate of arsenic oxybromide,  $2\text{AsOBr} \cdot 3\text{H}_2\text{O}$  is obtained as thin white pearly crystals by placing a cold concentrated aqueous solution of  $\text{AsBr}_3$ , containing  $\text{HBr}$ , over sulphuric acid (Wallace, *l.c.*). If the solution of  $\text{AsBr}_3$  in  $\text{HBr}$  is boiled, another compound, said to have the composition  $4\text{AsBr}_3 \cdot 11\text{As}_2\text{O}_3 \cdot 21\text{H}_2\text{O}$ , separates out (Wallace, *l.c.*).

**Arsenic, oxychlorides of.**  $\text{AsOCl}$  (*Chlorarsenious acid*); and  $\text{As}_2\text{O}_2\text{Cl}_2$ . Mol. ws. unknown, not less than represented by above formulæ.

**Formation.**—When  $\text{AsCl}_3$  is mixed with less than sufficient water to completely decompose it,  $\text{AsOCl}$  is formed.

**Preparation of  $\text{AsOCl}$ .**—By distilling until frothing begins the liquid obtained (a) by dissolving  $\text{As}_2\text{O}_3$  in boiling  $\text{AsCl}_3$  in the proportion  $\text{As}_2\text{O}_3 : 2\text{AsCl}_3$ , or (b) by leading dry  $\text{HCl}$  gas over dry warm  $\text{As}_2\text{O}_3$  until almost the whole of the latter has been changed to  $\text{AsCl}_3$ , and allowing to cool.

**Properties of  $\text{AsOCl}$ .**—Obtained as above, it is a hard, translucent, slightly-fuming solid which slowly absorbs oxygen from the air (Wallace, *P. M.* [4] 16, 358; Hantzsch & Geuther, *A.* 111, 172).

**Combinations.**—1. A solution of  $\text{AsCl}_3$  in conc.  $\text{HCl}$ aq mixed with solid ammonium chloride, and allowed to stand, deposits crystals of  $\text{AsOCl} \cdot \text{H}_2\text{O}$ , but after some days white fibrous needles are formed, which, when dried over  $\text{H}_2\text{SO}_4$ , have the composition  $\text{AsOCl} \cdot 2\text{NH}_4\text{Cl}$ .—2. With water; a hydrate of  $\text{AsOCl}$ , having the composition  $\text{AsOCl} \cdot \text{H}_2\text{O}$  ( $= \text{As}(\text{OH})_2\text{Cl}$ ) is obtained by adding water to  $\text{AsCl}_3$  in about the proportion  $8\text{H}_2\text{O} : \text{AsCl}_3$  and allowing to stand for some days. The hydrate forms small star-like crystals (Wallace, *l.c.*).

$\text{As}_2\text{O}_2\text{Cl}_2$  is said to be obtained, as a hard, glass-like solid, when  $\text{AsOCl}$  is heated until  $\text{As}_2\text{O}_3$  begins to sublime from it (about  $218^\circ$ ) (Wallace, *l.c.*).

**Arsenic, oxyiodide of.**  $\text{AsOI} \cdot \text{As}_2\text{O}_3$ . Mol. w. unknown. Produced in thin pearly laminae, according to Wallace (*P. M.* [4] 17, 122) by slowly cooling a hot conc. solution of  $\text{AsI}_3$  in  $\text{H}_2\text{O}$ , drying between filter paper, and then over  $\text{H}_2\text{SO}_4$ .

**Arsenic, pentafluoride of; double compounds containing.** No gaseous compound of arsenic of the type  $\text{AsX}_5$ , where X is a monovalent atom or atomic group, has yet been obtained. Solid compounds are, however, known, one of the constituents of which seems to be the group  $\text{AsF}_2$ . The following are described by Marignac

(*A.* 145, 287):—1. *Potassic-arsenic fluoride*,  $2(\text{KF} \cdot \text{AsF}_2) \cdot \text{H}_2\text{O}$ ; formed in well-developed rhombic prisms by dissolving potassium arsenate in much hydrofluoric acid.—2. *Potassic-arsenic oxyfluoride*,  $\text{KF} \cdot \text{AsOF}_2 \cdot \text{H}_2\text{O}$ ; formed in acute rhombic plates by repeated evaporation of the solution from which compound No. 1 is obtained, or by dissolving potassium arsenate in a small quantity of  $\text{HFAq}$ .—3. *Dipotassic-arsenic fluoride*,  $2\text{KF} \cdot \text{AsF}_2 \cdot 11\text{H}_2\text{O}$ ; large, lustrous, rhombic prisms, obtained by adding  $\text{KFAq}$  to a solution in  $\text{HFAq}$  of either of the preceding salts, and evaporating.—4. *The double salt*  $4\text{KF} \cdot \text{AsF}_2 \cdot \text{AsOF}_2 \cdot 3\text{H}_2\text{O}$  is said to be produced when a solution in  $\text{HFAq}$  of salt No. 3 is repeatedly evaporated.

**Arsenic, phosphide of, v. ARSENIC, Combinations, No. 8.**

**Arsenic, selenides of, and Seleno-sulphides of, v. ARSENIC, Combinations, No. 7.**

**Arsenic, sulphides of.** (In connection with these compounds v. art. SULPHIDES.) Three sulphides of arsenic are known;  $\text{As}_2\text{S}_3$ ,  $\text{As}_2\text{S}_5$ , and  $\text{As}_4\text{S}_6$ . None of these has been gasified, hence the formulæ do not necessarily represent molecules of the compounds.  $\text{As}_2\text{S}_3$  and  $\text{As}_2\text{S}_5$  occur native as *Realgar* and *Orpiment* respectively. The two sulphides  $\text{As}_2\text{S}_3$  and  $\text{As}_2\text{S}_5$  are salt-forming; they dissolve in alkali sulphides with production of thio-arsenates  $\text{M}_2\text{AsS}_3$  &c., or thio-arsenates  $\text{M}_2\text{AsS}_5$  &c. (*v. infra*). The disulphide,  $\text{As}_4\text{S}_6$ , is not salt-forming; Berzelius's statement that it combines with various metallic sulphides has been shown to be erroneous (Nilson, *B.* 4, 989).

**I. ARSENIC DISULPHIDE.**  $\text{As}_2\text{S}_3$  (*Realgar*, *Red orpiment*, *Ruby sulphur*). S.G. 3.4–3.6. H. 1.5–2. Mol. w. unknown. S.V.S. 61.1.

**Occurrence.**—Native, as *Realgar*, accompanying ores of silver and lead, &c.

**Preparation.**—1. By heating together As and S, or  $\text{As}_2\text{S}_3$  with As, in the proper proportions.—2. By heating  $\text{As}_2\text{O}_3$  with S, in the proportion  $\text{As}_2\text{O}_3 : 7\text{S}$ , repeatedly subliming the mass from end to end of a glass tube in a stream of  $\text{CO}_2$  (Nilson, *J. pr.* [2] 8, 89).—3. By heating  $\text{As}_2\text{S}_5$  with  $\text{NaHCO}_3\text{aq}$  in a closed tube to  $150^\circ$ ; crystals are thus obtained  $\frac{1}{2}$  mm. long (Sénarmont, *A. Ch.* [3] 82, 129).—4. On the large scale, impure, containing  $\text{As}_2\text{O}_3$  (Hausmann, *A.* 74, 196), by subliming a mixture of arsenical pyrites and iron pyrites.

**Properties.**—Occurs native in monoclinic prisms,  $a:b:c = 1.32:1:4.86$ ;  $\alpha = 85^\circ 16'$ ; orange-red, more or less translucent, resinous lustre, conchoidal fracture. Pure  $\text{As}_2\text{S}_3$  is transparent, ruby colour, easily fusible, and crystalline after fusion; it burns in the air with a blue flame forming  $\text{SO}_2$  and  $\text{As}_2\text{O}_3$ . It is used as a pigment, also in pyrotechny.

**Reactions.**—1. *Nitric acid* oxidises  $\text{As}_2\text{S}_3$  to  $\text{H}_2\text{AsO}_4$ ,  $\text{H}_2\text{SO}_4\text{aq}$ ,  $\text{H}_2\text{SO}_4\text{aq}$ , and S.—2. Heated in a current of chlorine,  $\text{S}_2\text{Cl}_2$  and  $\text{AsCl}_3$  are produced (Nilson, *J. pr.* [2] 12, 295; 13, 1).—3. Heated in hydrogen, As and  $\text{H}_2\text{S}$  are formed (N.).—4. Solution of potash partially dissolves  $\text{As}_2\text{S}_3$ , with formation of  $\text{As}_2\text{S}_5$ , which then forms  $\text{KAsS}_3\text{aq}$ , and production of As (N.).—5. It is slightly soluble in solutions of the alkali-metal sulphides.—6. It is electrolysed to As and S by a powerful battery (Lapshin-

Tichonowitsch, O. C. [2] 6, 613).—7. Heated with iodine, the compound  $\text{As}_2\text{S}_3 \cdot \text{AsI}_3$  (=AsSI) is produced (Schneider, *J. pr.* [2] 28, 486).

II. ARSENIC TRISULPHIDE.  $\text{As}_2\text{S}_3$  (Arsenious sulphide, Sulpharsenious anhydride, Orpiment, Yellow sulphide of arsenic). Mol. w. unknown. S.G. 3.46–3.48. S.V.S. 70.9.

Occurrence.—Native as Orpiment.

Formation.—1. By heating to  $70^\circ$ – $80^\circ$  a solution of  $\text{Na}_2\text{CO}_3$  saturated with  $\text{As}_2\text{S}_3$  (Nilson, *J. pr.* [2] 12, 295; 13, 1).—2. Impure, commercial, by subliming together 7 parts powdered  $\text{As}_2\text{O}_3$  with 1 part S.

Preparation.—1. By subliming together As and S in the proper proportions. 2. By saturating  $\text{As}_2\text{O}_3$  with  $\text{H}_2\text{S}$  a little  $\text{HClAq}$  being added. If no mineral acid is added the  $\text{As}_2\text{S}_3$  produced remains in solution in a colloidal form (Schneider, *J. pr.* [2] 25, 431).

Properties.—Occurs native in trimetric prisms (a:b:c = 603:1:674) translucent, lemon- or slightly orange-yellow. Prepared in the wet way it forms a lemon-yellow powder which becomes darker when heated. Melts easily and volatilises at a higher temperature. When  $\text{H}_2\text{S}$  is passed into  $\text{As}_2\text{O}_3$   $\text{As}_2\text{S}_3$  is formed but remains in solution in colloidal form; a saturated solution contains 34.16 p.c.  $\text{As}_2\text{S}_3$ ; it is slowly decomposed on standing, but may be boiled without precipitation of  $\text{As}_2\text{S}_3$ ; bone char removes all the  $\text{As}_2\text{S}_3$  from solution; most acids and many salts precipitate  $\text{As}_2\text{S}_3$  (Schneider, *J. pr.* [2] 25, 431). Used as a pigment, also as a reducing agent in dyeing, also as a depilatory.

Reactions.—1. Long-continued action of hot water produces  $\text{H}_2\text{S}$  and  $\text{As}_2\text{O}_3$   $\text{As}_2\text{O}_3$  according to Field (C. N. 3, 114).—2. Dilute acids do not act on  $\text{As}_2\text{S}_3$ ; conc.  $\text{HClAq}$  produces  $\text{AsCl}_3$ ; conc.  $\text{HNO}_3$   $\text{As}_2\text{S}_3$  produces  $\text{H}_2\text{SO}_4$ ,  $\text{As}_2\text{O}_3$ , and  $\text{H}_2\text{AsO}_4$ . 3. Fused with potassium-hydrogen sulphate,  $\text{SO}_2$  is evolved, and  $\text{KHA}_2\text{O}_4$  and  $\text{K}_2\text{SO}_4$  remain. 4. Chlorine acts readily, a brown liquid is formed said to be a chlorosulphide of As (H. Rose); heated with chlorine,  $\text{AsCl}_3$  is produced (Ludwig, *Ar. Ph.* 97, 23).—5. Passed over hot iron, silver, &c., sulphide of the metal is formed, and arsenic which partially alloys with the metal.—6. Passed over red-hot lime, sulphide and arsenate of calcium, and arsenic are produced.—7. Heated with sodium or potassium carbonate, a mirror of As is obtained, along with arsenate and thioarsenate of the alkali metal; if the mixture is heated in hydrogen the arsenate is reduced (Rose, *P.* 90, 565).—8. Heated with an alkaline carbonate and charcoal or potassium cyanide, a mirror of As is obtained; according to Fresenius (*A.* 49, 287), the whole of the As in the  $\text{As}_2\text{S}_3$  is thus obtained; according to Rose (*Ph. C.* 1853, 594), some of the As forms thioarsenate (KONS being also produced) which is not reduced. No mirror of As is obtained (Rose) if  $\text{As}_2\text{S}_3$  is mixed with excess of S and heated with KCN; the presence of an easily reduced metal is also said to prevent the formation of As, because the As alloys with the metal. If the mixture of  $\text{As}_2\text{S}_3$  with  $\text{Na}_2\text{CO}_3$  (or  $\text{K}_2\text{CO}_3$ ) and KCN is heated in hydrogen, the whole of the arsenic is obtained as metal (comp. Rose, *P.* 90, 565, with Nilson, *A.* 49, 287).—9.  $\text{As}_2\text{S}_3$  readily dissolves in cold

aqueous potash, soda, or ammonia, forming an arsenite and a thioarsenite; thus:

on adding an acid to the solution the whole of the As is precipitated as  $\text{As}_2\text{S}_3$ ; thus:

If oxide of Ag or Pb is added to a solution of  $\text{As}_2\text{S}_3$  in  $\text{NH}_3$   $\text{Aq}$  and the solution is boiled, the whole of the S is precipitated as  $\text{Ag}_2\text{S}$  or  $\text{PbS}$ , and Ag or Pb arsenite remains in solution. 10. When  $\text{As}_2\text{S}_3$  is boiled with a solution of sodium or potassium carbonate,  $\text{As}_2\text{S}_3$  is precipitated,  $\text{CO}_2$  and  $\text{H}_2\text{S}$  are evolved, and the solution contains the following salts,  $\text{Na}_2\text{S} \cdot 3\text{As}_2\text{S}_3$ ;  $\text{Na}_2\text{O} \cdot 2\text{As}_2\text{S}_3 \cdot \text{O}_2$ ;  $\text{Na}_2\text{AsS}_4$ ;  $\text{Na}_2\text{HAsO}_4$ ;  $\text{NaHCO}_3$ ; (Nilson, *J. pr.* [2] 14, 1, 145).—11.  $\text{As}_2\text{S}_3$  is easily soluble in a hot solution of potassium-hydrogen sulphite; thus,  $2\text{As}_2\text{S}_3 + 16\text{KHSO}_3 \cdot \text{Aq} = 4\text{KAsO}_2 \cdot \text{Aq} + 6\text{K}_2\text{S}_2\text{O}_8 \cdot \text{Aq} + 7\text{SO}_2 \cdot \text{Aq} + 3\text{S} + 8\text{H}_2\text{O}$ .

Combinations.— $\text{As}_2\text{S}_3$  acts as a salt-forming sulphide, or anhydride of a thio-acid; it combines with the sulphides of the alkali and alkaline earth metals, and with some metallic hydrosulphides, to form thioarsenites (q.v. under ARSENIC, THIO-ACIDS OF). The following are the typical reactions:

1.  $\text{As}_2\text{S}_3 + \text{K}_2\text{SAq} = 2(\text{AsS} \cdot \text{SKAq})$ .
2.  $\text{As}_2\text{S}_3 + 6\text{NH}_4\text{ISAq} = 2(\text{As} \cdot (\text{SNH})_3 \cdot \text{Aq}) + 3\text{H}_2\text{S}$ .
3.  $\text{As}_2\text{S}_3 + 2(\text{NH}_4)_2\text{SAq} = \text{As}_2\text{S}(\text{SNH})_4 \cdot \text{Aq}$ .

III.—ARSENIC PENTASULPHIDE.  $\text{As}_2\text{S}_5$  (Persulphide of Arsenic). Mol. w. unknown.

Preparation.—1. By melting As with considerable excess of S, a thin, transparent, liquid is obtained which solidifies to an elastic mass, and after some time becomes hard; if this hard solid is powdered and treated with  $\text{NH}_3$   $\text{Aq}$  a solution of  $\text{As}_2\text{S}_5$  is obtained from which the sulphide is thrown down on addition of  $\text{HClAq}$  (Gélin, *A. Ch.* [4] 30, 114).—2. A solution of  $\text{Na}_2\text{S}$  is digested with  $\text{As}_2\text{S}_3$  and enough S to form  $\text{As}_2\text{S}_5$ , on evaporating and cooling large crystals of  $2\text{Na}_2\text{AsS}_5 \cdot 15\text{H}_2\text{O}$  are obtained (Rammelsberg, *P.* 52, 249; 90, 40); when  $\text{HClAq}$  is added to a solution of this salt,  $\text{As}_2\text{S}_5$  is precipitated and  $\text{H}_2\text{S}$  is evolved (Fuchs, *Nr.* 1, 189; Flückiger, *Vierteljahrsschr. pr. Pharm.* 12, 330; Eckert, *ibid.* 13, 357). The product of the action of  $\text{H}_2\text{S}$  on  $\text{H}_2\text{AsO}_4$  is not  $\text{As}_2\text{S}_5$ , as was once supposed, but is a mixture of  $\text{As}_2\text{S}_3$  and S ( $2\text{H}_2\text{AsO}_4 \cdot \text{Aq} + 2\text{H}_2\text{S} = \text{As}_2\text{O}_3 \cdot \text{Aq} + 5\text{H}_2\text{O} + \text{S}$ ;  $\text{As}_2\text{O}_3 \cdot \text{Aq} + 3\text{H}_2\text{S} = \text{As}_2\text{S}_3 + 3\text{H}_2\text{O}$ ) (v. Ludwig, *Ar. Ph.* [2] 97, 32; also H. Rose, *P.* 107, 186).

Properties.—A yellow powder, easily fusible; may be sublimed in a stream of a gas which does not act on it.

Reactions.—1. Heated in a stream of hydrogen, it is reduced to metallic As, and  $\text{H}_2\text{S}$ . 2. Dissolves easily in ammonia, potash, and soda solutions, with production of thioarsenate, and arsenate, of the alkali metal.—3. Dissolves easily in solutions of alkali sulphides, forming thioarsenates. The sulphide  $\text{As}_2\text{S}_5$  behaves as a salt-forming compound, or as the anhydride of thioarsenic acid; the salts which are generally formed directly from it are pyro-thioarsenates  $\text{M}_2\text{As}_2\text{S}_5$ ; these yield two other series of salts, viz. ortho-thioarsenates  $\text{MAsS}_4$ , and meta-thioarsenates  $\text{MAsS}_3$ , (v. ARSENIC, THIO-ACIDS OF).

**Arsenic, sulpho-acids of, v. ARSENIO THIO-ACIDS OF.**

**Arsenic, sulpho- (or thio-) bromide of.**  $\text{AsS}_2\text{Br}_2$  (=  $\text{AsSBr} \cdot \text{SBr}_2$ ). Mol. w. unknown. [ $-17^\circ$ ]. Dark red crystals deposited at  $-18^\circ$  on addition of a small quantity of powdered As to a solution of S in Br in ratio  $\text{S}:\text{Br}_2$ ; decomposed by water into  $\text{As}_2\text{O}_3$ ,  $\text{HBr}$ , and S (Hannay, *C. J.* 33, 291).

**Arsenic, sulpho- (or thio-) iodide of.**  $\text{AsSI}$ . Said to be formed by the mutual action of  $\text{As}_2\text{S}_3$  and I (Schneider, *J. pr.* [2] 23, 486).

**Arsenic, sulphhydrates (or hydrosulphides) of.** Only one compound As, S, and H is definitely known,  $\text{AsS}(\text{SH})_3$ ; v. *Thioarsenic acids* under ARSENIO, THIO-ACIDS OF (v. also the art. HYDROSULPHIDES).

**Arsenic, tellurides of, v. ARSENIO, Combinations, No. 6.**

**Arsenic, thio-acids of.** (In connection with these compounds v. the art. HYDROSULPHIDES.) Arsenious sulphide,  $\text{As}_2\text{S}_3$ , dissolves in alkalis or alkali sulphides to form salts, and from these other salts are obtained by double decomposition. The sulphide  $\text{As}_2\text{S}_3$  may be regarded as the anhydride of three thio-acids  $\text{AsS}(\text{SH})_2$ ,  $\text{As}(\text{SH})_3$ , and  $\text{As}_2\text{S}(\text{SH})_2$ , corresponding to the three hypothetical oxy-acids (v. ARSENIOUS ACID); none of these acids is known, all attempts to prepare them having resulted only in the production of  $\text{As}_2\text{S}_3$  and  $\text{H}_2\text{S}$ , but thio- or sulph-arsenites are known belonging to the three types,  $\text{MAAsS}_2$ ,  $\text{M}_2\text{AsS}_3$ , and  $\text{M}_3\text{As}_4\text{S}_7$ . The more important of these salts are described below. Arsenic pentasulphide,  $\text{As}_2\text{S}_5$ , dissolves in alkalis and alkali sulphides to form salts from which other salts are obtained (v. *infra*). According to Nilson (*J. pr.* [2] 14, 1, 145) the pp. obtained by adding dilute  $\text{HCl}$  to a solution of  $\text{Na}_2\text{AsS}_5$  (v. ARSENIO PENTASULPHIDE, Preparation of) has the composition of ortho-thio-arsenic acid  $\text{H}_2\text{AsS}_4$  (=  $\text{AsS}(\text{SH})_3$ ); no other thio-arsenic acid is known, but the salts may be divided into three classes, analogous to the arsenates, viz.: *pyro-thio-arsenates*  $\text{M}_2\text{As}_2\text{S}_5$  (hypothetical acid =  $\text{H}_2\text{As}_2\text{S}_5$ ), *meta-thio-arsenates*  $\text{MAsS}_4$  (hypothetical acid =  $\text{HAsS}_4$ ), and *ortho-thio-arsenates*  $\text{M}_3\text{As}_4\text{S}_7$  (acid (?)  $\text{H}_3\text{As}_4\text{S}_7$ ).

**I. THIO-ARSENITES.** As already stated, no thio-arsenious acid is known. The salts which have been examined belong for the most part to the type  $\text{MAsS}_4$ ; they are produced either by the direct union of  $\text{As}_2\text{S}_3$  with metallic hydrosulphides, e.g.  $\text{LiAsS}_4$ , or by ordinary double decomposition of  $(\text{NH}_4)_2\text{As}_2\text{S}_5$  by solutions of metallic salts, e.g.  $\text{PhAsS}_4$ . A few salts belonging to the forms  $\text{MAAsS}_2$  and  $\text{M}_2\text{AsS}_3$  are also known, e.g.  $\text{KAsS}_2$  and  $\text{K}_2\text{AsS}_3$ ; they are formed by the action of alkali sulphides on  $\text{As}_2\text{S}_3$  (comp. reactions given for ARSENIO TRISULPHIDE, p. 315). The thio-arsenites of the alkali and alkaline earth metals and of magnesium are soluble in water, but the solutions are decomposed on boiling, the others are insoluble in water. Most of these salts give off all their sulphur when strongly heated out of contact with air. These salts have been chiefly investigated by Berzelius (v. *Gm.* 4, 275).

Only those salts which have been fairly satisfactorily examined are mentioned in the following brief account:—

**Ammonium thio-arsenites.**  $(\text{NH}_4)_2\text{As}_2\text{S}_5$  is obtained by dissolving  $\text{As}_2\text{S}_3$  in  $(\text{NH}_4)_2\text{SAq}$  and adding alcohol; if  $\text{NH}_4\text{HSAq}$  is added before precipitating by alcohol the salt obtained has the composition  $(\text{NH}_4)_2\text{As}_2\text{S}_5$ .

**Barium thio-arsenites.**  $\text{Ba}_2\text{As}_2\text{S}_5$  is obtained as a pasty brownish-red very soluble mass by digesting  $\text{As}_2\text{S}_3$  with  $\text{BaS}_2\text{H}_2\text{Aq}$ ; from the solution alcohol throws down  $\text{Ba}_2(\text{AsS}_2)_2$ .

**Calcium thio-arsenites.** The salt  $\text{Ca}_2(\text{AsS}_2)_2$  is obtained as crystals by digesting  $\text{As}_2\text{S}_3$  with milk of lime and allowing the solution to evaporate; from the brownish mother-liquor alcohol precipitates white  $\text{Ca}_2(\text{AsS}_2)_2 \cdot 15\text{H}_2\text{O}$ .

**Lithium thio-arsenites.** Closely resemble the potassium salts (q.v.).

**Potassium thio-arsenites.** The salt  $\text{KAsS}_2$  may be obtained in solution by dissolving  $\text{As}_2\text{S}_3$  in  $\text{K}_2\text{SAq}$ , but this solution decomposes on evaporation; in the solid form by heating  $\text{KAsS}_2$  or by fusing  $\text{As}_2\text{S}_3$  with  $\text{K}_2\text{CO}_3$ . By adding alcohol to a solution of  $\text{As}_2\text{S}_3$  in  $\text{KSAq}$ , a white pp. of  $\text{K}_3\text{AsS}_4$  is obtained. All these salts readily undergo change in aqueous solutions. Berzelius describes several other more or less indefinite bodies as potassium thio-arsenites.

**Sodium thio-arsenites.** Closely analogous to the potassium salts.

The following thio-arsenites seem also to exist; they are generally obtained from  $(\text{NH}_4)_2\text{As}_2\text{S}_5$  by double decomposition:— $(\text{BiS})_2\text{As}_2\text{S}_5$ ;  $\text{CeAs}_2\text{S}_5$ ;  $\text{CdAs}_2\text{S}_5$ ;  $\text{CoAs}_2\text{S}_5$ ;  $\text{CuAs}_2\text{S}_5$ ;  $\text{FeAs}_2\text{S}_5$ ;  $\text{Au}(\text{AsS}_2)_3$ ;  $\text{MgAs}_2\text{S}_5$ ;  $\text{MnAs}_2\text{S}_5$ ;  $\text{HgAs}_2\text{S}_5$ ;  $\text{Hg}(\text{AsS}_2)_2$ ;  $\text{NiAs}_2\text{S}_5$ ;  $\text{SnAs}_2\text{S}_5$ ;  $\text{SnAs}_2\text{S}_5$ ;  $\text{PtAs}_2\text{S}_5$ ;  $\text{AgAs}_2\text{S}_5$ ;  $(\text{U})_2\text{As}_2\text{S}_5$ ;  $\text{ZnAs}_2\text{S}_5$ . Thio-arsenites of chromium, molybdenum, and zirconium, seem also to exist.

**II. THIO-ARSENATES.** As already stated, it is probable that ortho-thio-arsenic acid  $\text{H}_2\text{As}_4$  has been prepared. The thio-arsenates may be divided into three classes, of which the three potassium salts are representatives:  $\text{KAsS}_2$ ,  $\text{K}_2\text{AsS}_3$ , and  $\text{KAsS}_4$ . The thio-arsenates are obtained: 1. By digesting  $\text{As}_2\text{S}_3$  with solutions of the alkali sulphides, on cooling some  $\text{As}_2\text{S}_3$  is precipitated.—2. By dissolving  $\text{As}_2\text{S}_3$  in solutions of alkali-polysulphides.—3. By precipitating solutions of arsenates by  $\text{H}_2\text{S}$ , or by  $(\text{NH}_4)_2\text{SAq}$ ; in the latter case the liquids must be boiled to remove  $\text{NH}_3$ .—4. By fusing  $\text{As}_2\text{S}_3$  with alkali carbonates.—5. By dissolving  $\text{As}_2\text{S}_3$  in  $\text{KOH}$  or  $\text{NaOH}$  aq; arsenate is formed as well as thio-arsenate. The thio-arsenates of the alkali metals are yellow or red, very soluble in water, crystallisable, fairly stable, compounds; their aqueous solutions are slowly decomposed by exposure to air. The other thio-arsenates are more easily decomposed; those of the heavy metals are insoluble in water; they are best prepared by decomposing the solution of an alkali thio-arsenate by a solution of a salt of the metal. Soluble thio-arsenates are decomposed by  $\text{HCl}$  aq with precipitation of  $\text{As}_2\text{S}_3$ . The salts obtained by the methods enumerated are usually *pyro-thio-arsenates*  $\text{M}_2\text{As}_2\text{S}_5$ ; the *meta-* and *ortho-* salts are produced from these, very frequently by the action of alcohol on their solutions; alcohol usually precipitates an *ortho-* salt and leaves a *meta-* salt in solution. The *ortho-* salts are frequently crystalline; most of the others are

**amorphous.** Heated in absence of air, most thio-arsenates yield thio-arsenites, and then  $\text{As}_2\text{S}_3$  which sublimes, and a metallic sulphide which remains; some, however, are unchanged by heat alone, e.g.  $\text{M}_3\text{AsS}_4$  where  $\text{M} = \text{Li}, \text{K}, \text{Na}$ . Heated in air, the thio-arsenates, as a class, give off  $\text{As}_2\text{S}_3$  and  $\text{As}_2\text{O}_3$ , and leave a sulphate in the cases of alkaline salts, or an oxide in the cases of salts of heavy metals. The thio-arsenates have been chiefly investigated by Berzelius (*v. Gm.* 4, 275); also by Nilson (*J. pr.* [2] 12, 295; 13, 1).

The following are the thio-arsenates which have been fairly well investigated:—

**Ammonium thio-arsenates.** The *pyro*-salt  $(\text{NH}_4)_3\text{As}_2\text{S}_5$  has not been obtained as a solid: a solution of  $\text{As}_2\text{S}_3$  in  $(\text{NH}_4)_2\text{SAq}$  probably contains this salt, it is decomposed on evaporation; alcohol precipitates the *ortho*-salt  $(\text{NH}_4)_3\text{AsS}_4$  in white prismatic crystals, while the *meta*-salt  $\text{NH}_4\text{AsS}_4$  remains in solution.

**Barium thio-arsenates.** A solution of  $\text{BaHAsO}_4$  is decomposed by  $\text{H}_2\text{S}$ , but the pure *pyro*-thio-arsenate,  $\text{Ba}_3\text{As}_2\text{S}_5$ , has not been obtained; this solution is decomposed by alcohol into  $\text{Ba}_4(\text{AsS}_4)_3$  which precipitates, and  $\text{Ba}(\text{AsS}_4)_2$  which remains in solution.

**Magnesium thio-arsenates.** The *pyro*-salt  $\text{Mg}_3\text{As}_2\text{S}_5$  is a yellow solid, very soluble in water; by adding  $\text{Mg}(\text{SH})_2\text{Aq}$  to this solution until  $\text{H}_2\text{S}$  ceases to come off, and evaporating *in vacuo*, crystals of  $\text{Mg}_4(\text{AsS}_4)_3$  are obtained; alcohol decomposes this salt, dissolving out  $\text{Mg}_2\text{As}_2\text{S}_5$ .

**Potassium thio-arsenates.** The *pyro*-salt,  $\text{K}_3\text{As}_2\text{S}_5$ , is best obtained by treating  $\text{K}_2\text{HAsO}_4\text{Aq}$  with  $\text{H}_2\text{S}$  and evaporating *in vacuo*; it forms a yellow viscid mass which liquefies on exposure to the air and then crystallises in rhombic plates. By adding alcohol to a conc. solution of this salt an oily liquid is obtained which crystallises when warmed giving  $\text{K}_3\text{AsS}_4$ , and  $\text{KAsS}_4$  remains in solution. A salt containing both sulphur and oxygen,  $\text{AsSO}_4\text{OK.H}_2\text{O}$  is described by Bouquet and Cloez (*A. Ch.* [3] 13, 44), produced by the action of  $\text{H}_2\text{S}$  on cold saturated  $\text{K}_2\text{HAsO}_4\text{Aq}$ ; it may perhaps be regarded as a double compound of the hypothetical oxysulphide  $\text{As}_2\text{S}_4\text{O}_2$  with  $\text{K}_2\text{O}$ , but the data are very meagre.

**Sodium thio-arsenates.** The *ortho*-salt  $2\text{Na}_2\text{AsS}_4.15\text{H}_2\text{O}$  is obtained in large white, or yellowish, monoclinic prisms, by digesting  $\text{Na}_2\text{SAq}$  with  $\text{As}_2\text{S}_3$ , or with  $\text{As}_2\text{S}_5$  and sufficient  $\text{S}$  to form  $\text{As}_2\text{S}_5$ , and allowing to crystallise (Fresenius, *Fr.* 1, 192). The same salt is also obtained by decomposing  $\text{Na}_2\text{HAsO}_4\text{Aq}$  by  $\text{H}_2\text{S}$ , and adding alcohol to the solution; according to the conditions under which this liquid is allowed to crystallise, crystals of varying form and somewhat varying appearance are obtained (Berzelius). The crystals are not dehydrated in dry air, but when slowly heated the salt may be obtained without water of crystallisation. It is doubtful whether the *meta*- and *pyro*-thio-arsenates have been obtained; the solution from which the *ortho*-salt is thrown down by alcohol probably contains  $\text{NaAsS}_4$ , and the solution before alcohol is added probably contains  $\text{Na}_2\text{As}_2\text{S}_5$ . The double thio-arsenate  $\text{Na}_2(\text{NH}_4)_2(\text{AsS}_4)_2$  is also described by Berzelius (*l.c.*).

Besides the above salts, the following thio-arsenates seem to have been obtained in fairly definite forms:  $\text{Ca}_3\text{As}_2\text{S}_5$ ,  $\text{Ca}_4(\text{AsS}_4)_3$ ;  $\text{Ce}_3\text{As}_2\text{S}_5$ ,  $\text{Ce}_4(\text{AsS}_4)_3$ ;  $\text{Co}_3(\text{As}_2\text{S}_5)_2$ ,  $\text{Co}_4(\text{As}_2\text{S}_5)_3$ ;  $\text{Au}(\text{AsS}_4)_2$ ;  $\text{Fe}_3(\text{As}_2\text{S}_5)_2$ ,  $\text{Fe}_4(\text{As}_2\text{S}_5)_3$ ;  $\text{Pb}_3\text{As}_2\text{S}_5$ ,  $\text{Pb}_4(\text{AsS}_4)_3$ ;  $\text{Mn}_2\text{As}_2\text{S}_5$ ;  $\text{Hg}_2\text{As}_2\text{S}_5$ ,  $\text{Hg}_4\text{As}_2\text{S}_5$ ;  $\text{Ag}_3\text{As}_2\text{S}_5$ ,  $(\text{US})\text{As}_2\text{S}_5$ . Thio-arsenates of  $\text{Sb}$ ,  $\text{Be}$ ,  $\text{Bi}$ ,  $\text{Cd}$ ,  $\text{Cr}$ ,  $\text{Li}$ ,  $\text{Ni}$ ,  $\text{Pt}$ ,  $\text{Sr}$ ,  $\text{Y}$ ,  $\text{Zn}$ , and  $\text{Zr}$ , probably exist.

**Arsenic acid and Arsenates v. ARSENIC ACIDS OR.**

**Arsenides.** Binary compounds of arsenic with more positive elements, v. ARSENIC, *Combinations*, No. 9.

**Arsenious acids and Arsenites, v. ARSENIC ACIDS OR.**

M. M. P. M.

**ARSENIC COMPOUNDS, ORGANIC.** This article is devoted to compounds in whose molecules arsenic is supposed to be directly united to carbon. They are produced by distilling alkyl iodides with an alloy of arsenic with potassium or sodium (thus  $\text{MeI}$  gives  $\text{AsMe}_3$ ,  $\text{AsMe}_2\text{I}$ , and  $\text{AsMeI}_2$ —Cahours a. Riche, *C. R.* 39, 511), or by heating  $\text{AsCl}_3$  with compounds of mercury with alkyls or aromatic radicles or by the action of sodium on a mixture of  $\text{AsCl}_3$  and a haloid derivative. The methyl derivatives will be described first, followed by the methyl-ethyl, ethyl, phenyl, and finally by the benzyl, derivatives. The nomenclature employed is somewhat different from that used for derivatives of nitrogen. Thus the radicles  $\text{AsMe}$ ,  $\text{AsMe}_2$ ,  $\text{AsMe}_3$ , and  $\text{AsMe}_4$  are called methyl-arsine, dimethyl-arsine, tri-methyl-arsine, and tetramethyl-arsonium respectively.

**Methyl-arsine dichloride**  $\text{AsMe}_2\text{Cl}_2$ . (133°). At 40°–50° di-methyl arsine trichloride produces  $\text{AsMe}_2\text{Cl}_2$ , thus:  $\text{AsMe}_3\text{Cl}_3 = \text{MeCl} + \text{AsMe}_2\text{Cl}_2$ . Liquid which does not fume. M. sol. water but not decomposed by it. It violently attacks the mucous membrane. At –10° absorbs  $\text{Cl}_2$  forming  $\text{AsMe}_2\text{Cl}_4$  which at 0° splits up into  $\text{MeCl}$  and  $\text{AsCl}_3$  (Baeyer, *A.* 107, 257).

**Methyl-arsine di-iodide**  $\text{AsMeI}_2$ . [c. 25°]. From the oxide,  $\text{AsMeO}$ , and  $\text{HI}$ . From cacodyl and iodine (Cahours, *C. R.* 50, 1022). Yellow needles (from alcohol). Converted by  $\text{H}_2\text{S}$  into  $\text{AsMeS}$ , and by  $\text{HCl}$  into  $\text{AsMeCl}_2$ .

**Methyl-arsine sulphide**  $\text{AsMeS}$ . [110°]. From  $\text{H}_2\text{S}$  and  $\text{AsMe}_2\text{Cl}_2$ . Plates (from alcohol). Insol. water. Pps.  $\text{Ag}$ ,  $\text{Cu}$ , and  $\text{Pb}$ , as sulphides from their salts.

**Methyl-arsine disulphide**  $\text{AsMeS}_2$ . Formed by passing  $\text{H}_2\text{S}$  into an acidified solution of methane-arsonic acid (*G. Meyer*, *B.* 16, 1440).

**Methyl-arsine oxide**  $\text{AsMeO}$ . [95°]. Formed by action of  $\text{K}_2\text{CO}_3$  on the chloride  $\text{AsMeCl}_2$ . Crystallises from  $\text{CS}_2$  in irregular cubes, smells like *Asa fetida*. M. sol. cold, v. sol. hot, water; slightly volatile in vapour of water and alcohol; v. sol. aqueous acids forming neutral solutions.

**Methane arsonic acid**  $\text{MeAsO}(\text{OH})_2$ . From  $\text{AsMeCl}_2$  and excess of moist  $\text{Ag}_2\text{O}$ . From  $\text{AsMeO}$  in aqueous solution by action of  $\text{H}_2\text{O}$ . From aqueous sodium arsenite and  $\text{MeI}$  (M.). Large spear-shaped laminae composed of small needles (from alcohol).

**Salts.**— $\text{BaA}''$ ,  $5\text{H}_2\text{O}$ : ppd. as anhydrous rhombic crystals, by adding alcohol to aqueous solution; the crystals soon change to hydrated needles.  $\text{AgA}''$ : nacrous crystals which explode above 100°.— $\text{CaA}''$  aq.

**Tetra-methyl di-arsenide**  $\text{As}_2\text{Me}_4$ , *Cacodyl*, *Alkarsin*. Mol. w. 210. [c.  $-6^\circ$ ]. (c.  $170^\circ$ ). V.D. 7.1 (air = 1).

**Preparation.**—By heating di-methyl-arsine chloride (cacodyl chloride) with zinc at  $100^\circ$  in bulbs filled with  $\text{CO}_2$  (Bunsen, P. 40, 219; 42, 145; A. 87, 1; 42, 14; 46, 1).

**Properties.**—Stinking oil; heavier than water. Takes fire in air or in chlorine. Reduces  $\text{HgCl}_2$  to mercurous chloride.

**Reaction.**— $\text{As}_2\text{Me}_4 + 2\text{MeI} = \text{AsMe}_2\text{I} + \text{AsMe}_2\text{I}$  (Cahours, A. 122, 209).

**Combinations.**—When gradually mixed with air, chlorine, or bromine, it forms derivatives of cacodyl, behaving like a molecule of such a metal as potassium:  $(\text{AsMe}_2)_2 + \text{Cl}_2 = 2(\text{AsMe}_2)\text{Cl}$ ; and  $(\text{AsMe}_2)_2 + \text{O} = (\text{AsMe}_2)_2\text{O}$ .

**Tetra-methyl-di-arsine oxide**  $(\text{AsMe}_2)_2\text{O}$ , *Cacodyl oxide*. Mol. w. 226. [c.  $-25^\circ$ ]. ( $120^\circ$ ). S.G.  $1\frac{1}{2}$  1.462. V.D. 7.55 (calc. 7.83).

**Formation.**—Cadelet's fluid (*Recl. N. Chem. Arch.* 1, 212), obtained by distilling KOAc with an equal weight of  $\text{As}_2\text{O}_3$ , is cacodyl oxide mixed with some cacodyl.  $\text{HgO}$  converts both into cacodylic acid, whence a mixture of  $\text{HgCl}_2$  and fuming  $\text{HCl}$  forms cacodyl chloride. The latter is converted into cacodyl oxide by distilling with aqueous potash in a current of  $\text{CO}_2$  (Baeyer, A. 107, 282):  $2\text{AsMe}_2\text{Cl} + 2\text{KHO} = \text{H}_2\text{O} + 2\text{KCl} + (\text{AsMe}_2)_2\text{O}$ .

**Properties.**—Pungent, stinking oil. Slowly oxidises in air forming cacodylic acid. Acids convert it into salts of cacodyl.

**Compounds.**—Forms with  $\text{HgCl}_2$  a compound  $(\text{AsMe}_2)_2\text{O} \cdot 2\text{HgCl}_2$ , crystallising in trimetric plates. S. 3.47 at  $100^\circ$ . Distilled with fuming  $\text{HCl}$  this forms cacodyl chloride.  $(\text{AsMe}_2)_2\text{O} \cdot 2\text{HgBr}_2 \rightarrow (\text{AsMe}_2)_2\text{O} \cdot 3\text{AgNO}_3$ ; explodes at  $100^\circ$ .  $(\text{AsMe}_2)_2\text{O} \cdot \text{PtCl}_4$  aq.: red-brown pp. converted by  $\text{KBr}$  into  $(\text{AsMe}_2)_2\text{O} \cdot \text{PtBr}_4$  aq. and by  $\text{KI}$  into  $(\text{AsMe}_2)_2\text{O} \cdot \text{PtI}_4$ .

**Di-methyl-arsine chloride**  $\text{AsMe}_2\text{Cl}$ . (c.  $100^\circ$ ). V.D. 4.56 (calc. 4.85). Obtained from cacodylic acid as above; or by action of chlorine-water on cacodyl.—Heavy oil; attacks the mucous membrane; combines with  $\text{Cl}_2$  forming  $\text{AsMe}_2\text{Cl}_3$ . Zn, Sn, and Fe liberate  $\text{AsMe}_2$ .

**Compounds.**— $\text{AsMe}_2\text{Cl} \cdot \text{CuCl}$  (Bunsen).— $(\text{AsMe}_2\text{Cl})_2 \cdot \text{PtCl}_4$ .

**Di-methyl-arsine bromide**  $\text{AsMe}_2\text{Br}$ : yellow oil.

**Di-methyl-arsine iodide**  $\text{AsMe}_2\text{I}$  ( $160^\circ$ ): oil (Cahours a. Riche, A. 92, 364).

**Di-methyl-arsine cyanide**  $\text{AsMe}_2\text{Cy}$ . [ $33^\circ$ ]. ( $140^\circ$ ). V.D. 4.43. Prisms. Excessively poisonous.

**Di-methyl-arsine sulphide**  $(\text{AsMe}_2)_2\text{S}$ . Combines with S to form  $(\text{AsMe}_2)_2\text{S}_2$  ( $50^\circ$ ).

**Di-methyl-arsine fluoride**  $\text{AsMe}_2\text{F}$ . Liquid.

**Di-methyl-arsine trichloride**  $\text{AsMe}_2\text{Cl}_3$ .

**Cacodyl trichloride.** From  $\text{PCl}_5$  and cacodylic acid; or from cacodyl chloride and  $\text{Cl}_2$ .

**Reactions.**—1. At  $50^\circ$  it splits up as follows:  $\text{AsMe}_2\text{Cl} = \text{MeCl} + \text{AsMeCl}_2$ .—2. With water it forms cacodylic acid.

**Di-methyl-arsinic acid**  $\text{AsMe}_2\text{O}(\text{OH})$ , *Cacodylic acid*. Mol. w. 138. [ $200^\circ$ ].

**Formation.**—From cacodyl and  $\text{HgO}$  in presence of water.

**Properties.**—Large prisms (from alcohol), without odour, but poisonous. V. sol. water, m. sol. alcohol, insol. ether. Not acted on by  $\text{HNO}_3$ ,  $\text{HCl}$ , aqua regia,  $\text{KMnO}_4$ , or  $\text{CrO}_3$ .

**Reactions.**—1.  $\text{H}_2\text{PO}_4$  reduces it to cacodyl oxide.—2. Aqueous  $\text{H}_2\text{S}$  forms cacodyl sulphide.—3. An alcoholic solution gives with alcoholic  $\text{HgCl}_2$  a pp. of  $(\text{AsMe}_2)_2\text{O} \cdot \text{Hg}_2\text{Cl}_2$ .—4. Cacodylates are converted by dry  $\text{H}_2\text{S}$  into thio-cacodylates; e.g.  $(\text{AsMe}_2\text{S})_2\text{Pb}$ .— $\text{AsMe}_2\text{S}_2\text{Cu}$ .— $(\text{AsMe}_2\text{S})_2\text{Sb}$ .— $(\text{AsMe}_2\text{S})_2\text{Bi}$ .— $\text{AsMe}_2\text{S}_2\text{Au}$ .

**Salts.**—Soluble in water, but amorphous.  $\text{AgA'}$ : needles.— $\text{AgH}_2\text{A'}$ : needles.— $\text{AgA'AgNO}_3$ .

**Compounds.**— $\text{HCl}$  forms a crystalline compound  $(\text{AsMe}_2\text{O} \cdot \text{H} \cdot \text{HCl})$  decomposed by water. This compound distilled in a current of  $\text{HCl}$  splits up thus:  $\text{AsMe}_2\text{O} \cdot \text{H} \cdot \text{HCl} + 2\text{HCl} = \text{AsMe}_2\text{Cl}_2 + \text{MeCl} + 2\text{H}_2\text{O}$ .— $\text{H}_2\text{A'HF}$ : prisms.

**Tri-methyl arsine**  $\text{AsMe}_3$ . Mol. w. 120. (c.  $100^\circ$ ). **Formation.**—1.  $2\text{AsCl}_3 + 3\text{ZnMe}_2 = 3\text{ZnCl}_2 + 2\text{AsMe}_3$  (Hofmann).—2. From  $\text{AsMe}_2\text{I}$  and solid potash (Cahours, C. R. 49, 87).

**Properties.**—1. Combines directly with  $\text{Cl}_2$ ,  $\text{Br}_2$ ,  $\text{I}_2$ , S, and O.

**Iodide**  $\text{AsMe}_2\text{I}$ . Splits up on distillation into  $\text{MeI}$  and  $\text{AsMe}_2\text{I}$ , cacodyl iodide.—**Oxide**.  $\text{AsMe}_2\text{O}$ : deliquescent crystals.—**Sulphide**  $\text{AsMe}_2\text{S}$ : prisms (from alcohol).—**Bromide**  $\text{AsMe}_2\text{Br}$ .

**Tetra-methyl-arsonium iodide**  $\text{AsMe}_4\text{I}$ .

**Formation.**—1. From sodium arsenide and  $\text{MeI}$  at  $180^\circ$ , and treating the product  $(\text{AsMe}_4\text{IAsI}_2)$  with  $\text{KOH}$  (Cahours, C. R. 36, 1001; A. 122, 192).

**Properties.**—Plates (from alcohol mixed with  $\text{MeI}$ ).

**Combinations.**— $\text{AsMe}_4\text{I}_2$ .— $(\text{AsMe}_4\text{I})_2\text{ZnI}_2$ .— $(\text{AsMe}_4\text{I})_2\text{CdI}_2$ .— $\text{AsMe}_4\text{IAsI}_2$ .

**Reactions.**—1. With  $\text{ZnMe}_2$  gives  $\text{AsMe}_3$  (?) (Cahours).—2.  $\text{KOH}$  no action.—3. Moist  $\text{Ag}_2\text{O}$  gives  $\text{AsMe}_2\text{OH}$ , deliquescent alkaline crystals.—4.  $\text{Ag}_2\text{SO}_4$  gives crystalline  $(\text{AsMe}_2)_2\text{SO}_4$ .—5.  $\text{AgNO}_3$  forms crystalline  $\text{AsMe}_2\text{NO}_3$ .

**Penta-methyl-arsenide**  $\text{AsMe}_5$ . From  $\text{AsMe}_2\text{I}$  and  $\text{ZnMe}_2$ . With iodine forms  $\text{MeI}$  and  $\text{AsMe}_2\text{I}$ ; with  $\text{HCl}$  forms  $\text{CH}_3$  and  $\text{AsMe}_2\text{Cl}$  (Cahours).

**Di-methyl-ethyl-arsine.**— $\text{AsMe}_2\text{Et}$ . From  $\text{AsMe}_2\text{I}$  and  $\text{ZnEt}_2$ . Liquid (Cahours).

**Methyl-di-ethyl-arsine**  $\text{AsMeEt}_2$ . From  $\text{AsMeI}$  and  $\text{ZnEt}_2$  (Cahours).

**Di-methyl-di-ethyl arsonium salts.**

**Iodide.**— $\text{AsMe}_2\text{Et}_2\text{I}$ . From cacodyl and  $\text{EtI}$ , thus:  $\text{AsMe}_2 + 2\text{EtI} = \text{AsMe}_2\text{Et}_2\text{I} + \text{AsMe}_2\text{Cl}$  (Cahours a. Riche, C. R. 39, 541).

**Hydrazide:** very deliquescent.

**Chloride**  $\text{AsMe}_2\text{Et}_2\text{Cl}$ : deliquescent needles.

**Platino-chloride**  $(\text{AsMe}_2\text{Et}_2\text{Cl})_2 \cdot \text{PtCl}_4$ .

**Bromide**  $\text{AsMe}_2\text{Et}_2\text{Br}$ : deliquescent.

**Iodide**  $\text{AsMe}_2\text{Et}_2\text{I}$ : prisms.

**Periodide**  $\text{AsMe}_2\text{Et}_2\text{I}_2$ : lustrous prisms.

**Nitrate**  $\text{AsMe}_2\text{Et}_2\text{NO}_3$ : deliquescent grains.

**Sulphate**  $(\text{AsMe}_2\text{Et}_2)_2\text{SO}_4$ : octahedra.

**Ethyl-arsine iodide**  $\text{AsEtI}_2$ . From  $\text{AsEtI}$  and  $\text{I}_2$  (Cahours, C. R. 50, 1022; A. 116, 367). With moist  $\text{Ag}_2\text{O}$  it forms the acid  $\text{AsEtO}(\text{OH})_2$ .

**Ethyl-arsine chloride**  $\text{AsEtCl}_2$ . ( $156^\circ$ ). From  $\text{HgEt}_2$  and  $\text{AsCl}_3$  (La Coste, A. 208, 33). Liquid, m. sol. water.

**Ethane arsonic acid**  $\text{EtAsO}(\text{OH})_2$ . From the preceding by the action of diluted  $\text{HNO}_3$ . Small crystals (from alcohol).— $\text{Ag}_2\text{A'}$ : pearly scales.

**Tetra-ethyl-di-arsenide**  $\text{As}_2\text{Et}_4$ . Mol. w. 266. ( $185^\circ$ – $190^\circ$ ). From an alloy of arsenic and sodium on  $\text{EtI}$  (Landolt, A. 89, 319). Heavy stinking oil, takes fire in air. Reduces salts of silver and mercury. Unites directly with sulphur and

halogens. Alcoholic  $\text{HgCl}_2$  gives a crystalline precipitate  $\text{AsEt}_2\text{Cl}_2\cdot 2\text{Hg}_2\text{O}(\text{O})$ .

**Iodide**  $\text{AsEt}_2\text{I}$  (c. 230°). Oil.

**Di-ethyl-arsinic acid**  $\text{AsEt}_2\text{O}(\text{OH})$ . [190°]. From  $\text{AsEt}_2\text{I}$  and  $\text{HgO}$  under water (Landolt, *A.* 92, 865). Large plates, soluble in water. Not attacked by  $\text{HNO}_3$  or aqua regia.

**Salts**.— $\text{BaA}'\text{HA}'$  2aq. Very sol. in water, difficultly sol. in alcohol.

**Tri-ethyl-arsine**  $\text{AsEt}_3$ . Mol. w. 162. (140°–170°). S.G. 1.151. V.D. 5.28 (calc. 5.62).

**Formation**.—1. From  $\text{AsCl}_3$  and  $\text{ZnEt}_2$  (Hofmann a. Cahours, *C. R.* 41, 831).—2. Together with  $\text{As}_2\text{Et}_4$  by the action of  $\text{EtI}$  on an alloy of arsenic and sodium.—3. By distilling  $\text{AsEt}_2\text{I}$  with solid potash (Landolt, *A.* 89, 322).

**Properties**.—Oil of disagreeable odour. Fumes strongly in air. Combines directly with non-metals. Does not reduce ammoniacal silver nitrate (difference from  $\text{As}_2\text{Et}_4$ ).

**Combinations**.— $\text{AsEt}_2\text{Br}_2$ : deliquescent. —  $\text{AsEt}_2\text{I}_2$ . [160°]. (190°). (Cahours a. Riche, *A.* 92, 865).— $\text{AsEt}_2\text{S}$ . [c. 100°]. Prisms (from ether); pps. sulphides from solutions of metallic salts. —  $(\text{AsEt}_2)_2\text{PtCl}_2$ . —  $(\text{AsEt}_2)_2\text{PtCl}_4$ . —  $(\text{AsEt}_2)_2\text{PdCl}_2$  (Cahours a. Gal, *C. R.* 71, 208). —  $(\text{AsEt}_2\text{OAsEt}_2\text{Cl})_2\text{Hg}_2\text{Cl}_2$  (?). —  $\text{AsEt}_2\text{AuCl}$ . —  $\text{AsEt}_2\text{PtEt}_2(\text{C}_6\text{H}_5)_2\text{Br}_2\text{Br}$ .

**Tri-ethyl-arsine oxide**  $\text{AsEt}_2\text{O}$ . Formed by exposure of an ethereal solution of  $\text{AsEt}_2\text{I}$  to the air. An oil, insoluble in acids, except  $\text{HNO}_3$ .

**Tetra-ethyl-arsonium iodide**  $\text{AsEt}_4\text{I}$ .

**Formation**.—1. From  $\text{AsEt}_3$  and  $\text{EI}$  (Landolt, *A.* 89, 331).—2. Arsenic with  $\text{EtI}$  at 180° gives red needles of  $\text{AsEt}_4\text{IAsI}_2$ , which is then boiled with potash (Cahours a. Riche, *C. R.* 39, 516).—3. An alloy of arsenic with  $\text{Zn}$  or  $\text{Cd}$  heated with  $\text{EtI}$  gives  $(\text{AsEt}_2\text{I})_2\text{ZnI}_2$  or  $(\text{AsEt}_2\text{I})_2\text{CdI}_2$ ; these are boiled with potash (Cahours, *A.* 122, 200).

**Properties**.—Needles, v. sol. water and alcohol, insol. ether.

**Reactions**.—1. With moist  $\text{Ag}_2\text{O}$ , gives an alkaline hydrate.—2. Combines with  $\text{I}_2$  forming brown needles of  $\text{AsEt}_4\text{I}_2$ .

**Tetra-ethyl arsonium salts** (Landolt, *A.* 92, 371).

**Chloride**  $\text{AsEt}_2\text{Cl}$  4aq: deliquescent crystals, insol. ether.— $(\text{AsEt}_2\text{Cl})_2(\text{BiCl}_3)_2$  (Jørgensen, *J. pr.* [2] 3, 346).

**Platino-chloride**  $(\text{AsEt}_2\text{Cl})_2\text{PtCl}_2$ : sl. sol. cold water.

**Bromide**  $\text{AsEt}_2\text{Br}$ : deliquescent mass.— $(\text{AsEt}_2\text{Br})_2(\text{BiCl}_3)_2$ .

**Sulphate**  $\text{AsEt}_2\text{SO}_4\text{H}$ : grains, v. sol. water and alcohol, sl. sol. ether.

**Bromo-tetra-ethyl-arsonium bromide**  $(\text{CH}_3\text{Br}\cdot\text{CH}_2)_2\text{AsEt}_2\text{Br}$ . From ethylene bromide and  $\text{AsEt}_3$  at 50° (Hofmann, *Pr.* 11, 62). Rhombic dodecahedra (from alcohol)\*. V. sol. water, sl. sol. alcohol. Aqueous  $\text{AgNO}_3$  pps. half its bromine as  $\text{AgBr}$ .

**Reactions**.—1. With moist  $\text{Ag}_2\text{O}$  it gives vinyl triethyl arsonium hydroxide,  $\text{C}_2\text{H}_5\text{AsEt}_2(\text{OH})$ .—2. With  $\text{AsEt}_3$  it gives  $\text{As}_2(\text{C}_2\text{H}_5)_4\text{Et}_2\text{Br}_2$ .—3. With ammonia at 100° it gives a compound  $\text{NAs}(\text{C}_2\text{H}_5)_4\text{Et}_2\text{H}_2\text{Br}_2$ . This compound and the preceding are converted by  $\text{Ag}_2\text{O}$  into oxides and thence into platinochlorides (e.g.  $\text{NAs}(\text{C}_2\text{H}_5)_4\text{Et}_2\text{H}_2\text{Cl}_2\text{PtCl}_2$ ) and other salts.—

4.  $\text{AuCl}_3$  gives crystals of  $\text{AsEt}_2\text{AuCl}$ .—5.  $\text{PtCl}_4$  gives crystals of  $\text{As}_2\text{Et}_2\text{Pt}$  (Hofmann, *A.* 103, 357).

**Di-methyl-di-isoamyl-arsonium iodide**

$\text{AsMe}_2(\text{C}_4\text{H}_9)_2\text{I}$ . From cacodyl and iso-amyl iodide at 180°, as follows:  $\text{AsMe}_2 + 2\text{C}_4\text{H}_9\text{I} = \text{AsMe}_2(\text{C}_4\text{H}_9)_2\text{I} + \text{AsMe}_2\text{I}$  (Cahours a. Riche).

**Tri-propyl-arsine**  $\text{AsPr}_3$ . At 180°, arsenic combines with  $\text{PrI}$  forming  $\text{AsPr}_3\text{IASI}_2$ . Distilled with solid potash, this gives  $\text{AsPr}_3$  (Cahours, *C. R.* 76, 1383). Arsenic acts similarly on isobutyl iodide at 180° (Cahours, *C. R.* 77, 1406). Calcium butyrate distilled with  $\text{As}_2\text{O}_3$  gives a distillate resembling Cadet's liquid, probably containing the propyl homologues of cacodyl compounds (Wöhler, *A.* 68, 127). Potassium valerate distilled with  $\text{As}_2\text{O}_3$  appears similarly to give 'butyl-cacodyl' derivatives (Gibbs, *Am. S.* [2] 15, 118).

AROMATIC DERIVATIVES.

**Literature**.—Michaelis, *A.* 201, 184; 207, 195; 208, 1; 233, 60; *B.* 8, 1316; 9, 1566; 10, 622; 11, 1883; 13, 2176; 14, 912; 15, 1952, 2876; 18, 42; *La Coste*, *A.* 184, 1; 208, 1.

**Di-phenyl-di-arsenide**  $\text{C}_6\text{H}_5\text{As}_2\text{C}_6\text{H}_5$ . **Arseno-benzene**. [196°]. Prepared by reduction (best with phosphorous acid) of an alcoholic solution of phenyl-arsine oxide (Michaelis a. Schulte, *B.* 11, 912; 15, 1952). Yellowish needles. Sol. benzene, chloroform, and  $\text{CS}_2$ ; sl. sol. alcohol, insol. water and ether. On heating it gives triphenyl-arsine and arsenic.

**Reactions**.—1. Heated with 1 mol. of sulphur phenyl-arsine sulphide is formed, with more sulphur, phenyl sulphide and  $\text{As}_2\text{S}_3$ .—2. Alcoholic  $\text{NH}_4\text{HS}$  reduces it on heating to benzene,  $\text{As}_2\text{S}_3$ , and  $\text{As}$ ;  $\text{HI}$  acts in a similar manner.—3. On oxidation it gives benzene-arsonic acid.—4. Combines directly with halogens.

**Di-iodide**.— $\text{PhAsIAsI}\cdot\text{Ph}$ . Yellow needles. Very unstable. Prepared by reduction of phenyl-arsine iodide (which is formed by dissolving phenyl-arsine oxide in  $\text{HI}$ ).

**Phenyl-arsine chloride**  $\text{PhAsCl}_2$  (c. 253°). Obtained in theoretical quantity by heating  $\text{AsCl}_3$  (800g.) with  $\text{HgPh}_2$  (70g.). Colourless liquid with unpleasant odour; insol. water, sol.  $\text{KOH}$  aq.

**Phenyl-arsine tetra-chloride**  $\text{PhAsCl}_4$  [45°]. Formed by passing  $\text{Cl}$  into the preceding at 0°. Yellow needles, fuming in moist air; readily decomposed into  $\text{Cl}_2$  and  $\text{PhAsCl}_2$ ; when heated at 150° it gives  $\text{C}_6\text{H}_5\text{Cl}$  and  $\text{AsCl}_3$ .

**Phenyl-arsine bromide**  $\text{PhAsBr}_2$ . (285°). S.G. 2.10. Colourless liquid formed by the action of conc.  $\text{HBr}$  upon  $\text{PhAsO}$ . Gives with bromine  $\text{AsBr}_3$  and  $\text{PhBr}$ .

**Phenyl-arsine iodide**  $\text{PhAsI}_2$ . Oil.

**Phenyl-arsine oxide**  $\text{PhAsO}$ . [120°]. Formed by treating  $\text{PhAsCl}_2$  with  $\text{Na}_2\text{CO}_3$ . Crystals (from alcohol); smells like anise; insol. water; sl. sol. cold, m. sol. hot, alcohol; slightly volatile with steam. Heated with  $\text{HCl}$  it forms  $\text{PhAsCl}_2$ . Above its melting-point it decomposes thus:

**Phenyl-arsine oxy-chloride**  $\text{PhAsOCl}_2$  [100°]. Formed by decomposing the tetrachloride with the theoretical quantity of water; or by the union of chlorine with the oxide. Crystalline; dissolved by water, being converted into benzene-arsonic acid. At 120° it splits up thus:

**Sensene-arsenic acid**  $C_6H_4AsO(OH)_2$ .

Formed by dissolving  $PhAsCl_2$  or  $PhAsOCl_2$  in water. Long columns; begins to soften at  $138^\circ$ , changing to an amorphous anhydride, which is re-converted by water into the acid. M. sol. cold, v. sol. hot, water.

Reactions.—1. Not affected by reducing or oxidising agents.—2. Potash fusion produces phenol.

Salts.— $NH_4A'$ : needles.— $KHA'$ : amorphous.— $BaH_2A'_2$ : needles, v. sol. water.— $CaH_2A'_2$ : needles.— $CaA'^{2+}$ — $CuA'$ : v. sl. sol. water.— $PhA'$ : insol. water.

**Tetra-phenyl-di-arsenide**  $As_2(C_6H_5)_4$ , *Phenylcacodyl*. [ $135^\circ$ ]. Formed by reduction of tetra-phenyl-di-arsine oxide with phosphorous acid. White crystals. Sl. sol. alcohol and ether. It quickly oxidises in the air, forming di-phenyl-arsinic anhydride  $(Ph_2As)_2O$ .

**Di-phenyl-arsine chloride**  $Ph_2AsCl$ , *Phenylcacodyl chloride*. [ $333^\circ$ ]. S.G. 1.142. Prepared by heating  $HgPh_2$  with a large excess of  $PhAsCl_2$  at  $320^\circ$ . The product is then fractionally distilled. Yellow oil, insol. water, sol. alcohol, ether, and benzene, sl. sol. aqueous alkalis. Not affected by heating with  $Na_2CO_3$ . Combines with bromine and chlorine. Conc.  $HNO_3$  slowly converts it into di-phenyl-arsinic acid.

**Di-phenyl-arsine trichloride**  $Ph_2AsCl_3$ , [ $174^\circ$ ]. From the preceding and chlorine. Colourless tables (from benzene). At  $200^\circ$  it decomposes thus:  $Ph_2AsCl_3 = PhAsCl_2 + PhCl$ .

**Di-phenyl-arsine chloro-bromide**  $Ph_2AsClBr$ . Formed by passing dry bromine-vapour into  $Ph_2AsCl$ . Excess of Br produces di-bromo-benzene.

**Tetra-phenyl-di-arsine oxide**  $(Ph_2As)_2O$ , [ $92^\circ$ ]. Formed by heating  $Ph_2AsCl$  with alcoholic KOH.

**Di-phenyl-arsine bromide**  $Ph_2AsBr$ . [ $356^\circ$ ]. From the oxide and HBr.

**Di-phenyl-arsine oxy-chloride**  $(Ph_2AsCl_2)_2O$ , [ $117^\circ$ ]. From the oxide and chlorine.

**Di-phenyl-arsinic acid**  $Ph_2AsO.OH$ , [ $174^\circ$ ]. S.G. 1.55. From the oxy-chloride or the trichloride by the action of water. White needles; sol. water and alcohol, sl. sol. benzene and ether. Not attacked by  $CrO_3$  or boiling conc.  $HNO_3$ .

Salts.— $NaA'$ — $NH_4A'$ : unstable feathery crystals.— $BaA'_2$ — $CuA'_2$ — $HIO.CuA'$ — $AgA'$ — $PbA'_2$ .

**Tri-phenyl-arsine**  $AsPh_3$ , [ $59^\circ$ ]. (above  $360^\circ$ ). S.G. 1.306. Prepared by heating phenyl-arsine oxide at  $200^\circ$ , thus:  $3PhAsO = AsPh_3 + As_2O_3$ . More readily by the action of sodium (50 g.) on  $AsCl_3$  (54 g.) and chloro-benzene (101 g.), diluted with 4 vols. dry ether. Is also a by-product in preparing  $Ph_2AsCl$  from  $PhAsCl_2$  and  $HgPh_2$ . Triclinic crystals isomorphous with  $SbPh_3$  (Phillips, B. 19, 1031). Insol. water and dilute acids, v. sol. hot alcohol, benzene, and ether. With  $HgCl_2$  it forms leaflets of  $AsPh_3.HgCl_2$ , whence aqueous KOH forms  $AsPh_3(OH)_2$ , [ $108^\circ$ ], thus:  $AsPh_3.HgCl_2 + 2KOH = AsPh_3(OH)_2 + 2KCl + Hg$ .

**Tri-phenyl-arsine chloride**  $Ph_3AsCl_2$ , [ $171^\circ$ ]. From  $AsPh_3$  and chlorine. Tables; decomposed at  $280^\circ$  into  $Ph_2AsCl$  and  $PhCl$ .

**Tri-phenyl-arsine sulphide**  $Ph_3AsS$ , [ $162^\circ$ ]. Prepared by digesting  $Ph_3As$  with S dissolved in  $CS_2$ ; or by action of ammonium sulphide on  $Ph_3AsCl_2$ . Silky needles, insol. water and ether.

**Tri-phenyl-arsine oxy-nitrate**

$(C_6H_5)_3As(OH)NO_2$ , [ $84^\circ$ ]. Formed by adding  $HNO_3$  to an aqueous solution of the hydroxide  $(C_6H_5)_3As(OH)_2$  (Phillips, B. 19, 1033). Long glistening needles. V. sol. alcohol, sl. sol. water.

**Tri-nitro-tri-phenyl-arsine oxide**

$(C_6H_5)_3NO_2AsO$ , [ $254^\circ$ ]. Formed by nitration of tri-phenyl-arsine-hydrate,  $(C_6H_5)_3As(OH)_2$ , with  $HNO_3$  and  $H_2SO_4$ . Nearly colourless large crystals. V. sol. acetic acid, insol. alcohol and ether.

**Tri-amido-tri-phenyl-arsine**  $(C_6H_5)_3As$ , [c.  $176^\circ$ ]. Formed by reduction of tri-nitro-tri-phenyl-arsine oxide  $(C_6H_5)_3NO_2AsO$  with tin and HCl in acetic acid solution (P.). Colourless crystalline solid. V. sol. alcohol and dilute acids, insol. water.

Salts.— $B'''H_2Cl_2$ : crystalline solid, easily soluble in water and alcohol.— $(B'''H_2Cl_2)_2(PtCl_4)_2$ : yellow pp., insol. cold water.

**Tri-acetyl-derivative**  $(C_6H_5)_3NHAc$ ,  $As$ , [c.  $230^\circ$ ]. Very sparingly soluble in alcohol, more easily in acetic acid.

**Tri-p-methoxy-tri-phenyl-arsine**

$(EtO.C_6H_4)_3As$ , *Tri-phenetyl-arsine*, [ $89^\circ$ ]. Formed by the action of sodium upon a mixture of *p*-bromo-phenetol and  $AsCl_3$  (Michaelis a. Weitz, B. 20, 52).

**tri-p-methoxy-tri-phenyl arsine**

$(MeO.C_6H_4)_3As$ , *Tri-anisyl-arsine*, [ $156^\circ$ ]. Obtained by the action of sodium upon a mixture of *p*-bromo-anisol and  $AsCl_3$  containing some acetic ether. Transparent colourless crystals. V. sol. benzene, sl. sol. alcohol and ether. HI splits it up into di-anisyl-arsine iodide  $(C_6H_4(OMe)_2)_2AsI$  and anisol; by longer and higher heating anisol and  $AsI_3$  are formed. By heating with an excess of  $AsCl_3$  it yields anisyl-arsine chloride  $C_6H_4(OMe)_2AsCl_2$  (Michaelis a. Weitz, B. 20, 48).

**Di-p-methoxy-di-phenyl-arsine chloride**

$(C_6H_4(OMe)_2)_2AsCl$  [1:4]. *Di-anisyl-arsine chloride*, [ $80^\circ$ ]. Formed by dissolving the oxide in HCl. Long thin needles. V. sol. ether, less in alcohol.

**Di-methoxy-di-phenyl-arsine oxide**

$\{C_6H_4(OMe)_2\}_2As_2O$  [1:4]. *Di-anisyl-arsine oxide*, *Tetra-anisyl-di-arsine oxide*, [ $130^\circ$ ]. Crystalline. Formed by the action of alkalis on the iodide which is obtained by heating tri-anisyl-arsine with HI.

**p-Methoxy-benzene-arsine chloride**

$C_6H_4(OMe)_2AsCl_2$  [1:4]. *p-Anisyl-arsine chloride*, ( $230^\circ$  at 117 mm.). Colourless liquid. Formed by heating tri-anisyl-arsine  $(C_6H_4(OMe)_2)_3As$  with an excess of  $AsCl_3$  at  $200^\circ$ . Alkalis yield the oxide  $C_6H_4(OMe)_2AsO$ , a colourless crystalline solid. It combines with  $Cl_2$  to form  $C_6H_4(OMe)_2AsCl_2$ , which is a thick yellow liquid decomposed by water giving anisyl-arsinic acid  $C_6H_4(OMe)_2AsO(OH)_2$ .

**p-Methoxy-benzene-arsenic acid**

$(C_6H_4(OMe)_2)_2AsO(OH)_2$ , *Anisyl-arsinic acid*, [ $160^\circ$ ]. Formed by the action of water upon the chloride  $C_6H_4(OMe)_2AsCl_2$ . Colourless crystalline solid. Sol. hot, sl. sol. cold, water; v. sol. alcohol. On heating it gives the anhydride  $C_6H_4(OMe)_2AsO_2$ — $Ag_2A'$ : white pp.

**Phenyl-di-methyl-arsine**  $PhAsMe_2$ , ( $200^\circ$ ). From  $ZnMe_2$  and  $PhAsCl_2$ . Mobile liquid, sol. alcohol and benzene, insol. water.

**Phenyl-tri-methyl-arsonium iodide**

$PhAsMe_3I$ , [ $244^\circ$ ]. From the preceding and

MeI. White needles; sol. water and alcohol, insol. ether.—(PhAsMe<sub>2</sub>Cl)<sub>2</sub>PtCl<sub>4</sub> [219°]; v. sol. hot water.

**Di-phenyl-methyl-arsine** Ph<sub>2</sub>AsMe. (306°). From Ph<sub>2</sub>AsCl and ZnMe<sub>2</sub> in benzene (Michaelis a. Link, A. 207, 199). Insol. water.

**Di-phenyl-di-methyl-arsonium iodide** Ph<sub>2</sub>AsMe<sub>2</sub>I. [190°]. From the preceding and MeI. Needles; sl. sol. cold, v. sol. hot, water. Decomposed by heat into MeI and Ph<sub>2</sub>AsMe.—(Ph<sub>2</sub>AsMe<sub>2</sub>Cl)<sub>2</sub>PtCl<sub>4</sub> [219°].

**Phenyl-di-ethyl-arsine** PhAsEt<sub>2</sub>. (240°). From PhAsCl<sub>2</sub> and ZnEt<sub>2</sub>. Colourless liquid. Combines with Cl<sub>2</sub> forming PhAsEt<sub>2</sub>Cl<sub>2</sub>.

**Phenyl-tri-ethyl-arsonium iodide** PhAsEt<sub>3</sub>I. [113°]. From the preceding and EtI at 100°. Prisms, turned yellow by sunlight; sol. water and alcohol, insol. ether. Decomposed when heated in an indifferent gas into EtI and PhAsEt<sub>2</sub>. Gives with AgCl the chloride PhAsEt<sub>2</sub>Cl; whence (PhAsEt<sub>2</sub>Cl)<sub>2</sub>PtCl<sub>4</sub>. Gives with Ag<sub>2</sub>O the hydroxide PhAsEt<sub>2</sub>OH, an alkaline syrup, absorbing CO<sub>2</sub> from the air.

**Di-phenyl-ethyl-arsine** Ph<sub>2</sub>AsEt. (320°). From Ph<sub>2</sub>AsCl and ZnEt<sub>2</sub>. Colourless liquid.

**Di-phenyl-ethyl-arsine chloride** Ph<sub>2</sub>AsEtCl<sub>2</sub>. [137°]. From the preceding and Cl<sub>2</sub>. Needles (from benzene); fumes in the air; decomposed by water.

**Di-phenyl-di-ethyl-arsonium iodide** Ph<sub>2</sub>AsEt<sub>2</sub>I. [181°]. From Ph<sub>2</sub>AsEt and EtI. Flat white needles.

**Di-phenyl-methyl-ethyl-arsonium iodide** Ph<sub>2</sub>AsMeEtI. [170°]. S. 1:1 at 15°; 8:1 at 100°. From Ph<sub>2</sub>AsMe and EtI or from Ph<sub>2</sub>AsEt and MeI. Trimetric prisms; insol. ether. Split up by heat into EtI and Ph<sub>2</sub>AsMe.

**Derivatives.**—(Ph<sub>2</sub>AsMeEt)<sub>2</sub>PtCl<sub>4</sub>. [214°]. **Picrate** Ph<sub>2</sub>AsMeEt.O.C<sub>6</sub>H<sub>4</sub>(NO<sub>2</sub>)<sub>3</sub>. [95°]. Sl. sol. cold water.

**Tolyl-arsine chloride** C<sub>6</sub>H<sub>4</sub>AsCl<sub>2</sub>. **Ortho** (265°). **Para** [31°]. (267°). From AsCl<sub>3</sub> and mercuric di-tolyl (o- or p-). Bromine converts them into di-bromo-toluenes. **Tolyl-arsine tetrachloride** C<sub>6</sub>H<sub>4</sub>AsCl<sub>4</sub>.

**Tolyl-arsine oxide** C<sub>6</sub>H<sub>4</sub>AsO. **Ortho** [145°]. **Para** [156°]. From C<sub>6</sub>H<sub>4</sub>AsCl<sub>2</sub> and aqueous Na<sub>2</sub>CO<sub>3</sub>. Combine with Cl<sub>2</sub> forming oxy-chlorides.

**Toluene arsonic acid** CH<sub>3</sub>C<sub>6</sub>H<sub>4</sub>AsO(OH)<sub>2</sub>. **Ortho** [160°]. The *para* compound decomposes above 300° without previous fusion.

From the tetrachloride or the oxychloride, C<sub>6</sub>H<sub>4</sub>AsOCl<sub>2</sub>, by treatment with water. The *ortho* acid forms a crystalline anhydride C<sub>6</sub>H<sub>4</sub>AsO<sub>2</sub>—Ag<sub>2</sub>A'—BaA'—CaA' (La Coste a. Michaelis, A. 201, 255).

**Di-p-tolyl-arsine .chloride** (C<sub>6</sub>H<sub>4</sub>)<sub>2</sub>AsCl. (c. 343°). From C<sub>6</sub>H<sub>4</sub>AsCl<sub>2</sub> and H<sub>2</sub>(C<sub>6</sub>H<sub>4</sub>)<sub>2</sub>. Liquid; not affected by aqueous Na<sub>2</sub>CO<sub>3</sub>. Chlorine gives (C<sub>6</sub>H<sub>4</sub>)<sub>2</sub>AsCl<sub>2</sub>.

**Tetra-p-tolyl-di-arsine oxide** ((C<sub>6</sub>H<sub>4</sub>)<sub>2</sub>As)<sub>2</sub>O. (98°). Silky needles (from ether). Obtained by boiling the preceding with alcoholic KOH.

**Di-p-tolyl-arsinic acid** (C<sub>6</sub>H<sub>4</sub>)<sub>2</sub>AsO.OH. [167°]. Formed by boiling (C<sub>6</sub>H<sub>4</sub>)<sub>2</sub>AsCl<sub>2</sub> with water. Oxidised to 'dibenzarsinic' acid.

**Tri-p-tolyl-arsine** (C<sub>6</sub>H<sub>4</sub>)<sub>3</sub>As. [145°]. Obtained by heating C<sub>6</sub>H<sub>4</sub>AsO.

**Tri-p-tolyl-arsine dichloride** (C<sub>6</sub>H<sub>4</sub>)<sub>3</sub>AsCl<sub>2</sub>. [214°]. Not attacked by water.

VOL. I.

**p-Carboxy-phenyl-arsine chloride** CO<sub>2</sub>H.C<sub>6</sub>H<sub>4</sub>AsCl<sub>2</sub>. [158°]. From the corresponding iodide and AgCl; or from the product (COCl.C<sub>6</sub>H<sub>4</sub>AsCl<sub>2</sub>) (?) of the action of PCl<sub>5</sub> upon CO<sub>2</sub>H.C<sub>6</sub>H<sub>4</sub>AsO(OH)<sub>2</sub> by treating with water. Needles (from benzene); decomposed by water.

**p-Carboxy-phenyl-arsine iodide** CO<sub>2</sub>H.C<sub>6</sub>H<sub>4</sub>AsI. [153°]. From CO<sub>2</sub>H.C<sub>6</sub>H<sub>4</sub>AsO(OH)<sub>2</sub> by HI and P. Yellow needles (from chloroform).

**p-Carboxy-phenyl-arsine hydroxide** CO<sub>2</sub>H.C<sub>6</sub>H<sub>4</sub>As(OH)<sub>2</sub>. *Benzarsenious acid*. From the preceding by heating with aqueous Na<sub>2</sub>CO<sub>3</sub>. Colourless needles (from water). At 145°–160° it gives off H<sub>2</sub>O leaving the oxide CO<sub>2</sub>H.C<sub>6</sub>H<sub>4</sub>AsO. — Ca(C<sub>6</sub>H<sub>4</sub>AsO<sub>2</sub>)<sub>2</sub>.Aq; plates; changing at 200° into Ca(C<sub>6</sub>H<sub>4</sub>AsO<sub>2</sub>)<sub>2</sub>—AgC<sub>6</sub>H<sub>4</sub>AsO<sub>2</sub>.

**p-Carboxy-benzene arsonic acid** CO<sub>2</sub>H.C<sub>6</sub>H<sub>4</sub>AsO(OH)<sub>2</sub>. *Benzarsenic acid*. Formed by oxidising toluene arsonic acid with alkaline KMnO<sub>4</sub>. Transparent interlaced needles; m. sol. water, v. sl. sol. alcohol. At 190° it becomes CO<sub>2</sub>H.C<sub>6</sub>H<sub>4</sub>AsO<sub>2</sub>; at 230° it gives off benzoic acid. — Ag<sub>2</sub>A'. — CaHA'' aq. — KH<sub>2</sub>A'' — MeHA''.

**p-Di-carboxy-di-phenyl-arsine iodide** (CO<sub>2</sub>H.C<sub>6</sub>H<sub>4</sub>)<sub>2</sub>AsI. [above 280°]. From (CO<sub>2</sub>H.C<sub>6</sub>H<sub>4</sub>)<sub>2</sub>AsO.OH, conc. HI, and P. Converted by aqueous Na<sub>2</sub>CO<sub>3</sub> into the hydroxide (CO<sub>2</sub>H.C<sub>6</sub>H<sub>4</sub>)<sub>2</sub>AsOH. (*Dibenzarsenious acid*). — CaA'' 2aq.

**p-Di-carboxy-di-phenyl-arsinic acid** (CO<sub>2</sub>H.C<sub>6</sub>H<sub>4</sub>)<sub>2</sub>AsO.OH. *Dibenzarsinic acid*. Formed from (C<sub>6</sub>H<sub>4</sub>)<sub>2</sub>AsO.OH and alkaline KMnO<sub>4</sub> at 60°. Leaflets, insol. water, sl. sol. alcohol. — Me<sub>2</sub>HA'' [above 280°].

**p-Tri-carboxy-tri-phenyl-arsine** (CO<sub>2</sub>H.C<sub>6</sub>H<sub>4</sub>)<sub>3</sub>As. *Tribenzarsenious acid*. From the following acid and HI. Small colourless needles. — Na<sub>2</sub>A'' 2aq. — Ag<sub>2</sub>A''.

**p-Tri-carboxy-tri-phenyl-arsine hydroxide** (CO<sub>2</sub>H.C<sub>6</sub>H<sub>4</sub>)<sub>3</sub>As(OH)<sub>2</sub>. *Tribenzarsinic acid*. From tri-tolyl-arsine and alkaline KMnO<sub>4</sub>. — (CO<sub>2</sub>K.C<sub>6</sub>H<sub>4</sub>)<sub>3</sub>AsO.

**Benzyl-arsine chloride** PhCH<sub>2</sub>AsCl<sub>2</sub>. (175°) at 50mm. Formed by heating tri-benzyl-arsine with excess of AsCl<sub>3</sub>. Easily oxidised by air: PhCH<sub>2</sub>AsCl<sub>2</sub> + O = PhCH<sub>2</sub>Cl + AsOCl.

**Di-benzyl-arsinic acid** (PhCH<sub>2</sub>)<sub>2</sub>AsO.OH [210°].

**Preparation.**—Sodium [50 g.] acting upon a solution of benzyl chloride (100 g.) and AsCl<sub>3</sub> (72 g.) in dry ether (500 g.) containing acetic ether (5 g.) forms (PhCH<sub>2</sub>)<sub>2</sub>As, (PhCH<sub>2</sub>)<sub>3</sub>AsCl<sub>2</sub>, and (PhCH<sub>2</sub>)<sub>3</sub>AsCl<sub>2</sub>. Alcohol extracts the first, and converts the two latter into (PhCH<sub>2</sub>)<sub>2</sub>AsCl(OH)<sub>2</sub> and (PhCH<sub>2</sub>)<sub>3</sub>AsCl(OH) respectively, and they are then converted by aqueous NaOH into (PhCH<sub>2</sub>)<sub>2</sub>AsO.ONa and (PhCH<sub>2</sub>)<sub>3</sub>AsO (Michaelis a. Pactoff, A. 233, 60).

**Properties.**—Pearly white plates (from alcohol); attacks the mucous membrane; v. sol. hot alcohol, m. sol. hot water, sl. sol. ether. When strongly heated it gives benzoic aldehyde and dibenzyl.

**Salts.**—BaA', 8aq.—CaA', 6aq.—AgA'.

**Reactions.**—1. Conc. HCl forms AsCl<sub>3</sub> toluene, and benzyl chloride.—2. Boiling dilute HNO<sub>3</sub> has no effect; HNO<sub>3</sub> of S.G. 1.8 forms a compound (PhCH<sub>2</sub>)<sub>2</sub>As(OH)<sub>2</sub>NO<sub>3</sub> [129°]; conc

Y

**ENO**, forms benzoic and arsenic acids.—8. **Compounds** with HCl forming  $(\text{PhCH}_2)_2\text{AsCl}(\text{OH})_2$  which crystallises from aqueous HCl in needles [128°]; this is decomposed by more water, giving  $(\text{PhCH}_2)_2\text{AsO}_2\text{OH}$  again.—4. **HBr** forms  $(\text{PhCH}_2)_2\text{AsO}(\text{OH})\text{HBr}$ .

**Di-benzyl-thio-arsinic acid**  $(\text{PhCH}_2)_2\text{AsO}_2\text{SH}$ . [199°]. From di-benzyl-arsinic acid and  $\text{H}_2\text{S}$  in alkaline solution.

**Tri-benzyl-arsine**  $(\text{PhCH}_2)_3\text{As}$ . [104°]. The preparation is described under di-benzyl-arsinic acid (*v. sup.*). Monoclinic needles (from alcohol). Insol. water; v. sol. ether, benzene, and glacial acetic acid; sl. sol. cold alcohol. Like  $\text{AsMe}_3$ , but unlike  $\text{AsPh}_3$ , it combines with alkyl iodides. It is not affected by boiling conc. HCl. It combines with S and halogens. Boiling dilute  $\text{HNO}_3$  forms benzoic and arsenic acids. An ethereal solution gives with an ethereal solution of  $\text{HgCl}_2$  a pp. of  $(\text{PhCH}_2)_3\text{AsHgCl}_2$  [159°].

**Tri-benzyl-arsine oxide**  $(\text{PhCH}_2)_3\text{AsO}$ . [220°]. From tri-benzyl-arsine chloride or oxychloride by treatment with alkalis; or together with di-benzyl-arsinic acid by the action of wet ether upon the product of the action of sodium upon benzyl chloride and  $\text{AsCl}_3$ . Prisms (from dilute alcohol); v. e. sol. alcohol, sl. sol. water and ether.

**Tri-benzyl-arsine oxy-chloride**  $(\text{PhCH}_2)_3\text{AsCl}(\text{OH})$ . [163°]. Formed by union of HCl with the preceding. V. o. sol. alcohol; insol. dilute HCl.

**Tri-benzyl-arsine oxy-bromide**  $(\text{PhCH}_2)_3\text{AsBr}(\text{OH})$ . [129°]. Tables (from alcohol).

**Tri-benzyl-arsine iodide**  $(\text{PhCH}_2)_3\text{AsI}$ . [c. 95°]. Formed in impure condition by action of aqueous  $\text{HI}$  on the oxide. Converted by alcohol into the oxy-iodide,  $(\text{PhCH}_2)_3\text{AsI}(\text{OH})$  aq [78°].

**Tri-benzyl-arsine-oxy-nitrate**  $(\text{PhCH}_2)_3\text{As}(\text{NO}_3)(\text{OH})$ . [170°]. Slender needles (from alcohol).

**Tri-benzyl-arsine sulphide**  $(\text{PhCH}_2)_3\text{AsS}$ . [214°]. Prisms (from glacial  $\text{HOAc}$ ). Insol. alcohol and ether.

**Tri-benzyl-methyl-arsonium iodide**  $(\text{PhCH}_2)_3\text{AsMeI}$ . [143°]. From  $(\text{PhCH}_2)_3\text{As}$  and  $\text{MeI}$  at 100°. Slender needles (from water). Gives with moist  $\text{Ag}_2\text{O}$  the alkaline hydroxide,  $(\text{PhCH}_2)_3\text{AsMe}(\text{OH})$ .

**Tri-benzyl-methyl-arsonium chloride**  $(\text{PhCH}_2)_3\text{AsMeCl}$ . [201°]. — *Platinochloride*  $(\text{PhCH}_2)_3\text{AsMe}(\text{O})_2\text{PtCl}_6$ . [173°].

**Tri-benzyl-ethyl-arsonium iodide**  $(\text{PhCH}_2)_3\text{AsEtI}$ . [148°]. White plates (from water).

**Tri-benzyl-propyl-arsonium iodide**  $(\text{PhCH}_2)_3\text{AsPrI}$ . [146°]. The isomeride,  $(\text{PhCH}_2)_3\text{AsPrI}$  melts at [143°].

**Tri-benzyl-isoamyl-arsonium iodide**  $(\text{PhCH}_2)_3\text{As}(\text{C}_4\text{H}_9)\text{I}$ . [146°].

**Tetra-benzyl-arsonium chloride**  $(\text{PhCH}_2)_4\text{AsCl}$ . [160°]. From  $(\text{PhCH}_2)_3\text{As}$  and  $\text{PhCH}_2\text{Cl}$  at 170°. Triclinic crystals containing aq (from water); insol. dilute HCl. Converted by aqueous  $\text{KBr}$  into the bromide  $(\text{PhCH}_2)_4\text{AsBr}$ . [173°], and by aqueous  $\text{KI}$  into the iodide,  $(\text{PhCH}_2)_4\text{AsI}$ . [168°], which forms a periodide,  $(\text{PhCH}_2)_4\text{AsI}_3$ . [150°]. Moist  $\text{Ag}_2\text{O}$  forms an alkaline hydroxide, split up by heat thus:  $(\text{PhCH}_2)_4\text{AsOH} = \text{PhCH}_2 + (\text{PhCH}_2)_2\text{AsO}$ .

*Platinochloride*  $((\text{PhCH}_2)_4\text{As})_2\text{PtCl}_6$ .

**Di-naphthyl di-arsenide**  $\text{C}_{10}\text{H}_7\text{As}_2\text{C}_{10}\text{H}_7$ . *Arseno-naphthalene*. [221°]. Prepared by heating an alcoholic solution of naphthyl-arsine oxide with phosphorous acid (Michaelis & Schulte, *B.* 15, 1954). Slender yellow needles; sl. sol. alcohol, benzene,  $\text{CS}_2$  and chloroform; insol. water and ether. Converted by  $\text{Cl}$  into  $\text{C}_{10}\text{H}_7\text{AsCl}_2$ . With sulphur it gives  $\text{C}_{10}\text{H}_7\text{AsS}$ . It is oxidised by  $\text{HNO}_3$  to naphthalene arsonic acid.

**Naphthyl-arsine chloride**  $\text{C}_{10}\text{H}_7\text{AsCl}_2$ . [68°]. From mercury di-naphthyl and  $\text{AsCl}_3$ . Crystalline powder; insol. water, v. sol. alcohol.

**Naphthyl-arsine oxide**  $\text{C}_{10}\text{H}_7\text{AsO}$ . [245°]. From the preceding by treatment with aqueous  $\text{Na}_2\text{CO}_3$ . Powder; sl. sol. alcohol, ether, and water. On dry distillation it gives  $\text{C}$ ,  $\text{As}$ , and naphthalene.

**Naphthalene arsonic acid**  $\text{C}_{10}\text{H}_7\text{AsO}(\text{OH})_2$ . [197°]. Needles. Formed by action of water on  $\text{C}_{10}\text{H}_7\text{AsCl}_2$ , which is obtained by treating  $\text{C}_{10}\text{H}_7\text{AsCl}_2$  with chlorine (W. Kelbe, *B.* 11, 1503).

**ASAFETIDA**. A gum-resin obtained by drying the juice contained in the root of *Ferula asafetida*, a Persian plant. Potash fusion gives resorcin and protocatechuic acid. Asafetida contains ferulic acid (*q. v.*), but its odour is due to 3 p.c. of an essential oil (135°–140°) which appears to be a mixture of  $\text{C}_{10}\text{H}_{16}\text{S}$  and  $\text{C}_{10}\text{H}_{14}\text{S}_2$ . Its alcoholic solution is ppd. by  $\text{HgCl}_2$  (Pelletier, *Bull. Pharm.* 3, 556; Johnston, *P. M.* Dec. 1838; Hlasiwetz, *A.* 71, 23).

**ASARITE**.—Impure asarone.

**ASARONE**  $\text{C}_{12}\text{H}_{16}\text{O}_2$ . [59°]. (296°). S.G. 1.165. Contained in the root of *Asarum europaeum*. Needles or plates; v. sol. alcohol, ether, and glacial  $\text{HOAc}$ , sl. sol. hot water (Blanchet & Soll, *A.* 6, 296; C. Schmidt, *A.* 53, 156; Bulle-row & Rizza, *B.* 17, 1159; *Bl.* [2] 43, 114; Po-leck, *B.* 17, 1415).

**ASCLEPIONE**  $\text{C}_{20}\text{H}_{24}\text{O}_2$ . [101°]. Extracted by ether from the coagulum got by heating the milky juice of *Asclepias syriaca*. Radiating crystals; insol. water and alcohol. Not attacked by boiling  $\text{KOH}$  aq (List, *A.* 69, 125; Gram, *C. C.* 1886, 735).

**ASEBOTOXIN**. *C.* 60.5 p.c.; *H.* 7.4 p.c.; *O.* 32.1 p.c. [120°]. A glucoside extracted by water from the leaves of *Andromeda japonica*. Brittle mass. The addition of conc.  $\text{HCl}$  to its alcoholic solution gives a blue colour (Eijkman, *Z.* 1, 224; *Ph.* [3] 13, 365). It is accompanied by a glucoside, asebotin  $\text{C}_{21}\text{H}_{26}\text{O}_{12}$ , crystallising in yellow needles [147.5°] and also by asebo-quercetin  $\text{C}_{21}\text{H}_{26}\text{O}_{11}$  and asebofuscin  $\text{C}_{18}\text{H}_{18}\text{O}_8$  (Eijkman, *J.* 1883, 1410; *R.* 2, 99, 200).

**ASH OF ORGANIC BODIES**.

The inorganic constituents contained in vegetable and animal products are usually determined by incineration of the substance, and determination of the weight and composition of the ash. The first question to be considered is—Does this ash accurately represent the inorganic constituents of the substance?

The sulphuric acid originally present is undoubtedly but imperfectly represented. The tendency to the reduction of sulphates to sulphides during ignition with carbonaceous, and especially with nitrogenous, matter, is generally overborne by the oxidation of the sulphur contained in the albuminoids. The sulphuric acid found in the ash is thus greater

than that originally present; it entirely fails, however, to represent the sulphur present in the original substance; this must be determined by a special experiment.

The carbonic acid originally present in the substance is generally quite undiscoverable by an analysis of the ash. Carbonic acid may be lost by the decomposition of calcium and magnesium carbonates during ignition; or by the decomposition of carbonates by the action of silica, or of phosphates containing less than three equivalents of base. On the other hand carbonates are produced when tribasic alkali phosphates are ignited with carbon; they are also formed in large quantity during the incineration of organic substances containing nitrates, or salts of organic acids. Treatment of an ash

Phosphoric acid may be lost if acid phosphates are heated to a high temperature with carbonaceous matter. The alkali metals are also liable under some circumstances to suffer loss by volatilisation.

The ash constituents are obtained with the smallest loss when the ignition is conducted at a low temperature, preferably in a muffle. In some cases an excess of lime or baryta must be added to prevent losses of phosphoric acid and chlorine; this treatment also prevents the fusion of the ash (Strecker, *J.* 73, 366).

1. ASH OF ANIMALS. —The proportion of ash in some of the principal parts and products of the animal body, and its percentage composition, are shown in the following table. The figures are taken from Wolff's *Aschen Analysen*

ASH OF ANIMAL PARTS AND PRODUCTS.

	Number of Analyses	Pure ash in 100 dry substance	100 parts of pure ash contain								
			K <sub>2</sub> O	Na <sub>2</sub> O	CaO	MgO	Fe <sub>2</sub> O <sub>3</sub>	P <sub>2</sub> O <sub>5</sub>	SO <sub>2</sub>	SiO <sub>2</sub>	Cl

\* These numbers represent per cent. of pure ash in fresh substance.

with ammonium carbonate, and re-ignition, is sometimes employed with the view of converting caustic lime and magnesia into carbonates. Such treatment converts stlphides and cyanides into carbonates; sulphate of calcium is also partially converted into carbonate if only a small proportion of alkali carbonate is present. Treatment with carbonic acid water is more free from objection, but its action is slow.

The chlorides found in an ash may be below the truth from volatilisation of alkali chlorides, if too high a temperature has been employed; or from loss of hydrochloric acid due to the action of organic acids produced during the charring of the organic matter; or from a similar action of silica, or dibasic phosphates, at a high temperature.

(1880), with the exception of the analysis of bone ash, which is quoted from *C. J.* 24, 80. The bone-ash represents the mean composition of all the carcase bones of the 'fat ox' analysed at Rothamsted. In this analysis, alkalis, and sulphuric and carbonic acids, were not determined; the whole amount of these constituents was, however, but 4.5 p.c. The 'pure ash' in Wolff's Tables is exclusive of sand, charcoal, and carbonic acid.

The amount of ash yielded by the entire bodies of the principal animals reared on the farm, and its composition, have been determined by Lawes and Gilbert (*T.* 1883. 865); they also separately analysed the ash of the carcase and offal parts. The percentage composition of the ash of the entire bodies of calf, ox, lamb, sheep,

*Properties*.—Slender needles, v. sl. sol. cold, m. sol. hot, alcohol.

*Reactions*.—1. Gives on oxidation benzoic acid and tri-phenyl-carbinol.—2. Heating with alcoholic KOH produces tri-phenyl-methane and benzoic acid (Zagumenny, *Bl.* [2] 31, 330). 3. Reduced by HI to *s*-tetra-phenyl-ethane (?).

**BENZPINACONE**  $C_{18}H_{12}O_2$  i.e.

$Ph_2C(OH).C(OH)Ph_2$ . Tetra-phenyl-ethylene glycol. [168°]. S. (benzene) 3-8 at 80°; S. (HOAc) 8-7 at 118°; S. (95 p.c. alcohol) 2-5 at 80°.

*Formation*.—From benzophenone by reducing the alcoholic solution with Zn and  $H_2SO_4$  (Linnemann, *A.* 133, 26) or a solution in acetic acid (10 pts.) diluted with water (2 pts.) with zinc (Zagumenny, *J. R.* 12, 426).

*Properties*.—Minute prisms, sl. sol. boiling alcohol, v. sol. ether. On fusion it splits up into benzhydrol and benzophenone (Thörner a. Zincke, *B.* 10, 1473).

*Reactions*.—1. Chromic acid oxidises it to benzophenone.—2. Sodium amalgam reduces it to di-phenyl-carbinol.—3. Readily converted into (a) or (b) benzpinacoline by dehydration; this is effected by  $BzCl$ ,  $AcCl$ , dilute acids, or even by recrystallisation from alcohol (Za.).—4.  $Ac_2O$  gives benzhydrol and benzophenone.—5. HI and P at 170° give tetra-phenyl-ethane (Graebe, *B.* 8, 1054).

**BENZ-URANIDOXIM**  $C_{11}H_{11}N$  i.e.

$C_6H_5C(NO)(NH.CO.NH_2)$ . [115°]. Formed by the action of potassium cyanate upon benzaniloxim hydrochloride in conc. aqueous solution (Falek, *B.* 19, 1186). Long thin white needles. V. sol. alcohol, ether, benzene, and ligroin, sl. sol. water.

**BENZ-URANILIDOXIM**  $C_{11}H_{11}N_2O_2$  i.e.

$C_6H_5C(NO)(NH.CO.NH_2)$ . [167°]. Formed by the action of potassium cyanate upon benzanilidoxim hydrochloride in concentrated aqueous solution (Müller, *B.* 19, 1671). Yellowish needles. Sol. alcohol, ether, benzene, and chloroform, insol. water.

**BENZYL**. The radicle phenyl-methyl,  $C_6H_5CH_2$ . It is isomeric with methyl-phenyl or tolyl  $CH_3C_6H_4$ .

**DIBENZYL** v. *s*-DI-PHENYL-ETHANE.

**BENZYL-ACETAMIDE** v. *Acetyl*-Benzyl-AMINE.

**BENZYL ACETATE**  $C_6H_5CH_2O.CO.CH_3$ . (206°). S.G. 1.057. From benzyl alcohol (2 vols.), acetic acid (4 vols.) and  $H_2SO_4$  (1 vol.), or by boiling benzyl chloride with alcoholic KOAc (Cannizzaro, *A.* 88, 130). Formed also by boiling a mixture of benzoic aldehyde and glacial acetic acid with zinc-dust (Tiemann, *B.* 19, 355). Oil, smelling of pears. Sodium acting upon benzyl acetate does not form benzyl aceto-acetate but the chief product is benzyl *s*-phenyl propionate:  $4C_6H_5CO.C_6H_5 + Na_2 = 2OH.CO.Na + 2C_6H_5CH_2.CO.C_6H_5 + H_2$ , and by a secondary reaction, sodic phenyl-propionate, sodic phenyl-acrylate, and toluene:

$2C_6H_5CH_2.CO.C_6H_5 + Na_2 = C_6H_5CH_2.CO.Na + C_6H_5CH_2CH_2.CO.Na + 2C_6H_5CH_3$  (Conrad a. Hodgkinson, *A.* 193, 300).

**BENZYL-ACETIC ACID** v.  *$\beta$ -PHENYL-PROPIONIC ACID*.

**Di-benzyl-acetic**  $C_{16}H_{14}O_2$  i.e.

$(C_6H_5CH_2)_2CH.CO_2H$ . Di-phenyl-isobutyric acid [88°]. Obtained by saponifying the ether, by heating di-benzyl-malonie ether with alcoholic KOH (Lellmann a. Schleich, *B.* 20, 439), or by heating di-benzyl-malonie acid (Bischoff a. Siebert, *A.* 239, 101).

*Properties*.—Prisms (from ligroin), sl. sol. cold water, v. sol. alcohol. Heated with soda-lime it gives di-benzyl-methane.

*Salts*.— $AgA'$ : trimetric prisms, sol. boiling water (Michael a. Palmer, *Ann.* 7, 70).— $BaA'$ .— $CaA'$ .aq.

*Ethyl ether*  $EtA'$ . (above 300°). Formed, together with *s*-phenyl-propionic ether by heating acetic ether with benzyl chloride and sodium (Lydia Sesemann, *B.* 6, 1086; Merz a. Weith, *B.* 10, 759).

**BENZYL-ACETO-ACETIC ETHER** v. p. 21.

**BENZYL-ACETONE**  $C_{11}H_{10}O$  i.e.

$C_6H_5CH_2CH_2.CO.CH_3$ . Methyl phenylethyl ketone. (236°). S.G. 1.089.

*Formation*.—1. By the dry-distillation of a mixture of calcium hydrocinnamate and calcium acetate; the yield is 33 p.c. (Jackson, *B.* 14, 890). 2. From benzyl-aceto-acetic ether by boiling with alcoholic KOH (Ehrlich, *A.* 187, 15).

*Properties*.—Oil. Combines with  $NaHSO_3$ , forming  $C_{11}H_{11}ONaHSO_3$ .aq. Oxidised by  $CrO_3$  to acetic and benzoic acids.

**BENZYL-ACETONE  $\gamma$ -CARBOXYLIC ACID** v. ACETYL-PHENYL-PROPIONIC ACID.

**Benzyl-acetone  $\alpha$ -carboxylic acid**  $C_{11}H_{10}O_3$  i.e.  $CO_2H.C_6H_5CH_2CH_2.CO.CH_3$ . [144°]. Obtained by boiling  $\alpha$ -carboxy-benzyl-aceto-acetic ether with baryta-water (Bülow, *A.* 236, 192). Slender needles (from water).

**BENZYL-ACETOXIM** v. ACETOXIM, p. 38.

**BENZYL-ACETYL-SUCCINIC ETHER** v. ACETYL-BENZYL-SUCCINIC ETHER, p. 39.

*p*-**BENZYL-DI-ACETYL-PYRROL** v. BENZYL-PYRROL-2,5-DI-METHYL-KETONE.

**BENZYL ALCOHOL**  $C_6H_5O$  i.e.  $C_6H_5CH_2OH$

Mol. w. 108. (206-5°). S.G. 1.0429 (Brühl) S. 4 at 17°.  $\mu_D$  1.5518.  $n_D$  53.16. H.F. 38.73 (Stohmann, *J. pr.* [2] 36, 4).

*Occurrence*.—Balsam of Peru contains benzyl benzoate, benzyl cinnamate and small quantities of benzyl alcohol (Kraut, *A.* 162, 129). Liquid storax contains benzyl cinnamate (Laubenheimer, *A.* 162, 285). Balsam of tolu contains benzyl cinnamate and some benzyl benzoate (Busse, *B.* 9, 830). In small quantity, together with benzoic aldehyde, prussic acid, and a resin in the volatile oil of cherry-laurel (Tilden, *Ph.* [3] 5, 761).

*Formation*.—1. Together with KOBz by the action of alcoholic KOH on benzoic aldehyde (Cannizzaro, *A.* 88, 129). 2. From benzyl chloride by converting it into benzyl acetate by alcoholic KOAc, and boiling the product with alcoholic KOH (Cannizzaro, *A.* 96, 216).—3. From benzyl chloride by heating with an aqueous solution of  $K_2CO_3$  (Meunier, *Bl.* [2] 38, 159); with water (10 pts.) and freshly ppd.  $Pb(OH)_2$  (3 pts.) (Lauth a. Grimaux, *A.* 143, 81); or merely with water (30 pts.) (Niederist, *A.* 196, 353).—4. From balsam of Peru by boiling with aqueous KOH (Kachler, *J. pr.* 107, 807).—5. By the action of sodium-amalgam upon

benzoic aldehyde (Friedel, *J.* 1862, 263), benzoic acid, hippuric acid (Hermann, *A.* 182, 76; 183, 335), benzoyl chloride in presence of HCl (Lippmann, *Bl.* (2) 4, 249), or benzamide (Guareschi, *G.* 4, 455).

**Preparation.**—10 pts. of benzaldehyde are shaken in a stoppered cylinder with a solution of 9 pts. of KOH in 6 pts. of water, and left to stand over-night. Sufficient water is then added to dissolve the potassium benzoate which has separated, and the solution is extracted with ether; after evaporating the ether the residue is distilled; the yield is 92 p.c. of the theoretical. Benzyl alcohol cannot be dried with  $\text{CaCl}_2$  as it combines with it (Meyer, *B.* 14, 2394).

**Properties.**—Liquid with little odour, al. sol. water, sol. alcohol and ether.

**Reactions.**—1. Oxidised by dilute  $\text{HNO}_3$  or air and platinum black to benzoic aldehyde, and by  $\text{CrO}_3$  to benzoic acid. 2. HI and P at  $140^\circ$  reduce it to toluene (Graebe, *B.* 8, 1054). 3. Alcoholic KOH forms toluene and benzoic acid (Cannizzaro, *A.* 90, 253). 4. Conc.  $\text{H}_2\text{SO}_4$ ,  $\text{P}_2\text{O}_5$ , and  $\text{ZnCl}_2$  form a resin (Cannizzaro, *A.* 92, 113). 5.  $\text{B}_2\text{O}_3$  at  $110^\circ$  forms di-benzyl oxide ( $\text{C}_6\text{H}_5\text{CH}_2\text{O}$ ). 6. Solid cyanogen chloride forms benzylcarbamate and di-benzyl-urea (Cannizzaro, *G.* 1, 83; *B.* 3, 517). 7. Urea nitrate at  $120^\circ$  forms di-benzyl-urea and benzoic aldehyde; at  $140^\circ$  it forms benzyl carbamate (Campisi a. Amato, *G.* 1, 39). 8.  $\text{BCl}_3$  forms *s*-di-phenyl-ethane and benzyl chloride (Cuncler, *B.* 10, 1655).

**Methyl ether**  $\text{C}_6\text{H}_5\text{CH}_2\text{OMe}$ . ( $168^\circ$ ). From benzyl chloride, KOH, and MeOH (Sintenis, *A.* 161, 334). Also from benzyl sulphide, methyl alcohol, and MeI (Cahours, *J. Ch.* 5, 10, 24).

**Ethyl ether**  $\text{C}_6\text{H}_5\text{CH}_2\text{OEt}$ . ( $185^\circ$ ). Gives anthracene when heated with  $\text{P}_2\text{O}_5$ . Chlorine in the cold forms HCl, ethyl chloride, and  $\text{C}_6\text{H}_5\text{CHO}$ ; at a higher temperature it gives  $\text{EtCl}$  and benzyl chloride. Chlorine in the cold in presence of I forms chloro-benzoic aldehydes and EtI (Sintenis, *A.* 161, 334). Br forms in the cold HBr, EtBr, benzyl bromide, benzoic aldehyde, and BzBr (Paterno, *B.* 5, 288).

**Isobutyl ether**  $\text{C}_6\text{H}_5\text{CH}_2\text{OOC}_4\text{H}_9$ . (c.  $210^\circ$ ) (Claus a. Trainer, *B.* 19, 3006).

**Phenyl ether**  $\text{PhOCH}_2\text{Ph}$ . ( $339^\circ$ ). ( $287^\circ$ ). From phenol-potassium, benzyl chloride and a little alcohol at  $100^\circ$  with inverted condenser for 3 hours (Stadel, *A.* 217, 44; Lauth a. Grimaux, *A.* 113, 81; Sintenis, *A.* 161, 337). Glistening white plates which feel greasy (from alcohol). Conc.  $\text{HCl}$  at  $100^\circ$  splits it up into phenol and benzyl chloride. Chlorine in presence of HgO forms the chloro-phenyl ether,  $\text{C}_6\text{H}_4\text{CH}_2\text{OOC}_6\text{H}_4\text{Cl}$  ( $71^\circ$ ); bromine forms similarly  $\text{C}_6\text{H}_4\text{CH}_2\text{OOC}_6\text{H}_4\text{Br}$  ( $60^\circ$ ).

***o*-Tolyl ether**  $\text{C}_6\text{H}_4\text{CH}_2\text{OOC}_6\text{H}_4\text{CH}_3$ . ( $12^\circ$ ). **Benzyl-o-cresyl ether**. ( $285^\circ$ – $290^\circ$ ) (Stadel, *B.* 14, 899).

***m*-Tolyl ether**  $\text{C}_6\text{H}_4\text{CH}_2\text{OOC}_6\text{H}_4\text{CH}_3$ . ( $13^\circ$ ). ( $48^\circ$ ). ( $300^\circ$ – $305^\circ$ ). Satiny tablets.

***p*-Tolyl ether**  $\text{C}_6\text{H}_4\text{CH}_2\text{OOC}_6\text{H}_4\text{CH}_3$ . ( $14^\circ$ ). ( $41^\circ$ ). From potassium *p*-cresol, a little alcohol, and benzyl chloride (Stadel, *A.* 217, 44). The yield is 86 p.c. White silky scales or transparent six-sided columns (from alcohol). Feels greasy.

**(*a*)-Naphthyl ether**. An oil, decomposed by distillation.

**(*\beta*)-Naphthyl ether**  $\text{C}_{10}\text{H}_7\text{OCH}_2\text{Ph}$ . ( $99^\circ$ ). From (*\beta*)-naphthol (70 g.), KOH (37 g.), a little water and alcohol, and benzyl chloride (70 g.). White plates (from alcohol). No smell. Not volatile with steam (Stadel, *A.* 217, 47).

Other benzyl ethers are described under the hydroxylated compounds from which they are derived.

#### BENZYL-*o*-AMIDO-ACETOPHENONE

$\text{C}_6\text{H}_5(\text{NHC}_6\text{H}_5)\text{COCH}_3$ . ( $81^\circ$ ). Formed by heating *o*-amido-acetophenone with benzyl chloride (Bayer, *B.* 17, 971). Large prisms. V. sol. alcohol, ether, benzene, chloroform and  $\text{CS}_2$ , sl. sol. ligroin. Weak base.

**Nitrosamine**  $\text{C}_6\text{H}_5(\text{N}(\text{C}_6\text{H}_5)\text{NO})\text{COCH}_3$ . ( $55^\circ$ ); long colourless needles. By heating with  $\text{H}_2\text{SO}_4$  it gives a mixture of indigo and benzyl-indigo.

#### BENZYL-*o*-AMIDO-BENZOIC ACID

$\text{C}_6\text{H}_5\text{NHCOCH}_2\text{CO}_2\text{H}$ . ( $176^\circ$  uncor.). Formed together with its formyl derivative by oxidation of benzyl-quinoline with alkaline  $\text{KMnO}_4$ . Long needles or thick prisms.

Salts  $\text{C}_6\text{H}_5\text{NO}_2\text{HCl}$ : ( $105^\circ$  uncor.); large tables. ( $\text{C}_6\text{H}_5\text{NO}_2$ ) $\cdot\text{HCl}\cdot\text{PtCl}_4$ : ( $158^\circ$  uncor.); orange yellow tables.

**Formyl derivative**  $\text{C}_6\text{H}_5\text{N}(\text{CHO})\text{C}_6\text{H}_5\text{CO}_2\text{H}$ . ( $196^\circ$ ); large colourless tables (Claus a. Glyckherr, *B.* 16, 1283).

#### BENZYL-AMIDO-TRI-PHENYL-METHANE

$\text{Ph}_3\text{C.NHCH}_2\text{Ph}$ . ( $110^\circ$ ). The hydrochloride  $\text{B}^+\text{HCl}$  ( $249^\circ$ ) is formed by the action of benzyl chloride on *o*-amido-tri-phenyl-methane (Elbs, *B.* 17, 703).

#### Di-benzyl-amido-di-phenyl-methane

$\text{Ph}_2\text{CH}_2\text{C}_6\text{H}_4\text{N}(\text{CH}_2\text{Ph})_2$ . From aniline hydrochloride and benzyl chloride at  $120^\circ$ . Also from acetanilide and benzyl chloride at  $120^\circ$ . White amorphous powder (Meldola, *C.* 20, 41, 200). Soluble in benzene. Solutions have a blue fluorescence.

#### BENZYLAMINE $\text{C}_6\text{H}_5\text{N}$ i.e. $\text{C}_6\text{H}_5\text{CH}_2\text{NH}_2$

Mol. w. 107. ( $184^\circ$ ). S.G.  $1.4$ – $1.9$ .

**Formation.**—1. Together with di- and tri-phenylamine by heating benzyl chloride with alcoholic  $\text{NH}_3$  (Cannizzaro, *A.* 134, 128; Lippmann, *A.* 144, 304). 2. Together with di- and tri-benzylamine by the action of Zn and HCl upon benzonitrile (Mendius, *A.* 121, 144; Spica, *G.* 10, 515). 3. By reducing thiobenzamide  $\text{C}_6\text{H}_5\text{CSNH}_2$  with Zn and HCl (Hofmann, *B.* 1, 102). 4. From benzyl cyanate and KOH (Strakosch, *B.* 5, 692). 5. By saponification of its acetyl derivative, obtained by the action of acetamide on benzyl chloride (Rudolph, *B.* 12, 1297). 6. By the action of bromine in alkaline solution on phenyl-acet-amide  $\text{C}_6\text{H}_5\text{CH}_2\text{CONH}_2$ ; the yield is 60 p.c. of the theoretical quantity (Hofmann, *B.* 18, 2738; Hoogewerf a. Van Dorp, *R. T. C.* 5, 252). 7. Together with toluene, by energetic reduction of hydrobenzamide dissolved in absolute alcohol by means of sodium or sodium-amalgam; very good yield (O. Fischer, *B.* 19, 748). 8. By reduction of an alcoholic solution of benzaldehyde-phenyl-hydrazide by means of sodium-amalgam and acetic acid (Tafel, *B.* 19, 1928). 9. By reduction of benzaldoxim (5 pts.), dissolved in alcohol (15 pts.), at  $50^\circ$ – $60^\circ$  with sodium-amalgam (160 pts. of  $2\frac{1}{2}$  p.c. Na), keeping acid by gradual addition of acetic acid: good yield (Goldschmidt,

## ASH OF ORGANIC BODIES.

and pig will be found below. The composition in 1,000 parts of the fasted live weight of the animal body is also given. The latter will afford data for calculating the loss which a farm suffers by sale of stock. The fasted live-weight is inclusive of contents of stomach and intestines, but the constituents of these contents are not reckoned among the animal constituents. The 'pure ash' is inclusive of carbonic acid.

2. ASH OF PLANTS. The composition of the ash of plants of agricultural importance will be given under the headings of the different crops, some general considerations will, however, be best made in the present place.

podiceae, and of silica by the *Equisetaceae* and *Graminaceae*.

The ash constituents which enter the circulation of the plant are (1) partly employed in the formation of new tissue; (2) partly deposited as incrusting matter on the older tissues; while (3) soluble salts that are of no advantage to the plant first accumulate in the sap, and then are gradually removed from the plant by the action of rain, and possibly by diffusion into the soil through the roots. The ash constituents most largely consumed in the formation of tissue are potash and phosphoric acid; in all the actively growing parts of a plant potash and phosphoric acid are greatly preponderate. Magnesia, lime,

Percentage Composition of Ash from Entire Bodies of Animals.

The ash constituents of a plant are obtained from the soil by the roots. All matters in the soil which are soluble and diffusible will enter the plant by the root, the abundant evaporation of water from the surface of a growing plant maintaining a rise of liquid in the capillary vessels. The substances entering the plant are not, however, limited to those existing in solution in the soil, as the roots of plants exercise a solvent or digestive action on constituents of the soil not otherwise soluble in water. The wide differences in the assimilating powers of the roots of different plants are well illustrated by the special assimilation of alumina by the *Lyc-*

oxide of iron, and sulphuric acid, must also be reckoned as essential for plant growth. The incrusting ash constituents are calcium salts and silica; these are chiefly precipitated in the leaves, where evaporation is most active. The soluble salts remaining unused in the sap generally contain a large proportion of chlorides, and of sodium salts.

A vigorous plant will take from a rich soil a much larger quantity of ash constituents, especially of alkali salts, than is necessary for its growth. For the same reason a plant growing on different soils may yield a very different ash. Thus a clover or bean plant will be rich in

potash or lime according as one or the other preponderates in the soil. On the other hand plants clearly exercise a selective power, potash being stored up in large quantity, though soda rather than potash may be abundant in the soil. This selective power is apparently not a property of the roots, but simply results from the fact that potash is removed from the sap to form tissue, while soda is not; potash salts can thus continue to enter the roots by diffusion or otherwise, while sodium salts having accumulated in the sap the tendency of diffusion is now for them to pass through the roots into the moist soil (see Dehérain, *Cours de Chimie agricole* [1873] 77). The Rothamsted experiments show that potash greatly preponderates in hay, and in barley straw, when the soil supplies a sufficient quantity; but when potash fails, soda is retained by the plant to a considerable extent.

The variations in the composition of the ash of any plant do not extend to the seed; the ash of this is of very definite composition whatever the nature of the soil. The ash of a seed consists chiefly of potassium phosphate; soda is practically absent.

While the seed is forming, a migration of phosphoric acid and potash, and of nitrogenous matter and carbohydrates, sets in from all parts of the plant, the roots included; a great part of these important constituents is finally stored in the seed. The extent to which the exhaustion of the plant, and the enrichment of the seed, proceeds, depends on the climate during the ripening period.

R. W.

#### ASPARAGINE

$C_4H_7N_2O_5$ , i.e.  $CO_2H.CH_2.CH(NH_2).CO.NH_2$  or  $CONH_2.CH_2.CH(NH_2).CO_2H$ . *Amido-succinic acid*. M. w. 150 (containing aq.) S.G.  $\frac{1}{4}$  1.52. S. c. 1.8 at 10.5°; 53 at 100°. Occurs in juice of most plants, especially in growing buds and germinating seeds (e.g. asparagus, marsh-mallow, comfrey, potatoes, deadly nightshade, chestnuts, liquorice root, lettuce, convolvulus root, dahlia tubers, young shoots of vetch, peas, beans, and other leguminous plants). Lupine seeds that have not begun to grow contain no asparagine; after 15 days' germination more than 20 p.c. of asparagine may be extracted by water (Schulze a. Barbieri, *J. pr.* [2] 27, 339). When twigs full of young leaf-buds of the plane, birch, or horse-chestnut are cut off and allowed to open by placing the cut end in water, the leaves are found to contain asparagine (S. a. B., *J. pr.* 133, 145). Asparagine may be formed by adding conc. ammonia to mono-ethyl aspartate (Schaul, *A.* 157, 24).

*Properties*.—Trimetric prisms (containing aq.) exhibiting left-handed hemihedry. Sol. water, acids, and alkalis; insol. alcohol and ether. Its solution in water or alkalis is levorotatory, in acids it is dextrorotatory. In HCl solution  $[\alpha]_D^{20}$  = about +36°; in aqueous solution about -6°; in ammoniacal solution about -11°.

*Reactions*.—1. Boiling with lime, or baryta-water, or with dilute  $H_2SO_4$ , rapidly converts it into aspartic acid.—2. Nitrous acid forms malic acid.—3. Impure asparagine is liable to undergo fermentation, changing to ammonio succinate. 4. MeI and KOH produce an amide of fumaric acid,  $CO_2H.CH:CH.CONH_2$  (Michael a. Wing, *Ann.* 6, 419; Griess, *B.* 12, 2117).

*Salts*.— $HA'HCl$ .— $(HA)_2.HCl$ .— $CuA'_2$ .— $CaA'_2$ .— $ZnA'_2$ .— $HA'HgCl_2$ .— $AgA'$ .— $HA'(AgNO_3)_2$ .— $HA'C_2H_5(NO_2)_2.OH$ : yellow prisms (Smolka, *M.* 6, 915).

*Estimation*.—Heat the extract containing it with dilute HCl for some hours and determine the amount of  $NH_4Cl$  formed. This corresponds to half the nitrogen in asparagine (Sachsse, *J. pr.* [2] 6, 118). Glutamine also splits off half its amidogen as ammonia when treated with HCl. Or the extract may be treated with bromine and NaOH (measuring evolved  $N_2$ ) both before and after heating with HCl (Sachsse). But asparagine gives off too much  $N_2$  when so treated (Morgen, *Fr.* 20, 37). It even gives off a little  $N_2$  when treated with NaBrO before heating with HCl. These two errors nearly balance one another (E. Schulze, *J. pr.* [2] 31, 235). Solutions of sodic aspartate give off no  $N_2$  with NaBrO, but if  $NH_3$  be present more  $N_2$  is evolved than corresponds to the  $NH_4$ . The increase may be 6 p.c. Leucine behaves in the same way as asparagine, but tyrosine behaves in exactly the opposite manner. Urea has the same influence as  $NH_3$ . It is therefore better to determine the free  $NH_4$  by distilling with  $MgO$ ,  $CaO$  or even NaOH (comp. Berthelot a. André, *C. R.* 103, 1051). The presence of peptones will, of course, invalidate the determination, these are often absent from vegetable solutions; if present they must be removed: albuminoids may be pptd. by lead salts, peptones by tannin or phosphotungstic acid (E. Schulze, *l.c.*).

#### Dextro-asparagine

$C_4H_7(NH_2)(CO_2H).CO.NH_2$ . Dextro-hemihedral crystals. Dextrorotatory  $[\alpha]_D^{20}$  = +5°41'. Very sweet taste (ordinary asparagine is tasteless). Rather more soluble in water than ordinary asparagine. Occurs in the mother-liquors obtained in recrystallising the crude asparagine prepared from the shoots of the vetch; 20 kilos of crude asparagine, obtained from 6500 kilos. of vetch gave 100 grms. of the pure dextro-asparagine.

The compounds prepared from dextro-asparagine exhibit the same properties as those prepared from the laevo-asparagine except that their rotatory power is reversed. By heating with 2 mols. of aqueous HCl at 170°-180° both asparagines give the same inactive aspartic acid (Piuetti, *C. R.* 103, 134; *B.* 19, 1691).

*Additional References*.—Vauquelin a. Robiquet, *A. Ch.* 57, 88; Dessaignes, *A.* 82, 237; Piria, *A. Ch.* [3] 22, 160; Pasteur, *A. Ch.* [3] 31, 70; Mercadante, *G.* 5, 187; Portes, *B.* 9, 1934; Dubrunfant, *J. pr.* 53, 508; Corup-Besanez, *A.* 125, 291; Champion a. Pellet, *B.* 9, 721; Becker, *B.* 14, 1031; De Luca a. Ubaldini, *C. R.* 59, 527; Buchner, *Z.* 1862, 117; Campani, *Z.* [2] 6, 87; E. Schulze, *B.* 15, 2855; *J. pr.* [2] 20, 397; 27, 339.

#### ASPARTIC ACID $C_4H_7NO_5$ , i.e.

$CO_2H.CH_2.CH(NH_2).CO_2H$ . *Amido-succinic acid*. Mol. w. 133. S.G.  $\frac{1}{4}$  1.66. S. 45 at 20°; 5.4 100°.

*Formation*.—1. By boiling asparagine with lime, baryta,  $PbO$ , KOH, or HCl dissolved in water.—2. By boiling albumen or casein with dilute  $H_2SO_4$  (Kreussler, *J. pr.* 107, 239; Ritt-hausen, *J. pr.* 107, 218).—3. By treating proteids with bromine (Hlasiwetz a. Habermann, *A.* 159, 325).—4. From casein by treatment

with  $\text{SnCl}_2$  and  $\text{HCl}$  (H. a. H., A. 160, 162).—5. From diazo-succinic ether by reduction with zinc dust and acetic acid (Curtius a. Koch, B. 19, 2460).

**Preparation:** 100 grms. of asparagine are boiled for 2 or 3 hours with an inverted condenser with 408 c.c. of pure aqueous hydrochloride (containing 11925 g.  $\text{HCl}$  per c.c.). To the cooled solution is then added 204 c.c. of aqueous  $\text{NH}_3$  (corresponding to the acid volume for volume). On standing for several hours the aspartic acid separates in colourless crystals. The yield is 90 p.c. of the theoretical (Schiff, B. 17, 2929).

**Properties.**—Small trimetric rectangular plates. Sl. sol. water, insol. alcohol. Its solutions in alkalis are levorotatory; its solution in  $\text{HCl}$  is dextrorotatory,  $[\alpha]_D = +28^\circ$ . The rotation is affected by the nature of the solution (Becker, B. 14, 1035). Aspartic acid (1 mol.) prevents the ppn. of  $\text{Cu}(\text{OH})_2$  (1 mol.) by  $\text{KOH}$ .

**Reactions.**—1. Nitrous acid converts it into malic acid.—2.  $\text{MeI}$  and  $\text{KOH}$  form fumaric acid (Korner a. Menozzi, R. Istit. Lombard. 13, 352).—3. Not affected by boiling water or by *magnesia*.—4. Heating in a current of  $\text{HCl}$  at  $130^\circ$ – $200^\circ$  produces two anhydrides: (a) insoluble in water ( $\text{C}_{12}\text{H}_{12}\text{N}_2\text{O}_{11}$ ), (b) slightly soluble in water ( $\text{C}_{16}\text{H}_{12}\text{N}_2\text{O}_{10}$ ). Both are converted by boiling baryta into aspartic acid; but when the former is heated for 2 hours at  $125^\circ$  with half its weight of urea it produces a gummy mass, soluble in water forming a solution that has all the characters of a proteid. It is ppd. by acids, by  $\text{NaCl}$ ,  $\text{MgSO}_4$ , tannin, and  $\text{H}_2\text{Cl}_2$  forming gelatinous pps.  $\text{CuSO}_4$  and  $\text{KOH}$  give a violet solution (Grimaux, C. R. 93, 771).

**Salts.**— $\text{H}_2\text{A} \cdot \text{HCl}$ : deliquescent crystals.— $\text{H}_2\text{A} \cdot \text{H}_2\text{SO}_4$ — $\text{NaHA}$  aq.: trimetric prisms; S. 89 at  $12^\circ$ .— $\text{BaHA}$  2.4aq.— $\text{BaA}$  3aq.— $\text{CaA}$  4aq.— $\text{HgA}$ — $\text{PbHA}$ — $\text{AgHA}$ — $\text{Ag}_2\text{A}$ — $\text{CuA}$  4.1aq. S. 0.35 at  $15^\circ$ ; .43 at  $100^\circ$ ; v. sol. dilute  $\text{HIOAc}$ . The insolubility of this salt may be used to detect and to isolate aspartic acid (Hoffmeister, Sitz. B. 75, 469).— $\text{CuA}$  3aq (Curtius a. Koch, B. 19, 2460).

**Mono-ethyl ether  $\text{A}^m\text{EtH}$ .** Its hydrochloride ( $\text{A}^m\text{EtH} \cdot \text{HCl}$ ) forms large colourless needles, [199°].

**Di-ethyl ether  $\text{A}^m\text{Et}_2$ .** Its hydrochloride  $\text{A}^m\text{Et}_2 \cdot \text{HCl}$  forms excessively hygroscopic concentric needles.

**Di-methyl ether  $\text{A}^m\text{Me}_2$ .** Its hydrochloride  $\text{A}^m\text{Me}_2 \cdot \text{HCl}$  forms very hygroscopic glistening prisms (Curtius a. Koch, B. 18, 1293).

#### Amide v. ASPARAGINE.

**Di-phenyl amide**  
 $\text{CO}_2\text{H} \cdot \text{C}_6\text{H}_4 \cdot \text{NH}_2 \cdot \text{CONPh}_2$  [230°]. Formed, together with phthalimide, by the action of  $\text{NH}_3$  on the diphenylamide of phthalyl-amido-succinic acid  $\text{CO}_2\text{H} \cdot \text{C}_6\text{H}_4 \cdot \text{N}(\text{C}_6\text{H}_4 \cdot \text{C}_6\text{H}_4)_2 \cdot \text{CONPh}_2$  (Piutti, G. 16, 14).

**Inactive aspartic acid  $\text{C}_4\text{H}_7\text{NO}_4$ .** S. 42 at  $7^\circ$ .

**Formation.**—1. By the action of boiling  $\text{HCl}$  on the product obtained by heating the acid ammonium salts of malic, maleic or fumaric acid.—2. By heating an aqueous solution of the hydrochloride of active aspartic acid for several hours at  $170^\circ$  (Michael a. Wing, B. 17, 2984; Am. 7, 278).

**Properties.**—Monoclinic needles. Converted by nitrous acid into inactive malic acid.

#### Salts.— $\text{PbA}$ — $\text{Ag}_2\text{A}$ — $\text{H}_2\text{A} \cdot \text{HCl}$ .

**Lævo-aspartic acid  $\text{C}_4\text{H}_7\text{NO}_4$ .** Obtained from dextro-asparagine by treatment with  $\text{HCl}$  (Piutti, B. 19, 1693). Levorotatory. Its properties are the same as those of the dextrorotatory acid. Combines with dextro-acid to form an inactive modification.

**Additional References.**—Plisson, A. Ch. 40, 303; 45, 315; Boutron-Chaudard a. Pelouze, A. Ch. 52, 90; Liebig, P. 31, 232; A. 26, 125, 161; Wolff, A. 75, 293; Piria, A. Ch. [3] 22, 160; Dessaignes, C. R. 30, 324; 31, 432; A. 83, 83; J. Ph. [3] 32, 49; Pasteur, A. Ch. [3] 34, 30; A. 82, 324; Pott, J. pr. [2] 6, 91; Radziszewski a. Salkowski, B. 7, 1050; Ritthausen a. Kreussler, J. pr. [2] 3, 314; Scheibler, J. Ph. [4] 4, 152; B. 2, 236; Kreussler, Z. [2] 6, 93.

**ASPHALT.** A natural product of the decomposition of vegetable substances. It is found on the shores of the Dead Sea, also in a molten state in Trinidad, and as a mineral deposit at Seyssel. It frequently impregnates other rocks. When distilled with water, *petroleum*  $\text{C}_{10}\text{H}_{12}$  ( $280^\circ$ ), S.G. 0.89, V.D. 9.5, passes over (Houssingault, A. Ch. [2] 64, 141; Voelckel, A. 87, 139).

**ASPIDOSAMINE  $\text{C}_{22}\text{H}_{30}\text{N}_2\text{O}_2$ .** [c.  $100^\circ$ ]. In quebracho bark (Hesse, A. 211, 263). Turns yellow in air. V. e. sol. ether, chloroform, benzene or alcohol, v. sl. sol. light petroleum, insol. water. Its alcoholic solution turns litmus blue, neutralises  $\text{HCl}$  and tastes bitter.

**Reactions.**—1. Solution of hydrochloride gives with  $\text{Fe}_2\text{Cl}_6$  a brownish-red colour.—2. Conc.  $\text{H}_2\text{SO}_4$  gives a bluish solution.—3. Conc.  $\text{H}_2\text{SO}_4$  and  $\text{MoO}_3$  gives a blue liquid.—4. Conc.  $\text{H}_2\text{SO}_4$  and  $\text{K}_2\text{Cr}_2\text{O}_7$  gives a dark blue colour.—5. Boiling aqueous  $\text{HClO}_4$  gives a magenta colour.

**Platinochloride.**  $\text{B}_2\text{H}_2\text{PtCl}_3\text{aq}$ .

**ASPIDOSPERMATINE  $\text{C}_{22}\text{H}_{30}\text{N}_2\text{O}_2$ .** [162°]. In quebracho bark (Hesse, A. 211, 259). Crystalline. V. sol. chloroform, alcohol, or ether. In alcohol (97 p.c.) it turns litmus blue, has a bitter taste, and is levorotatory  $[\alpha]_D = -72.3^\circ$  at  $15^\circ$  in a 2 p.c. solution.

**Reactions.**—1.  $\text{HClO}_4$  gives a magenta colour. 2. Conc.  $\text{H}_2\text{SO}_4$  and  $\text{K}_2\text{Cr}_2\text{O}_7$  give no colour.—3.  $\text{Fe}_2\text{Cl}_6$  gives no colour.

**Salts.**—Dilute  $\text{HCl}$  is neutralised by aspidospermatine.  $\text{NaOH}$  or  $\text{NH}_3$  give in the solution a flocculent pp. (m. sol. pure water) which soon becomes crystalline. Salts are amorphous.— $(\text{F}^1\text{HCl})_2\text{PtCl}_4\text{aq}$ .

**ASPIDOSPERMINE  $\text{C}_{22}\text{H}_{30}\text{N}_2\text{O}_2$ .** [206°]  $[\alpha]_D$  (alcohol)— $100.2^\circ$ ; (chloroform)— $83.6^\circ$ ; (dilute  $\text{HCl}$ )— $62^\circ$  (in all cases 2 p.c. solution at  $15^\circ$ ). S. (alcohol) 2 at  $14^\circ$ ; (ether) 74 at  $14^\circ$  (Wulfsberg, Ph. [3] 11, 269). An alkaloid present (with others) in bark called in the Argentine Republic quebracho blanco or quebracho Colorado (Fraude, B. 11, 2189; Hesse, A. 211, 251; Arata, C. J. 40, 622). Needles or pointed prisms (from alcohol or light petroleum). M. sol. alcohol, sl. sol. ether or light petroleum, v. sol. benzene or chloroform. Levorotatory.

**Reactions.**—1.  $\text{HCl}$  and  $\text{PtCl}_4$  give a blue pp.—2.  $\text{HClO}_4$  gives a magenta colour.—3. Conc.  $\text{H}_2\text{SO}_4$  no colour.—4. Conc.  $\text{H}_2\text{SO}_4$  and  $\text{MoO}_3$  no colour.—5. Conc.  $\text{H}_2\text{SO}_4$  and  $\text{K}_2\text{Cr}_2\text{O}_7$  a brownish-red turning dark green.—6. Salts give with

$\text{NH}_3$ ,  $\text{NaOH}$ ,  $\text{Na}_2\text{CO}_3$ , or  $\text{NaHCO}_3$ , a white flocculent pp. becoming crystalline.

**Salts.**—Very unstable; even ether or  $\text{CHCl}_3$  can partly decompose them.— $\text{B}_2\text{H}_6\text{PtCl}_4$ , 4aq.

**ASSAMAR.** A name given by Reichenbach (A. 49, 3) to a bitter, deliquescent, transparent yellow solid which may be extracted by alcohol from toasted bread. It is insol. ether. The same name was given by Vöckel (A. 85, 74) to a thick yellow neutral syrup obtained from the aqueous portion of the product of the distillation of cane-sugar. It is sol. ether. Both substances reduce aqueous  $\text{AgNO}_3$ .

**ASYMMETRIC CARBON.** A name applied to an atom of carbon that is united to four different atoms or radicles. All compounds that in the liquid state or in solution rotate light contain asymmetric carbon (Van 't Hoff, *La chimie dans l'espace*; Le Bel, *Bl.* [2] 22, 337).

**ATHAMANTA, OIL OF.**  $\text{C}_{10}\text{H}_{16}\text{O}$ . (163°). S.G. .84. An essential oil obtained from the leaves of *Athamanta oroselinum*. It forms a liquid compound with  $\text{HCl}$  (190°) (Schnedermann A. 51, 336).

**ATHAMANTIN**  $\text{C}_{11}\text{H}_{18}\text{O}_2$ . [79°]. In the root and seeds of *Athamanta oroselinum*. Fibrous, silky crystals, or sometimes rectangular prisms; insol. water, v. sol. alcohol and ether. It gives valeric acid on dry distillation. Aqueous acids and alkalis split it up into valeric acid and oroselone  $\text{C}_{11}\text{H}_{18}\text{O}$ . Chloro-, and tri-nitro-, athamantin are amorphous (Schnedermann, A. 51, 315; Geiger, A. 110, 359).

**ATHEROSPERMINE** [128°]. An alkaloid in the bark of *Atherosperma moschatum*. A greyish-white powder with bitter taste. V. sl. sol. water, m. sol. alcohol, sl. sol. ether. The solution of its hydrochloride gives pps. with phosphomolybdic acid, picric acid, tannin, and  $\text{PtCl}_4$ . It liberates iodine from iodic acid (Zeyer, J. 1861, 769).

**ATMOSPHERE.** The word *Atmosphere* ( $\alpha\tau\mu\sigma\phi\acute{\alpha}\rho\alpha$ , vapour;  $\sigma\phi\alpha\iota\tau\alpha$ , a globe) in its most extended sense signifies the gaseous envelope which surrounds any liquid or solid body: more commonly, however, it is taken to mean the invisible elastic fluid which surrounds the earth. A variety of phenomena, e.g. solar and terrestrial radiation, animal and vegetable life, weather, the disintegration of rocks and the formation of soils, the propagation of sound, &c., are dependent on the existence of a terrestrial atmosphere. The earth is not the only planetary body which possesses an atmosphere. The Sun, Jupiter, Mars, Saturn, have doubtless very dense atmospheres, but as yet we have no exact knowledge of their physical and chemical natures.

The phenomena of solar eclipses, and the facts that a single star seems to disappear instantly when it is occulted opposite the smooth part of the moon's limb, and that there is no change of colour or other effect such as a refractive atmosphere would occasion, make it certain that the moon's atmosphere, if it exists at all, must be of extreme tenuity. This conclusion is strengthened by evidence afforded by the spectroscope. It has been observed that the spectrum of the moon's light is identical with the solar spectrum and there is no trace of any absorptive action; moreover, it is found that

the spectrum of a star during its occultation disappears as suddenly as the star itself.

Wollaston's arguments as to the finite extent of the terrestrial atmosphere were deemed inconclusive even by his contemporaries. There is indeed direct evidence for the belief that air is present in a state of sensible density at much greater heights than 40 or 45 miles which was the limit Wollaston assigned. Liais, from observations on the phenomena of sunlight at Rio Janeiro, arrived at a superior limit of 200 miles; and Secchi, from observations on luminous meteors, calculated that air exists of appreciable density even at a height of 200 kilometres above the earth's surface. It is in fact probable that no actual limit exists. Up to the present it has been impossible to arrive at direct results otherwise than by astronomical observations, as the law of the diminution of temperature which in great measure governs the extent of the repulsion among gaseous particles is unknown for the upper strata of the atmosphere. No arguments can be based on the finite expansibility of gases. Faraday's experiments on the limits of vaporisation of mercury have been converted by Merget. It is obvious that the relative distribution of the mass of the air will be modified by the increase of attraction at the poles as compared with that at the equator; by the increase of temperature as we approach the torrid zone; and by the earth's motion.

The ponderability of air although suspected before the time of Aristotle was first conclusively demonstrated by Galileo, who found that a copper ball containing condensed air weighed more than when filled with air of ordinary tension. The weight of 1 litre of air, freed from aqueous vapour, carbonic acid, and ammonia, at 0° C., and under a pressure of 0.76 m. of mercury, at Paris (lat. 48° 50'), and at a height of 60 m. above the sea level, was found by Regnault to be 1.293187 grams. According to Regnault 1 litre of oxygen at the normal temperature and pressure weighs 1.429802 grams; 1 litre of nitrogen under the same conditions weighs 1.256167 grams. If  $x$  be the volume of oxygen contained in 1 litre of air, and  $1-x$  that of the nitrogen, then  $1.429802x + (1-x) 1.256167 = 1.293187$ , whence  $x = 0.2132$  or in per cents. 21.32, which is considerably higher than that found by eudiometric analysis. According to Magnus 1 litre of pure air at 0° and .76 m. weighs at Berlin (lat. 52° 36') 1.29306 grams. Ph. v. Jolly found that at Munich (lat. 48° 8', 515 m. above the sea's level) 1 litre of oxygen at 0° and .76 m. weighed 1.429094 grams; and 1 litre of nitrogen under the same conditions weighed 1.257614 grams. Reducing these numbers to the lat. of Paris and to a height of 60 m. above the sea's level, they become:

	Jolly	Regnault
Oxygen	1.429388	1.429802
Nitrogen	1.257873	1.256167

The *Bureau International des Poids et Mesures* adopts for the weight of 1 litre of dry air under a normal barometric height of 1 mm. and at the normal temperature  $\tau$

$$\text{Pri} = \frac{1.293052}{1 + 0.00367 + \frac{1}{760}}$$

on the assumption that the air contains .0001

parts of carbonic acid, and that '00867 is the coefficient of expansion of air at constant pressure for a normal degree.

This expression is obviously only true for a particular ratio of oxygen and nitrogen. The composition of the air varies sufficiently to affect its value at different times (Ph. v. Jolly, W. 6, 520).

The pressure exerted by the atmosphere upon the earth's surface, at the sea's level or upon any substance at that level, may be expressed by saying that it is equivalent to a barometric column about 76 centimetres (29·92 inches) high. Now at ordinary temperatures 1 c.c. of mercury weighs 13·58 grams. If we suppose that the base of the mercurial column is 1 sq. centimetre it follows that the weight of the counterbalancing atmospheric column is  $76 \times 13·58 = 1032$  grams. This is equivalent to 14·73 lbs. upon a sq. inch. It can be readily calculated that the total weight of the atmosphere of this average pressure is about  $11\frac{1}{2}$  trillions of pounds, or  $5\frac{1}{2}$  trillion kilos. Allowing for the space occupied by the land above the sea's level, the mass of the atmosphere may be taken as  $\frac{1}{120000}$  part of that of the earth (Herschel).

The heights of the counterbalancing columns of air and mercury will of course be in the same ratio as the weights of equal volumes if it be assumed that the air is of uniform tension throughout. The height of this homogeneous atmosphere is between five and six miles: it was first calculated by Robert Boyle to disprove the conjectures of Kepler and others that the air could not extend beyond a couple of miles or so from the earth's surface.

As the air is an elastic fluid it follows from Boyle's law that its pressure must diminish as we ascend; hence the mercurial column stands lower on a mountain top than in the valley below. The fact that the barometric column is less on the top of an elevation than at the bottom was first noticed in 1643 by Claudio Bereguardi from observations on the tower of Pisa—that is, five years before Perrier made his famous experiments on the Puy-de-Dôme. The relation between the pressure and density of the air at different altitudes may be seen from the following table:—

Metres above sea level	Bulk of air	Density	Barometer mm.
0	1 cub. metro	1·	760
5,520	2	0·5	380
11,040	4	0·25	190
16,560	8	0·125	95
22,080	16	0·0625	47·5
27,600	32	0·0312	23·8

A pressure equivalent to the average pressure of the atmosphere at the level of the sea is frequently adopted by engineers and others as a *unit of pressure* and is styled an *atmosphere*. In this country an atmosphere is the pressure equal to 29·905 inches of mercury at 32° F. at London, and is about 14·73 lbs. on the sq. inch. In the metric system it is the pressure of 760 mm. (29·922 inches) of mercury at 0°C at Paris, and is equal to 1·033 kilos on a

sq. centimetre. Hence the English 'atmosphere' is 0·99968 that of the metric system.

That the mercury in the Torricellian tube, or *barometer* as it was termed by Boyle, is constantly varying in height even at the same place, and that these variations are due to the fluctuating pressure of the atmosphere, appears to have been first clearly recognised by Descartes and by Boyle in 1658. It is, however, only within the last few years that we have acquired any very definite information respecting the distribution of the mass of the atmosphere over the earth. The pressure of the air at any given spot depends upon its relative position on the earth's surface: at this spot it varies also with the season of the year and the hour of the day. According to Buchan, whose isobaric charts are really the foundation of our exact knowledge of the subject, there are two broad belts of high pressure passing completely round the globe, one to the north and the other to the south of the equator. The southern belt of high pressure is nearly parallel to the equator; but the northern belt is more irregular in outline in consequence of the unequal distribution of land and water in the northern hemisphere. Between them is the low pressure of the tropical regions, through the centre of which is a narrow belt of still lower pressure towards which the north and south trades blow. A region of low pressure exists also round each pole; that round the north pole having two distinct centres, one in the north Atlantic, the other in the Pacific: at each of these the diminution of pressure is much below the average of the north polar depression. As regards the seasons, it is found that in January the highest pressures are over the continents of the northern hemisphere, and the lowest pressures are over the northern portions of the Atlantic and Pacific, S. America and S. Africa, and the Antarctic Ocean. The maximum mean pressure at this time is found in Central Asia where it is 30·4 inches, the minimum is in the N. Atlantic and round Iceland, where it is only 29·34 inches. The area of high pressure passes westwards through central and southern Europe, over the N. Atlantic between the parallels of 5° and 45°, across N. America (except to the North and North West), and over some portion of the Pacific. In July the mean pressure of Central Asia is only 29·468 inches or one inch less than in January. The lowest pressures of the western hemisphere are now to be found over the continents, whilst the highest are over the ocean between 50° N. lat. and 50° S. lat. Pressures are also higher at this time over S. Africa and Australia.

Speaking generally, atmospheric pressure is more regular throughout the year over the ocean than over the land. To the westward of each continent there is at all seasons an area of higher pressure over the ocean than over the land, in amount varying from 0·1 to 0·3 inch. These regions of high pressure extend over about 30° of longitude and attain their maxima during winter. The prevailing winds and the general circulation of the atmosphere are intimately associated with these areas of high and low pressure. Winds, in fact, are caused by the flowing away of air from regions of high pressure to those of low pressure, in accordance

with Buys-Ballot's law, which has been thus expressed by Buchan. 'The wind neither blows round the space of lowest pressure in circles returning on themselves, nor does it blow directly towards that space, but it takes a direction intermediate, approaching, however, more nearly to the direction and course of circular curves than of radii to a centre. More exactly the angle is not a right angle, but from  $45^\circ$  to  $80^\circ$ .'

The most important of the influences affecting atmospheric pressure during the months are temperature, and, as a secondary effect of temperature, humidity. By comparing the average pressure during the two months which exhibit the greatest divergence of temperature, viz. January and July, Buchan finds the following general result:—The January pressure exceeds that in July over the whole of Asia except in the north east, the highest pressures being near the middle of the continent; over Europe to the south and east of a line drawn from the north of Russia to the south of Norway, thence to the north coast of Germany, across France to Bordeaux, along the north of Spain, and passing out into the Atlantic at Corunna; over N. America except in the N. East and N. West. The July pressure exceeds that in January over the whole of the southern hemisphere, over the northern portion of the N. Atlantic, and over the northern part of the Pacific. The pressure which is thus removed from Asia, Europe, and America in the northern hemisphere in July is transferred partly to the southern hemisphere, and partly to the more northerly portions of the Atlantic and Pacific Oceans.<sup>1</sup>

At all places on the earth's surface where the alternation of day and night exists, the pressure of the atmosphere exhibits a remarkable diurnal variation. Generally speaking, the pressure is highest at about 9 A.M. and 9 P.M., and lowest at about 3 A.M. and 3 P.M., but the exact times vary somewhat with the locality and with the season of the year. The regularity of this variation within the tropics is so great that, as Humboldt remarked, the hour of the day may be approximately ascertained from the height of the mercurial column. This oscillation in atmospheric pressure is not confined to the sea's level: it takes place with equal regularity at heights of 13,000 feet. Within the tropics the oscillation amounts to about 2.2 mm., but as we approach the poles it decreases, until at  $70^\circ$  N. lat. it is only 0.3 mm. In our latitudes these hourly variations are much less strongly marked than in the tropics, and are usually masked by climatic disturbances; but by comparing the results of a large number of observations, the fluctuation, which in these islands amounts to about 0.5 mm. on the mean of the year, can be clearly made out. In Paris eleven years' observation shows that the mean barometric oscillation amounts from 9 A.M. to 3 P.M. to 0.756 mm., and from 3 P.M. to 9 P.M. to 0.373 mm. The amount of the diurnal variation differs during the seasons of the year, being greater in summer

than in winter. This peculiar phenomenon has given rise to much discussion, but as yet the cause cannot be said to be satisfactorily determined. Unlike the oceanic tide, it cannot be ascribed to the influence of the moon, since Bouvard has shown that the portion of the hourly oscillation of the pressure of the atmosphere which depends on the attraction of the moon cannot raise the mercury in the barometer at Paris more than 0.018 mm., whilst the total variation deduced from the 11 years' observation amounts to 1.129 mm. The fact that the two maxima of pressure occur when the temperature is about equal to the daily mean, and the two minima when the temperature is at its highest and lowest, has led to the supposition that the fluctuations in pressure are connected with the daily march of temperature, and also with the humidity of the air. Dove, Sabine, and Hopkins have offered explanations based on such connections, but they are insufficient to account for the facts. Lamont and Brown have sought to refer the phenomenon to the magneto-electric influence of the sun, or in other words to connect it with the cause of the diurnal changes in terrestrial magnetism. There is every reason for supposing that the cause of the diurnal variation in atmospheric pressure is in some way dependent on, or originates with, the sun, but that its effects are greatly modified by a variety of local or accidental circumstances, as for example the prevailing winds, the amount of moisture in the air, and the relative distribution of land and water.

The atmosphere appears to receive its heat (1) from the direct rays of the sun, (2) by the reverberation of those rays from the surface of the earth, (3) by contact with the ground, and (4) through the influence of aqueous vapour.

Although the air is not absolutely diathermanous, the heat received by the air from the direct rays of the sun is the least important of the sources enumerated. We know very little at present as to whether the diathermancy of air varies with its density: that is, we have little evidence to determine whether the absorption of the sun's rays increases as they pass further into an atmosphere compressed by its own weight.

The greater portion of the heat which finds its way into the atmosphere is due to radiation from the earth's surface and to the air being in contact with the ground. The amount of heat thus sent into the air depends to a great extent on the nature of the soil which receives the solar radiations and on its capacity for retaining heat. Hence places in the same latitudes and not very far distant from each other, and in the same condition as regards protection, may have very different mean temperatures on account of the different capacities of various soils for absorbing and retaining heat.

Aqueous vapour is one of the most important agents in modifying the temperature of the atmosphere. A relatively large amount of heat is rendered latent in the process of evaporation from the surface of the earth, and becomes sensible on the condensation of the vapour in the upper regions of the air. Aqueous vapour also acts even when in the condition of a perfect gas

<sup>1</sup> For further details see Buchan, 'The mean pressure of the Atmosphere and the prevailing Winds over the Globe for the Months of the Year' (*T.E.* 25); also Julius Hann's *Erkundung*; and R. H. Scott's *Elementary Meteorology*.

by retarding the transmission of the sun's rays through the air. As the quantity of aqueous vapour decreases as we ascend through the atmosphere, it follows that the amount of this absorption increases as the sun's rays penetrate further into the atmosphere.

The temperature of the atmosphere varies with a multitude of causes, such as the latitude, the season of the year, the hour of the day, the degree of humidity, &c. Among the causes which tend to raise the temperature of the air may be enumerated: the proximity of a western coast in the temperate zone; the divided configuration of a continent into peninsulas with deeply indented bays and inland seas; the aspect or position of a portion of the land with reference either to a sea of ice spreading far into the polar circle, or to a mass of continental land of considerable extent lying in the same meridian, either under the equator or at least within a portion of the tropical zone; the prevalence of southerly or westerly winds on the western shore of a continent in the temperate northern zone; chains of mountains acting as protecting walls against winds coming from colder regions; the infrequency of swamps which in the spring and beginning of summer long remain covered with ice; and the absence of woods in a dry sandy soil; finally the constant serenity of the sky in the summer months; and the vicinity of an oceanic current bringing water which is of a higher temperature than that of the surrounding sea.

On the other hand, the following causes lower the temperature of the air of a place: elevation above the level of the sea, when not forming part of an extended plain; the vicinity of an eastern coast in high and middle latitudes; the compact configuration of a continent having no littoral curvatures or bays; the extension of land towards the poles into the regions of perpetual ice without the intervention of a sea remaining open in the winter; a geographical position in which the equatorial and tropical regions are occupied by the sea, and consequently the absence under the same meridian of a continental tropical land having a strong capacity for the absorption and radiation of heat; mountain chains whose form and direction impede the access of warm winds; the vicinity of isolated peaks occasioning the descent of cold currents of air down their declivities; extensive woods which hinder the insolation of the soil by the vital activity of their foliage, which produces great evaporation owing to the large surface it exposes, and increase the surface that is cooled by radiation, acting consequently in a three-fold manner—by shade, evaporation, and radiation; the frequency of swamps or marshes which in the north form a kind of subterranean glacier in the plains lasting till the middle of summer; a cloudy summer sky which weakens the action of the solar rays; and finally a very clear winter sky favouring the radiation of heat (Humboldt: *Recherches sur les Causes des Inflexions des Lignes Isothermes*. See also Mohn's *Grundzüge der Meteorologie*).

The temperature of the air varies in different strata of the mass, decreasing generally after a certain elevation in proportion as the distance

from the earth's surface increases, but it is not possible to connect the diminution in temperature with the elevation in accordance with any definite law. It is usually assumed that the temperature falls about  $1^{\circ}\text{C}$ . for every 300 feet of perfectly dry air. As, however, the air invariably contains moisture, which is condensed by cooling and so produces heat, the decrement may be taken practically at about  $1^{\circ}\text{C}$ . for every 500 feet. This estimate can only be taken as an extremely rough approximation, for it is obvious that the rate of cooling must be affected by a great variety of causes. Indeed the extensive series of aeronautical observations made at the instance of the British Association showed such great irregularities in the rate of diminution that Mr. Glaisher concluded that no law exists.

The atmosphere always contains free electricity, which is generally positive, that is, of an opposite kind to that of the earth. Atmospheric electricity increases rapidly after sunrise, and reaches its first maximum for the day at about 8 A.M. In general the variation in potential follows the diurnal range of atmospheric pressure. In summer the hours of maxima appear to be 8 A.M. and 10 P.M. and the minima 4 A.M. and 4 P.M. In winter the hours of maximum intensity are 9 A.M. and 10 P.M. and the minima 4 A.M. and 4 P.M. This diurnal variation seems to depend mainly on the degree of humidity of the air, the humid months manifesting the greatest potential. The potential seems to increase from July to January, and then to decrease. According to Everett, the maxima occur in February and October, and the minima in June and November.

In clear weather the air is usually positively electrified; it is only during rain, or more properly speaking when rain begins, that the electricity is negative. On the approach of a storm the air is almost invariably negatively electrified, even when the storm-clouds are at a considerable distance from the place of observation. When rain begins, the drops show negative electricity like the air. In light rain the potential is moderate, but heavy rain is almost invariably accompanied by a high potential. Dellmann's observations have shown, however, that the air may have a very high potential, extending over many days, without any other evidences of an approaching storm.

The sources from which the electricity of the atmosphere is derived are not clearly recognised. De la Rive attributed it mainly to chemical action at work on the earth; Pouillet to the evaporation of water; Volta and Saussure to the inequalities of atmospheric temperature. In all probability atmospheric electricity is not wholly due to any one of these causes: they may all be regarded as contributing to the amount.

The sun's light in its passage to the earth is partially absorbed and reflected by the atmosphere. Clausius has calculated that of the direct sunlight entering the atmosphere on a clear day 6.4 p.c. is absorbed, 18.6 is reflected and diffused, leaving therefore 75 p.c. to reach the earth. This light is, of course, refracted in its passage in amount depending upon the density of the air. Each ray entering the atmosphere otherwise than perpendicularly may be

supposed to describe a curve in coming to the earth, and as objects are seen in the tangent of the curve on entering the eye, all celestial bodies not in the zenith appear further removed from the horizon than they actually are.

The refractive power of dry air free from carbonic acid is the mean of the refractive powers of the oxygen and nitrogen under the pressure which each gas exerts in the mixture. This fact furnishes a proof of the physical nature of the atmosphere; since, as Dulong has shown, the refractive power of a compound gas is not equal to the refractive powers of its components, but is sometimes greater and sometimes less. Moist air is rather less refractive than dry air: precipitated vapour, as mist or fog, slightly increases the refractive power.

Although many of the more striking physical properties of the air were recognised even in the earliest ages, it is only within comparatively recent time that anything very definite has been known concerning its chemical nature.

It had long been observed that many metals on exposure to fire lost their peculiar lustre, and it was also known that by the prolonged action of heat they were ultimately converted into *calces* or earthy powders often possessing characteristic colours. The fact that the calx weighs more than the metal from which it was derived was known to Geber, and was well understood by the alchemists of the 16th century. Cardan (1506-1576) in noticing the increase of weight which accompanies the calcination of lead, says that it is due to a gas (*flatus*) which feeds flame and rekindles a body presenting an ignited point; and Cæsalpinus in the *De Metallicis* (published at Nuremberg in 1602) also states that the '*crasse*' which forms on the surface of lead exposed to heated air contains an aerial substance which increases the weight of the metal. Rey of Perigord seems to have first clearly recognised that the augmentation in weight was due to the action of the air. '*Je responds et soutiens glorieusement que ce surcroit de poids vient de l'air qui dans le vase a été épaissi.*' Hooke in 1665 asserted that air contains a principle analogous to if not identical with that contained in nitre, and he seems to have believed that a certain portion only of the air is required to support combustion and respiration. The conception of the complex nature of the air was greatly strengthened by the observations of Mayow on respiration: his experiments are so precise and his facts so incontestable that, to quote Chevreul, one is surprised that the truth was not fully recognised until a century after his researches. Boyle also considerably extended our knowledge of the physical and chemical constitution of the air in the various treatises which he published between 1672 and 1692.

Two years after the sagacity of Rutherford had demonstrated the existence of nitrogen, Priestley obtained oxygen gas by heating the calx of mercury or red precipitate. The significance of this discovery in its relation to the constitution of the air and true nature of calcination was first clearly and irrefragably demonstrated by Lavoisier. By heating mercury in contact with a measured volume of air, he showed that about one-fifth of the volume of

the air is absorbed by the metal with the formation of 'red precipitate,' from which the gas can be recovered by heating to a still higher temperature, and that the remaining four-fifths had all the properties of the 'mephitic air,' or nitrogen, of Rutherford. This experiment not only demonstrated the compound nature of the air and the character of its constituents, but it also showed approximately the relative quantities in which these constituents were present. It was of course quickly recognised that the active properties of air depended upon oxygen, and it was reasonable to assume that the relative amount of this gas determined the quality of air; hence arose the art of eudiometry. Priestley, who discovered nitric oxide in 1772, had observed that this gas became red in contact with the air and that the ruddy gas, unlike nitric oxide, was readily soluble in water. When it was subsequently ascertained that the formation of the soluble red gas was due to the action of oxygen on the nitric oxide, the idea of basing a eudiometric method upon this reaction was suggested by Priestley. Careful experimenters were, however, unable to distinguish air which was reputed to be unhealthy from that which experience had proved to be beneficial and salubrious. Thus, in Priestley's hands, air from the country seemed no better than that obtained from the worst-ventilated workshops of Birmingham. Cavendish, after a critical examination of the method, made numerous analyses of air. 'During the last half of the year 1781,' he says, 'I tried the air of near sixty different days in order to find whether it was sensibly more phlogisticated at one time than another, but found no difference that I could be sure of, though the wind and weather on these days were very various, some of them being very fine and clear, others very wet, and others very foggy. . . . On the whole, there is great reason to think that the air was in reality not sensibly more dephlogisticated on any one of the sixty days on which I tried it than the rest.' Cavendish devised a scale of gradation applicable to all nitric oxide eudiometers, by means of which the late Dr. Wilson calculated that the mean of his results furnished the following numbers, expressing the centesimal composition of the air by volume:

Oxygen . . . 20.833

Nitrogen . . . 79.167

100.000

Cavendish concludes his account of these observations by pointing out the character of the information furnished by the eudiometer. Etymologically the name was without significance. 'In so far as the instrument takes cognisance of the impurity of the atmosphere, it betrays no difference between one specimen of air and another; so that, apparently, there are no degrees of goodness to be measured. . . . Thus it may be inferred that our sense of smelling can, in many cases, perceive infinitely smaller alterations in the purity of the air than can be perceived by the nitrous test' (Cavendish, 'Account of a New Eudiometer,' T. 1783).

These conclusions were confirmed by Humboldt and Gay-Lussac in their celebrated

memoir on the composition of the air, published in 1804. They employed the eudiometric method of Volta, *i.e.* explosion with hydrogen, and from an extensive series of analyses made on air collected in the most variable weather they concluded that 100 vols. of air contained 21 of oxygen and 79 of nitrogen.

The constant proportion of the two principal constituents of the atmosphere appeared now to be so well established that many chemists, after the recognition of the atomic theory, were inclined to think that air was a definite compound of oxygen and nitrogen. The two main constituents of the air are, however, not present in the simple ratio demanded by the law of Gay-Lussac. There is no evidence of chemical combination on mixing oxygen and nitrogen in the proportion in which these gases are present in air: the properties of the mixture are identical with those of air and are such as might be predicated to result from such a mixture. Moreover, oxygen and nitrogen can be isolated from air by mechanical means, or by taking advantage of the different intestinal movements of the gases. Graham separated the gases by atmolysis, and Bunsen demonstrated that the two gases were absorbed by solvents on which they exerted no chemical action in exact accordance with the law of partial pressures. Lastly the more accurate eudiometric processes of the last forty years have shown that the proportion of oxygen to nitrogen even in so-called normal air is not absolutely constant. This fact was first clearly demonstrated by Bunsen: in a series of analyses made during January and February 1846, he found that the percentage amount of oxygen varied from 20.97 to 20.84 by volume, *i.e.* a difference of 0.13 p.c., whereas the error of experiment never exceeded .03 p.c. Even wider variations were found by Regnault in the course of a long series of analyses made on air collected in different parts of the world. In more than 100 analyses of air taken at various times of the year in and about Paris the lowest quantity of oxygen found was 20.913 and the highest 20.999; an extreme difference of 0.086; the experimental error being 0.02 p.c. Air collected from different parts of Europe, from valleys and from the tops of mountains and during different seasons of the year, showed variations in the amount of oxygen from 20.903 to 21.0 p.c.

Angus Smith found similar differences in London air in the course of numerous analyses made during 1869; the percentage amount of oxygen varied between 20.857 and 20.95. That these variations are due to local or accidental causes in the case of a town is established by the circumstance that the air in the streets is almost invariably poorer in oxygen than the air of the parks and open spaces. As types of normal air, Angus Smith found the following means of numerous analyses of air in Scotland (1863-5):

	Oxygen
Seashore and the heath	20.999
Tops of hills	20.98
Not mountainous	20.978
Forests	20.97

In marshy places the oxygen sank as low as 20.922.

In Glasgow, in a series of 30 analyses the oxygen varied from 20.889 in the closer parts to 20.929 in the more open places. A. R. Leeds found that the air of New York showed variations from 20.821 to 21.029 p.c.; and lastly Jolly found that air in Munich freed from carbonic acid and aqueous vapour varied in weight as much as 9 mgm. per litre, this variation depending upon the direction of the wind. By eudiometric measurement he obtained variations from 20.53 to 21.01 p.c. Southerly winds as a rule showed a relatively low percentage of oxygen. According to E. W. Morley these deficiencies in the relative amount of oxygen are to be attributed to the down-rush of air poorer in oxygen from the higher regions of the atmosphere. It was conjectured by Dalton and Babinet that air in the upper strata of the atmosphere contained relatively less oxygen than that immediately above the earth.

From Regnault's observations it would seem that sea-air contains slightly less oxygen than land air. The mean of 17 samples collected in the Arctic seas was 20.91, the extremes being 20.94 and 20.85. The mean of all the samples collected at sea was 20.84; in a series of twenty only five showed amounts of 20.96 and upwards. On the other hand, the observations of Lewy indicate that sea-air differs but little in composition from land-air, but that in the tropics it experiences close to the sea a diurnal variation in the amount of oxygen and carbonic acid, due to the action of the sun's heat in disengaging these gases from the water. Subsequent experiments on the composition of air over the sea have not confirmed these observations so far as the carbonic acid is concerned (*vide infra*).

We have comparatively little information in regard to the relative quantities of the constituents of the air at great heights. Such experimental evidence as exists seems to indicate that air contains relatively less oxygen in the higher strata than near the surface of the earth.

Very little is known respecting the proportion of ozone in the atmosphere, or of the circumstances which influence its production. The ozonometric methods hitherto devised are incapable of affording accurate quantitative estimations. Air over marshes or in places infested by malaria contains little or no ozone. No ozone can be detected in towns or in inhabited houses.

Houzeau (*A. Ch.* [4] 27, 5) determines the relative amount of ozone in the air by exposing strips of red-litmus paper dipped to half their length in a 1 p.c. solution of potassium iodide. The paper in contact with ozone acquires a blue colour from the action of the liberated potash upon the red litmus. The iodised litmus paper is preferable to iodised starch paper (Schönbein's test-paper) which exhibits a blue coloration with any reagent which liberates iodine, *e.g.* nitrous acid, chlorine, &c. From observations made with iodised litmus paper Houzeau concludes that ozone exists in the air normally, but the intensity with which it acts at any given point of the atmosphere is very variable. Country air contains at most  $\frac{1}{100000}$  of its weight or  $\frac{1}{700000}$  of its volume of ozone.

The frequency of the ozone manifestations varies with the seasons, being greatest in spring, strong in summer, weaker in autumn, and weakest in winter. The maximum of ozone is found in May and June, and the minimum in December and January. In general ozone is more frequently observed on rainy days than in fine weather. Strong atmospheric disturbances, as thunder storms, gales, and hurricanes, are frequently accompanied by great manifestations of ozone. According to Houszeau atmospheric electricity appears to be the most active cause of the formation of atmospheric ozone.

The existence of *hydrogen peroxide* in air was first established by Meissner in 1863, but we have no knowledge of the proportion in which it is present. All information as to its relative distribution is obtained from determinations of its amount in rain water and snow. The proportion seems to vary, like that of ozone, with the seasons of the year and with the temperature of the air. It is not improbable that the amount of hydrogen peroxide in air is greater than that of ozone, and it is possible that many so-called ozone manifestations are in reality due to peroxide of hydrogen (v. Houszeau, *C. R.* 76, 491; Schönbein, *J. pr.* 106, 270; Meissner, *J.* 68, 181; Schöne, *B.* 12, 316; 13, 1503).

The amount of *aqueous vapour* in the air is subject to great variations. It depends principally upon the temperature, on the distance from the equator, and on the level of the sea; on the form in which the aqueous vapour is precipitated; on the connexion between such precipitations and the change of temperature; and on the direction and succession of winds. The air is rarely saturated with aqueous vapour. In our moist climate saturation is sometimes very nearly attained, but in some parts of Central Asia, Russia, and Africa, extraordinary degrees of dryness have been noticed. In these islands the most humid month is January, and the driest is May.

The existence of *carbonic acid* in the atmosphere was first inferred by Dr. Macbride of Dublin, in 1764, from the observation that quicklime after exposure to the air effervesced on treatment with an acid. From the ease with which determinations of its amount may be effected our knowledge of the distribution of atmospheric carbonic acid and of the causes which affect its proportion is probably more precise than in the case of any other constituent of the air. In fresh country air the amount is remarkably constant, and may be stated as about .034 p.c. In large towns and cities it is usually greater; thus Angus Smith, from numerous analyses made in London during November 1869, found as a mean .044 p.c.; in upwards of 70 analyses the proportion fell below .04 p.c. on only 5 occasions. In Glasgow, Smith found on an average .05 p.c. The amount will of course be affected by any circumstances which interfere with the rapid diffusion of the carbonic acid produced by respiration and the combustion of fuel: hence during fogs the proportion is very greatly increased, an amount as high as 0.1 p.c. having been occasionally noticed. Smith gives the following summary of results obtained in Manchester (*Air and Rain*, p. 52).

	Per cent.
In Manchester streets in usual weather	.0403
During fogs	.0679
Where the fields begin	.0369

In country air the amount of carbonic acid is invariably greater at night than during the day. This remarkable diurnal variation was first pointed out by Saussure (*P.* 19, 391), and has been fully confirmed by subsequent observers. Thus, as the mean of numerous analyses made at Clermont-Ferrand, Truchot (*C. R.* 77, 675) obtained during the day .0353, and during the night .0403 (v. also G. F. Armstrong, *Pr.* 1880, 343; and Muntz a. Aubin, *C. R.* 92, 1299). These differences are mainly due to the exhalation of carbonic acid from plants at night. In the air of towns, and in the absence of vegetation, no such diurnal variations can be detected.

The amount of carbonic acid in the air is not sensibly altered by rain: this indeed would follow from the law of partial pressure. Over the sea the amount of carbonic acid is about .03 p.c., and, contrary to the statement of Lewy, no diurnal variation in the amount can be perceived (Thorpe, *C. J.* [2] 5, 189). Schulze (*Landw. Versuchs.-St.* 14, 366) obtained similar results with sea air at Rostock: the mean of a large number of observations made from 1868 to 1871 was .0292 p.c. No definite change in the amount was observed at different seasons of the year or at different times of the day. Fog and also a fall of snow were often associated with an increase of carbon dioxide (v. also Pittbogen a. Hasselbarth, *C. C.* 1874, 694).

Very little is known concerning the distribution of carbonic acid in the higher strata of the atmosphere. According to Saussure and Schlägenter the amount of carbonic acid on the mountains is greater than on the plains: Truchot, however, found only .0203 on the top of the Puy-de-Dôme (1416 m.), and .0172 on the Peak of Nancy (1884 m.), as against .0313 at Clermont-Ferrand. Additional observations are required.

The existence of *nitric acid* in the air was first inferred by Priestley. The amount, however is so small that it can only be detected in rain-water. Nitroxy compounds are occasionally produced during thunder-storms, and it is said that the rain collected during a storm often contains notable quantities of nitrous and nitric acids. Boussingault found that a million parts of rain water contained 0.83 parts of nitric acid. Reichardt found in hailstones collected during a thunderstorm 0.526 parts per million.

According to Barral each hectare at Paris receives annually from the rain about 63.6 kilos of combined nitric acid. Bineau found that 1 litre of rain-water at Lyons contained in winter 0.3 mgm. nitric acid; in spring 1.0; in summer 2.0 mgm.; and in autumn 1.0 mgm. Bobierre found that a cubic metre of rain-water collected at Nantes in 1863 contained on an average 7.36 grams in the upper part, and 5.682 grams in the lower part, of the town (*C. R.* 1864, 755). Angus Smith (*Air and Rain*, p. 287) obtained the following results from a large number of observations on rain-water.

portion of micro-organisms in air. The method consists in aspirating air through wide-mouthed glass tubes, coated internally with gelatine-peptone, prepared according to Koch's method, which is afterwards kept at a temperature of 20°-26° for a few days, when the organisms which have been arrested—consisting of the various monads, bacilli, and micrococci, capable of development and growth in the nutrient gelatine—are recognised by the colonies to which they give rise. By means of this method Dr. Percy F. Frankland has made a number of estimations of the micro-organisms contained in the air of towns, and in the country, and in inhabited buildings. By simultaneously exposing small circular glass dishes partially filled with the nutrient gelatine to the action of the air, a rough estimate was obtained not only of the number of micro-organisms in a given volume of the air, but also of the number which fell during a given time on a definite horizontal area. As the mean of a series of observations made on the roof of the South Kensington Museum between Jan. and June 1886, it was found that there were 35 organisms in 10 litres of air, whilst 279 was the average number which fell in 1 sq. ft. in 1 minute. Similar experiments made near Reigate and in the vicinity of Norwich showed an average of 14 organisms in 10 litres of air, whilst 79 fell per sq. ft. per minute. Experiments made in Kensington Gardens, Hyde Park, and on Primrose Hill, gave an average of 24 organisms in 10 litres, and a deposition of 85 per sq. ft. per minute. At St. Paul's Cathedral, 56 organisms were found at the base, 29 in the Stone Gallery, and 11 in the Golden Gallery, in 10 litres of air. At Norwich Cathedral 18 at the base, 9 at a height of 180 ft., and 7 at 300 ft. In inhabited buildings great variations were observed; as a rule the number of micro-organisms was less than that found in the open air when the air of the room was undisturbed, but rose rapidly when the air was set in motion by draughts or by the presence of many people (P. F. Frankland, *Pr.* 40, 509).

Angus Smith has sought to base a system of chemical climatology on the examination of rain-water collected under different conditions and at various places. Rain falling through the air over the sea always contains common salt and sulphates, the latter in larger proportion to the chlorides than is found in sea-water. The sulphates increase inland: they seem to be a measure of the products of decomposition, the sulphuretted hydrogen which is evolved in the putrefaction of certain organic compounds being oxidised in the atmosphere. In large towns, the amount of the sulphates is greatly increased owing to the combustion of coal containing iron-pyrites. Indeed the rain water of large towns is frequently acid from the presence of free sulphuric acid. When rain contains 40 parts per million of free acid, vegetation is rapidly affected. The following analyses by Angus Smith will serve to show the general character of the rain-water (and therefore of the impurity of the atmosphere) in various parts of Great Britain. The results, which are the mean of many experiments, are expressed in parts per million of rain-water.

Although the atmosphere is subject to continual change from a multitude of causes, such as the respiration of animals and plants, the combustion of organic matter, various processes in the arts &c., still from its immense mass and uninterrupted motion such changes have only the very slightest effect on its composition. Let us very briefly consider the chief circumstances which tend to influence the proportion of its components.

Nitrogen is undoubtedly a primitive substance: no other body occurs in such large quantities as an element. This gas is probably the source of all nitrogenous bodies, in the formation of which it is continually abstracted from the air. A portion only of the nitrogen so abstracted finds its way back to the air as such: the most considerable compensating influence known to us is the nitrogen evolved by volcanoes.

By the respiration of animals and the oxidation of the spent portions of their tissue, by the respiration of plants at night-time, and by the combustion of fuel, large quantities of carbonic acid are being continually added to the atmosphere. Enormous quantities also are evolved from volcanoes and other subterranean sources. Poggendorff has indeed calculated that the amount so added is at least ten times as much as is derived from all other sources put together. Taking the weight of carbonic acid in the air as '06 per cent., it can be calculated from the area of the terrestrial oblate spheroid that the weight of the carbonic acid in the atmosphere is about 3,225,000 × 10 kilos (Le Conte, *P.M.* [5] 15, 46; v. also E. H. Cook, *P. M.* [5] 14, 387). At least 50,000 million kilos of carbonic acid are daily added to the air. The main compensating influence is of course the action of growing plants in sunshine; carbon dioxide is also removed directly and indirectly by zoophytes and by certain chemical actions such as the conversion of felspar into kaolin, &c. Sterry Hunt ('Chemical and Geological Relations of the Atmosphere,' *Am. S.* 1880) has calculated that a weight of carbonic acid equal to more than twenty-one times that of our present atmosphere would be absorbed in the production from orthoclase of a layer of kaolin extending over the earth's surface with a thickness of 500 metres, an amount representing

but a small proportion of the results of feldspathic decay in the sedimentary strata of the globe.

Dumas and Boussingault, in their well-known memoir on the *Composition of the Air* (A. Ch. [3] 8) made some interesting calculations on the duration of the supply of atmospheric oxygen. They found that, taking all the known sources of diminution, and assuming that the oxygen disengaged by plants compensates only for the causes of diminution at present unknown, then even in this exaggerated case three times the amount of oxygen thus abstracted would only amount in 100 years to about  $\frac{1}{1000}$  of the total quantity, an amount barely appreciable by our most exact eudiometric methods.—T. E. T.

**ATOMIC AND MOLECULAR WEIGHTS.**—Two theories regarding the ultimate constitution of matter have opposed each other from the beginnings of philosophy; one asserts that any mass of apparently homogeneous matter is really homogeneous; the other affirms that every portion of matter of sensible size is built up of a vast number of small particles which are not themselves capable of further sub-division. The earliest exponent of the second theory of whom we possess any definite record was the Greek philosopher Democritus, who flourished about 450 B.C. The doctrines of Democritus were developed by Epicurus, and the teachings of the Epicurean philosophy are preserved in the Latin poem of Lucretius (n.c. 99-55). These early atomists tried to assign to the atoms, of which they said matter is composed, only such properties as should suffice for their presentation in time and space. They taught that nothing exists save atoms and empty space; that the atoms or 'first-beginnings,' are of many different forms, and different weights, and the number of atoms of each form is infinite; that all change is only combination or separation of atoms; and that the atoms are in constant motion. To meet the objection that if a mass of matter is at rest the parts of it cannot be in motion, Lucretius uses the illustration of a flock of grazing sheep with skipping lambs; to one looking from a distance the flock appears as a white motionless patch on the green hillside, but a closer view shows that the parts of the flock are continually changing their positions. Every atom, Lucretius asserts, is indestructible, and its motion is indestructible likewise; if this were not so how could we account for the preservation of fixed types in nature? 'Roses always bear roses, and each animal reproduces its like, because the 'first beginnings' (or atoms) of which each is composed are the same and are never destroyed or worn out. 'First-beginnings are of solid singleness, and in no other way can they have been preserved through ages during infinite time past in order to reproduce things.'<sup>1</sup> Here we see how clearly the early atomists recognised that every event in nature occurs in accordance with strict laws. Nothing happens by chance, was a fundamental doctrine of these philosophers. 'I . . . teach . . . by what law all things are made, what necessity there is then for them to continue in that law, and how impotent they are to annul

the binding statutes of time.'<sup>1</sup> The way to gain a knowledge of the laws of nature, Lucretius teaches, is to examine natural events. (See for instance the analysis of the effects of the thunderbolt in Book vi. 323-398.) The differences between a hard body such as iron, and a soft body such as air, depend, according to Lucretius, on the motions of the atoms of the two bodies; in the hard body the atoms move to and fro within very small distances, in the soft body they move freely and rebound from each other only at comparatively long intervals. 'Bodies are partly first-beginnings of things, partly those which are formed by a union of first beginnings.'<sup>2</sup> The latter are produced by the atoms grouping themselves in *concilio*; this term seems to mean something very like our expression in *combination*. The properties of the body formed by the grouping together of atoms need not resemble the properties of the atoms themselves (see, for instance, Book I. 915-920). Not only must the atoms enter into *concilium* with each other in order that any kind of matter may be produced, but the properties of the matter thus formed depend on the mutual relations of the atoms; 'it matters much with what others' and in what positions the same first-beginnings of things are held in union, and what motions they do mutually impart and receive.'<sup>3</sup>

Although this theory was so nearly complete, yet, as taught by Lucretius, it had few of what we now regard as the essential features of a good scientific theory; it was not stated in terms which permitted of numerical applications to actual phenomena. Few or no exact applications of the theory could be made to natural phenomena. It was scarcely able to predict events in nature except in a wide and loose way. It savoured too much of a dogma. It was rather a speculation as to what might be the cause of natural occurrences, than an attempt to determine what these causes really were.

The teachings of the Epicurean philosophers were opposed by those of the school of Aristotle. The Aristotelians magnified the names of things and made them as real or even more real than the things themselves; they identified 'modes of predication with modes of existence' (Lange). Matter occupied a foremost position in the Epicurean scheme of the universe, but by the followers of Aristotle it was regarded only as the 'potentiality of becoming anything or everything.' Aristotelianism prevailed in the middle ages and atomism fell more and more into disrepute.

But in 1592, Gassendi, Canon and Provost at Digne in Provence, revived the atomic theory of the Greek philosophers, and attempted to found on it an interpretation of natural events. The influence of Gassendi was continued through Newton and Boyle; the former of whom, as we know, demonstrated that not only do masses of matter attract each other, but that every particle of each mass attracts every particle of the other mass with a force varying directly as the masses of the particles and inversely as the square of the distance between the particles. As Newton accepted the atomic conception of the structure of matter, his demonstration of the action of the force of gravitation gave a new

<sup>1</sup> Lucretius, *De Rerum Natura*, I. 548-550 (Munro's translation).

<sup>2</sup> Id. V. 75-58.

<sup>4</sup> Id. II. 1007-9.

point of departure for the theory of atoms. From this time a science of atomic physics became possible. But the difficulty was, and still is, to form a clear mental picture of the mechanism of the action of the force of gravitation in terms of the atomic conception of matter. Newton gave the mathematical construction, and clearly separated this from the physical explanation which belonged to the region of conjecture.

Not much was done, after Newton, to advance the application of the atomic theory until the early years of the present century, when Dalton made a serious attempt to determine the conditions under which the atoms of elementary bodies unite to form the atoms of compound bodies.

The great advance made by Dalton consisted in his asserting the possibility of finding the relative weights of the atoms of all kinds of matter, and in his demonstration of the method whereby these relative weights could be determined.

Many analyses of chemical compounds had been made before the time of Dalton; the results were usually stated in percentages, and they seemed to have but few mutual relations. Richter (1791-1802) had shown that a definite mass of each acid combines with a specified mass of a given base; he had arranged several acids and bases in order of neutralisation. Fischer, in 1803, published a table of chemical equivalents which expressed the quantities of bases which were of equal value as regarded power of neutralising a constant quantity of a specified acid. Lavoisier, Cavendish, and others, had to some extent grasped the conception of the elements combining in definite proportions. They had never doubted that every chemical substance was of definite composition, and that it would be possible by careful analyses of many compounds to find the laws of elementary combinations. Proust had analysed several pairs of oxides of the same metal; from some of his numbers the law of combining weights might have been deduced, had he stated his results so as to show the quantities of oxygen in combination with a fixed quantity of metal.

Dalton analysed two compounds of carbon and hydrogen, and found that in one there was twice as much hydrogen as in the other, combined with the same quantity of carbon. He found similar regularities in the quantities of oxygen which combined with a specified quantity of carbon, in the quantities of oxygen which combined with a specified quantity of nitrogen, &c. Meanwhile he had been thinking much regarding the ultimate particles of bodies; he had pictured to himself a quantity of gaseous matter as resembling a heap of small shot, as built up of little definite parts or atoms.\* He saw how the facts of chemical combination he had been studying would help him to find the relative weights of these small particles. Dalton's genius recognised the unity which bound together so many diverse physical and chemical facts. He at once stated clearly the quantitative laws of chemical combination and referred these laws to one underlying conception, the conception namely of the atom. 'In all chemical investigations it has justly been considered an important object to ascertain the relative weights of the simples which constitute a compound. But unfortunately the inquiry has terminated here; whereas

from the relative weights in the mass, the relative weights of the ultimate particles or atoms of the bodies might have been inferred, from which their number and weights in various other compounds would appear, in order to assist and to guide future investigation, and to correct their results. Now it is one great object of this work to show the importance and advantage of ascertaining the relative weights of the ultimate particles both of simple and compound bodies, the number of simple elementary particles which constitute one compound particle, and the number of less compound particles which enter into the formation of one more compound particle.'

That he might determine the relative weight of the 'ultimate particle' of an element it was necessary for Dalton to have some means of fixing the number of particles of that element in one 'ultimate particle' of several of its compounds. Thus, masses of hydrogen and oxygen combine in the ratio of 1 to 8; now, if we assume that the ultimate particle, or atom, of water is 9 times heavier than the atom of hydrogen, the most probable conclusion is that one atom of water is formed by the union of one atom of hydrogen, the mass of which is taken as unity, with one atom of oxygen, the mass of which is 8 times that of the hydrogen atom; but if we choose to assume that the atom of water is 16 times heavier than that of hydrogen, then the experimental results—1 of hydrogen combines with 8 of oxygen, by weight—are most readily interpreted by saying that one atom of water is formed by the union of 2 atoms of hydrogen, weighing 2, with one atom of oxygen, weighing 16. We cannot then determine how many times the atom of oxygen is heavier than that of hydrogen unless we have previously determined how many times the atom of the compound formed by the union of hydrogen and oxygen, that is the atom of water, is heavier than the atom of hydrogen.

Dalton framed certain empirical rules regarding the composition of the atoms of compounds formed by the union of two elements. His principal rules were these: 'If there are two bodies, A and B, which are disposed to combine, the following is the order in which combination may take place, beginning with the most simple, namely:

- 1 atom of A + 1 atom of B = 1 atom of C, binary;
- 1 atom of A + 2 atoms of B = 1 " D, ternary;
- 2 atoms of A + 1 atom of B = 1 " E, ternary;
- 1 atom of A + 3 atoms of B = 1 " F, quaternary;
- 3 atoms of A + 1 atom of B = 1 " G, quaternary;
- &c. &c.

'1st. When only one combination of two bodies [elements] can be obtained, it must be presumed to be a *binary* one, unless some cause appears to the contrary.

'2nd. When two combinations are observed they must be presumed to be a *binary* and a *ternary*.

'3rd. When three combinations are obtained, we may expect one to be a *binary*, and the other two *ternary*.

'4th. When four combinations are observed, we should expect one *binary*, two *ternary*, and one *quaternary*, &c. &c.'

\* From the application of these rules to the

\* Dalton, *A New System of Chemical Philosophy* (1808).

chemical facts already well ascertained, we deduce the following conclusions: 1st. That water is a binary compound of hydrogen and oxygen, and the relative weights of the two elementary atoms are as 1:7 nearly [more correctly 1:8]. 2nd. That ammonia is a binary compound of hydrogen and azote, and that the relative weights of the two atoms are as 1:5 nearly [more correctly 1:4.66]. . . . In all these cases the weights are expressed in atoms of hydrogen, each of which is denoted by unity.<sup>1</sup> But even if these rules were admitted, it was not always possible to fix the relative weight of an elementary atom; thus, two compounds of carbon and oxygen were known to Dalton, containing, according to his analyses, 2.7 parts by weight of carbon combined with (i) 7 and (ii) 3.5 parts by weight of oxygen; hence, by rule 2, the first of these is a compound of one atom carbon with one atom oxygen, and hence the atomic weight of carbon is 2.7, and the second is a compound of 2 atoms carbon ( $=5.4$ ) with 1 atom oxygen ( $=3.5 \times 2$ ). But the results of analyses might also be stated thus: (i) 5.4 carbon + 14 oxygen, (ii) 5.4 carbon + 7 oxygen; and the conclusion might be drawn that the first is a compound of 1 atom carbon (5.4) with 2 atoms oxygen ( $7 \times 2$ ), and the second is a compound of 1 atom carbon (5.4) with one atom oxygen (7). Both ways of stating the results of experiments would be in keeping with Dalton's rules, but the first would lead to the number 2.7, and the second to the number 5.4, as representing the relative weight of the atom of carbon. Another objection to the Daltonian rules of atomic syntheses was that, although to-day we may know of but one compound of two specified elements, to-morrow we may know of several compounds of these elements.

Berzelius continued the work which Dalton had begun; his aim was to discover the laws of atomic combinations. Why does a specified element by combining with oxygen produce only two or perhaps three different oxides? Why do not the elementary atoms combine in a great many different ratios? What are the limiting forms of the compound atoms produced by the union of any specified elementary atoms? Berzelius busied himself with such questions as these. And that he might find some solutions to such questions, Berzelius was obliged to frame empirical rules, as Dalton had done before him.

The following may be taken as an example of the Berzelian rules. If an element forms two oxides with twice as much oxygen by weight in one as in the other, relatively to a fixed mass of the element, the atom of that compound which contains the smaller mass of oxygen is to be regarded as composed of one atom of oxygen and one atom of the specified element, and the atom of the other compound is to be regarded as composed of two atoms of oxygen and one atom of the specified element; but if the masses of oxygen in the two oxides are in the ratio 2:3 relatively to a specified mass of the other element, then the atom of the compound with less oxygen is to be regarded, as before, as composed of one atom of oxygen and one atom of the specified element, but the

atom of the compound with more oxygen is to be regarded as composed of three atoms of oxygen and two atoms of the other element.

But such rules were only empirical, and, however satisfactory might be the particular results obtained by their application, it was impossible to rest contented until some general principle had been attained which should admit of universal application. In the course of his inquiries regarding the syntheses of atoms, Berzelius performed a vast number of very careful analyses, the results of which firmly established the quantitative laws of chemical combination. These laws (*v. COMBINATION, CHEMICAL, LAWS OF*) assert:—(1) that the masses of the constituents of every homogeneous kind of matter stand in an unalterable proportion to one another, and also to the mass of the compound they produce—the mass of the compound being always equal to the sum of the masses of the constituents; (2) that when two elements combine to form more than one compound, the masses of one of the elements which combine with a constant mass of the other element bear a simple relation to each other; and (3) that the masses of different elements which combine with one and the same mass of another element are also the masses of these different elements which combine with each other, or they stand in a simple relation to those masses. Those laws may all be expressed in the statement that the elements combine only in the ratios of their combining weights, or, in simple multiples of these ratios. By the combining weight of an element is here meant the smallest mass of that element which is found to combine with one part by weight of hydrogen or with 8 parts by weight of oxygen.

As Berzelius was pursuing his investigations into the gravimetric composition of compounds, Gay-Lussac was making experiments on the volumetric composition of gaseous compounds. In 1809 this naturalist was able to prove (1) that the volumes of the gaseous elements which combine to form a gaseous compound stand in an unalterable proportion to each other; (2) that when two gaseous elements combine to form more than one gaseous compound, the volumes of one of the elements which combine with a constant volume of the other element bear a simple relation to each other; and (3) that the volumes of different gaseous elements which combine with one and the same volume of another gaseous element are also the volumes of these different elements which combine with each other, or they stand in a simple relation to those volumes. These laws may all be expressed by saying that the gaseous elements combine only in the ratios of their combining volumes, or in simple multiples of these ratios. By the combining volume of a gaseous element is here meant the smallest volume of that element which is found to combine with one unit volume of hydrogen, and a unit volume of hydrogen is defined to be the volume, at normal temperature and pressure, occupied by one unit mass of this element.

Gay-Lussac argued that the ratios of the masses of the combining volumes of gaseous elements are also the ratios of the masses of the atoms of these elements; and the conclusion

<sup>1</sup> Dalton, *lc.*

was drawn that equal volumes of gaseous bodies, measured at the same temperature and pressure, contain equal numbers of atoms. This conclusion, if admitted, seems to put into our hands a means for finding the relative masses of the atoms of many compounds and hence of many elements. But the application leads to unlooked-for results. Consider the case of hydrogen and oxygen: experiment shows that two volumes of hydrogen—weighing two—combine with one volume of oxygen—weighing 16—and produce two volumes of water-gas—weighing 18; hence, if equal volumes of gases contain equal numbers of atoms, two atoms of hydrogen—weighing two—combine with one atom of oxygen—weighing 16—and the product is two atoms of water-gas—each weighing 9. But each of these atoms of water-gas contains atoms of hydrogen and oxygen; now, the atom of oxygen has been shown to weigh 16 times as much as the atom of hydrogen; hence the atom of water-gas contains half an atom of oxygen. Again, consider the case of hydrogen and chlorine: experiment shows that one volume of hydrogen—weighing one—combines with one volume of chlorine—weighing 35.5—and that the product is two volumes of hydrochloric acid weighing 36.5; hence, if equal volumes of gases contain equal numbers of atoms, one atom of hydrogen has combined with one atom of chlorine to produce two atoms of hydrochloric acid. But as each atom of hydrochloric acid is composed of both hydrogen and chlorine, it follows that each atom of hydrochloric acid is formed by the union of half an atom of hydrogen and half an atom of chlorine. But these conclusions are at variance with the fundamental definition of the atom, which states that the atom is the smallest mass of a body that can exhibit the properties of that body.

The discovery that gaseous elements combine in fixed quantities by volume had done something to advance the study of atomic synthesis, but it had not removed the fundamental difficulty, the difficulty, namely, of finding some generally applicable principle by means of which the relative weights of the ultimate particles, or atoms, of compounds might be determined. This difficulty was overcome by Avogadro. In 1811 this Italian naturalist introduced into chemistry the conception of two orders of small particles—the *molecule*, and the *atom*. The molecule of an element or a compound, said Avogadro, is the smallest mass of it which exhibits the properties of that element or compound; the molecule of an element or a compound is formed by the union of smaller particles of matter which we shall call atoms; in the case of the molecule of an element the atoms are all of one kind, in the case of the molecule of a compound the atoms are of two, or more than two, different kinds. As the properties of the molecule of a compound are very different from the properties of the atoms which compose it, so it is probable that the properties of the molecule of an element are different from the properties of the atoms by the union of which the molecule is produced. A chemical action between two gases was conceived by Avogadro as being separable, in thought if not in actuality, into two stages; in

the first stage the molecules of the reacting gases are shattered, and in the second stage the parts of these molecules, that is the atoms, are rearranged to form the molecules of the new bodies.

Avogadro modified the generalisation made by Gay-Lussac, and re-stated it thus:—*'Equal volumes of gases, temperature and pressure being the same, contain equal numbers of molecules.'* The reactions between hydrogen and oxygen, and hydrogen and chlorine, which could not be explained by the generalisation of Gay-Lussac, are perfectly consistent with the generalisation of Avogadro. Two volumes of hydrogen combine with one volume of oxygen, and the product is two volumes of water-gas; that is, in terms of Avogadro's statement,  $2p$  molecules of hydrogen, each composed of  $x$  atoms, combine with  $p$  molecules of oxygen, each composed of  $x'$  atoms ( $x$  may or may not equal  $x'$ ), and the product is  $2p$  molecules of water-gas. One volume of hydrogen combines with one volume of chlorine to form two volumes of hydrochloric acid; that is, in terms of Avogadro's statement,  $p$  molecules of hydrogen, containing  $x$  atoms, combine with  $p$  molecules of chlorine, containing  $x'$  atoms ( $x$  may or may not equal  $x'$ ), to form  $2p$  molecules of hydrochloric acid.

Not only are these, and other, reactions, between gases explicable in terms of the generalisation of the Italian naturalist, but this statement gives us a means of determining the relative masses of the molecules of all gaseous bodies, and also of determining the minimum number of atoms in each of these molecules. That is to say, the generalisation of Avogadro gives us what we could not obtain from the rules of Dalton or Berzelius, or from the generalisation of Gay-Lussac. For it is evident that, if the number of molecules in equal volumes of two gases is the same, the masses of the two kinds of molecules must be in the same ratio as the densities of the two gases; and hence, if the density of one of the gases be taken as unity, the density of the other, in terms of this one, expresses the relative mass of a molecule of this other gas. Let the two gases be hydrogen and oxygen; experiment shows that a given volume of oxygen is sixteen times heavier than the same volume of hydrogen; hence, if equal volumes contain equal numbers of molecules, a molecule of oxygen is sixteen times heavier than a molecule of hydrogen. Let us call the mass of a molecule of hydrogen one, then, in order to find how many times greater than the mass of this molecule is the mass of the molecule of any gas, we have only to determine the density of the specified gas in terms of hydrogen as unity; the number expressing the density of the gas expresses also the relative mass of the molecule of the gas. But, further, the generalisation of Avogadro puts into our hands a means whereby the minimum number of atoms in a gaseous molecule may be determined, and hence a means whereby the maximum relative values to be assigned to the masses of atoms may be determined. Consider the mutual action of hydrogen and chlorine, hydrogen and bromine, nitrogen and hydrogen, and oxygen and hydrogen. Having regard only to the volumes of the reacting gaseous elements and the volumes of the

gaseous compounds produced, the actions in question may be stated thus:—

(i.) One volume of hydrogen combines with one volume of chlorine to produce two volumes of hydrochloric acid; (ii.) One volume of hydrogen combines with one volume of bromine-gas to produce two volumes of hydrobromic acid; (iii.) one volume of nitrogen combines with three volumes of hydrogen to produce two volumes of ammonia; (iv.) one volume of oxygen combines with two volumes of hydrogen to produce two volumes of water-gas.

Now, as equal volumes contain equal numbers of molecules, these statements may be put as follows:—

(i.)  $p$  molecules of hydrogen combine with  $p$  molecules of chlorine, and the product is  $2p$  molecules of hydrochloric acid; (ii.)  $p$  molecules of hydrogen combine with  $p$  molecules of bromine gas, and the product is  $2p$  molecules of hydrobromic acid; (iii.)  $p$  molecules of nitrogen combine with  $3p$  molecules of hydrogen, and the product is  $2p$  molecules of ammonia; (iv.)  $p$  molecules of oxygen combine with  $2p$  molecules of hydrogen, and the product is  $2p$  molecules of water-gas.

Therefore in (i.) one molecule of hydrogen has produced, by union with chlorine, two molecules of hydrochloric acid, both of which are composed of hydrogen and chlorine; in (ii.) one molecule of hydrogen has produced, by union with bromine, two molecules of hydrobromic acid, both of which are composed of hydrogen and bromine; in (iii.) one molecule of nitrogen has produced, by union with hydrogen, two molecules of ammonia, both of which are composed of nitrogen and hydrogen; and in (iv.) one molecule of oxygen has produced, by union with hydrogen, two molecules of water-gas, both of which are composed of oxygen and hydrogen. In other words, in reactions (i.) and (ii.) every molecule of hydrogen has separated into at least two parts; in reaction (iii.) every molecule of nitrogen has separated into at least two parts; and in reaction (iv.) every molecule of oxygen has separated into at least two parts.

These parts of molecules are called atoms.

If we assume the truth of Avogadro's generalisation, then the foregoing reactions are most simply interpreted by saying that the molecules of hydrogen, nitrogen, and oxygen, are each built up or composed of two atoms. As hydrogen is the standard element to which the atomic and molecular weights of all other bodies are referred, we say that the *atomic weight of hydrogen is one*, and, because of such reactions as those just stated, that the *molecular weight of hydrogen is two*. But if the molecular weight of hydrogen is two, the molecular weight of oxygen must be 32, the molecular weight of nitrogen must be 28, the molecular weight of hydrochloric acid must be 36.5, the molecular weight of hydrobromic acid must be 81, the molecular weight of ammonia must be 34, and the molecular weight of water-gas must be 18; because oxygen is 16 times heavier than an equal volume of hydrogen, nitrogen is 14 times, hydrochloric acid is 18.25 times, hydrobromic acid is 40.5 times, ammonia is 17 times, and water-gas is 9 times, heavier than an equal volume of hydrogen.

By such reactions and such modes of reason-

ing as these, we arrive at the following practical definition of the molecular weight of a gaseous element or compound:—*The molecular weight of a gaseous element or compound is a number which expresses how many times greater than two unit masses of hydrogen is the mass of the specified element or compound which occupies (under the same conditions of temperature and pressure) the same volume as is occupied by these two unit masses of hydrogen.*

Determinations of the sp. gravs. of gases are subject to several sources of error. But the values to be assigned to the combining weights of the elements, that is, the masses of the elements which combine with one part by weight of hydrogen or 8 parts by weight of oxygen, can be determined with great accuracy. Now, it is evident that the molecular weight of an element must be equal to the combining weight of this element or to a simple multiple of this number, and that the molecular weight of a compound must be equal to the sum, or to a multiple of the sum, of the combining weights of its constituent elements; hence the data which are required for an accurate determination of the molecular weight of an element are (i.) an exact determination of the combining weight of the element, and (ii.) a measurement of the relative density of the element in the state of gas; similarly the data which are required for an accurate determination of the molecular weight of a compound are (i.) exact determinations of the combining weights of the constituent elements, and (ii.) a measurement of the relative density of the compound in the state of gas. Thus, 35.37 parts by weight of chlorine combine with 1 part by weight of hydrogen, therefore the molecular weight of chlorine is  $35.37$ ; but a given volume of chlorine is 35.5 times heavier than an equal volume of hydrogen, therefore the molecular weight of chlorine is approximately  $35.5 \times 2 = 71$ ; now,  $2 \times 35.37 = 70.74$ ; hence the molecular weight of gaseous chlorine is 70.74. Again, phosphorus hydride is composed of masses of phosphorus and hydrogen united in the ratio 10.32 to 1, therefore the molecular weight of this compound is  $11.32$ ; but this compound in the state of gas is 17 times heavier than hydrogen, therefore its molecular weight is approximately equal to  $17 \times 2 = 34$ ; now,  $3 \times 11.32 = 33.96$ ; hence the molecular weight of gaseous phosphorus hydride is 33.96.

Having thus arrived, by the help of Avogadro's generalisation, at a definition of molecular weight, and having determined that the molecules of hydrogen, nitrogen, and oxygen, and of some other elements, are very probably composed each of two parts or atoms, we proceed to find an 'exact meaning for the term atom. If the atom is assumed to be the ultimate portion of any homogeneous kind of matter of which cognisance is to be taken in chemistry, then it is evident that a molecule of a compound gas, formed by the union of (say) three elements, A, B, and C, must be formed by the union of at least one atom of the element A, one atom of the element B, and one atom of the element C. In general terms, no molecule of a compound gas can be formed by the combination of less than a single atom of each of the elements by the union of which the compound in question is

produced. This is equivalent to saying, the atom of an element is the smallest mass of that element which combines with other atoms to produce a molecule.

We cannot as yet determine the absolute mass of the atom of any element, but we have agreed to call the mass of an atom of hydrogen unity, and to represent the masses of the atoms of other elements in terms of the atom of hydrogen; hence we arrive at the practical definition of the maximum atomic weight of an element as follows:—

*The maximum atomic weight of an element is a number which expresses how many times greater is the smallest mass of that element which combines with other elements to form a compound gaseous molecule, than the smallest mass of hydrogen which combines with other elements to*

*14.485 times heavier than the same volume of hydrogen at the same temperature and pressure; therefore the relative density of any gas referred to air as unity multiplied by 14.485  $\times$  2 (= 28.87) gives the relative density of that gas referred to hydrogen as twice unity, that is, gives (approximately) the molecular weight of the gas. Let it now be required to determine the atomic weight of oxygen; the definition of atomic weight tells that the molecular weights of several gaseous compounds containing oxygen must be analysed and the results in each case stated in parts by weight of each element per molecule of the compound, and that the smallest mass of oxygen thus found in any molecule is to be taken as the atomic weight of oxygen. Here are some of the data which have been thus accumulated:—*

*Data for determining the atomic weight of Oxygen.*

Gaseous compound	Sp. Gr. air=1	Sp. Gr. $\times$ 28.87; i.e. approximate molecular weight	Molecular weight	Analysis, stated in parts by wt. per molecule
Carbon dioxide .	1.53	44.2	43.89	31.92 oxygen + 11.97 carbon
Sulphur dioxide .	2.25	64.9	63.90	31.92 " + 31.98 sulphur
Sulphur trioxide .	2.9	83.7	79.86	47.88 " + 31.98 "

*produce a compound gaseous molecule, such smallest mass of hydrogen being taken as unity.*

The term, and the conception underlying the term, molecule, are applied to compounds and elements alike; the term, and the conception

Were these the only known gaseous compounds containing oxygen we should conclude that the atomic weight of oxygen is 31.92, that of hydrogen being unity. But the following numbers show that this conclusion is incorrect:—

*Data for determining the atomic weight of Oxygen.*

Gaseous compound	Sp. Gr. air=1	Sp. Gr. $\times$ 28.87; i.e. approximate molecular weight	Molecular weight	Analysis, stated in parts by wt. per molecule
Carbon monoxide	.97	27.97	28.93	15.96 oxygen + 11.97 carbon
Water . . .	.63	18.2	17.96	15.96 " + 2 hydrogen
Nitric oxide . .	1.04	30.0	29.97	15.96 " + 14.01 nitrogen

underlying the term, atom, are applied in strictness to elements only.

The foregoing definitions of atomic weight and molecular weight are practical, because they indicate the nature of the data which must be obtained before the atomic or molecular weight of a gaseous body can be found. Suppose it is required to find the molecular weight of oxygen; the mass of this element which combines with unit mass of hydrogen must be accurately measured; and the relative density of oxygen gas must be determined, the standard of reference being hydrogen taken as twice unity. Now, the relative densities of gases are determined by experiments in terms of air taken as unity; but a specified volume of air is

These numbers show that at least three compounds exist the gaseous molecule of each of which contains 15.96 parts by weight of oxygen; hence, as no molecule is known containing less than this mass of oxygen, 15.96 is taken as the atomic weight of oxygen. Before, then, the atomic weight of an element can be determined with a fair degree of probability a number of gaseous compounds of the element must be analysed; if only a few gaseous compounds of a specified element are known it is probable that the value deduced, from analyses of these compounds, for the atomic weight of the element, is too large; it certainly cannot be too small. Thus, let us consider the data for finding the atomic weight of aluminium:—

*Data for determining the atomic weight of Aluminium.*

Gaseous compound	Sp. Gr. air=1	Sp. Gr. $\times$ 28.87; i.e. approximate molecular weight	Molecular weight	Analysis, stated in parts by wt. per molecule
Aluminium chloride	9.35	270.0	266.26	54.04 aluminium + 212.22 chlorine
" bromide	18.6	537.5	532.54	54.04 " + 478.5 bromine
" iodide	27.0	780.0	813.22	54.04 " + 759.18 iodine

\* When no temp. is given the determinations were made somewhere between 0° and 100°, the numbers in these cases may be regarded as approximately representing the mean specific heats for the temperature-interval 40°-60°.

<sup>1</sup> The number for beryllium is that calculated by Humpidge from a series of determinations, at temperatures varying from 100° to 450°, made with a specimen of beryllium containing 99.2 per cent. of the metal. See further, p. 343.

<sup>2</sup> Spec. heats of boron, carbon, and silicon are discussed on p. 343-4.

<sup>3</sup> The higher temperature (+10°) is not given in Regnault's paper, but judging from the context it appears to be approximately correct.

<sup>4</sup> This number for chromium is probably too low; see Kopp, *A. Suppl.* 3, 77 (note).

<sup>5</sup> The specimen of manganese employed contained a little silicon.

<sup>6</sup> Spec. heat of molten gallium between 109° and 119° = .0802 (Berthelot; *Bl.* [2] 31, 229).

<sup>7</sup> Spec. heat of amorphous selenium determined at high temperatures is abnormal, because of the large quantity of heat absorbed before fusion.

<sup>8</sup> Spec. heat of zirconium calculated by Mixer and Dana from determinations made with a sample containing known quantities of aluminium.

<sup>9</sup> The specimen of molybdenum employed contained carbon.

<sup>10</sup> Spec. heat of gold is nearly constant from 0° to 600°: at 900° Sp. ht. = .0345, and at 1000° = .0352 (Vielle, *C. R.* 69, 702).

<sup>11</sup> Spec. heat of liquid mercuric at 55° = 0.033 (Regnault).

<sup>12</sup> The specimen of thallium employed contained a little oxide.

The numbers marked with † are probably too large. See Weber's papers referred to below.

The names of the various observers are abbreviated in the table:—

As no other gaseous compounds of aluminium, except these three, have been prepared in a state of purity and analysed, we conclude that the atomic weight of this metal is not greater than 54.04; but as only three gaseous compounds of aluminium are known, it is not unlikely that the true value to be assigned to the atomic weight of this element is  $\frac{54.04}{3}$  or  $\frac{54.04}{2}$  or  $\frac{54.04}{4}$ , &c. The greater the number of compounds of a given element which have been gasified and analysed, the greater is the probability that the value thence obtained for the atomic weight of the element represents the true value of this constant.

Avogadro's generalisation—equal volumes of gases contain equal number of molecules—places in the hands of chemists an instrument whereby they may determine the relative weights of the molecules of all gaseous or gasifiable compounds and elements, and the maximum values to be assigned to the atomic weights of all elements which form gaseous or gasifiable compounds. But at present the densities of only 14 elements have been determined in the gaseous state, and gaseous compounds of only 42 different elements have been prepared and analysed. Hence the application of the method introduced by Avogadro is limited. There are two other methods of general applicability for determining the values to be assigned to the atomic weights of elements; let us consider these methods briefly.

In 1819 a paper was published by two French naturalists, Dulong and Petit, on the specific heats of 13 solid elements, viz., copper, gold, iron, lead, nickel, platinum, sulphur, tin, zinc, bismuth, cobalt, silver, and tellurium (*A. Ch.* 10, 395).

The products obtained by multiplying the generally accepted atomic weights of the nine elements from copper to zinc in this list by the specific heats of these elements, and sub-multiples of the generally accepted atomic weights of the remaining four elements by the specific heats of these elements, had all nearly the same value. Generalising from these results, Dulong and Petit concluded that 'the atoms of all the simple bodies have exactly the same capacity for heat.' This generalisation has, on the whole, been borne out by subsequent research.

The table on p. 342 contains most of the well-established data regarding the specific heats of solid elements in so far as direct determinations are concerned.

The values to be assigned to the specific heats of beryllium, boron, carbon, and silicon, have been the subject of many experiments and of much discussion: Nilson and Pettersson (*B.* 13, 1451; v. also *C. N.* 42, 297) made a series of determinations with a specimen of metallic beryllium containing about 5 per. cent. of beryllium and iron oxides. The following were the most important results:—

<i>Specific Heat of Beryllium (Nilson &amp; Pettersson).</i>				
Temp. interval	Spec. ht.	Spec. ht. $\times 9.1$	Spec. ht. $\times 13.65$	
0°–40	.3973	3.6	5.4	
0–100	.4246	3.86	5.8	
0–214	.475	4.26	6.4	
0–300	.5055	4.6	6.9	

Nilson and Pettersson concluded from these numbers that the atomic weight of beryllium is

13.65; but L. Meyer (*B.* 18, 1780) showed that the true values for the spec. heat of this metal at various temperatures, as calculated from the data summarised in the preceding table, are as follows:—

*Specific Heat of Beryllium (Meyer).*

Temp.	Spec. ht.	Increase in spec. ht. for 1°	Sp. ht. $\times 9.1$	Sp. ht. $\times 13.65$
20.2°	.3973	.00101	3.62	5.43
73.2	.4481	.00085	4.08	6.12
157	.5193	.00063	4.73	7.10
256.8	.5819		5.29	8.94

These numbers show that the specific heat of beryllium increases as temperature increases, but that the rate of this increase is considerably less for the interval 157° to 256° than for that of 20° to 157°. Humpidge (*Pr.* 39, 1), working with a specimen of beryllium prepared with great care and containing 99.2 per cent. of the metal and .7 per cent. of beryllium oxide, obtained the following results:—

*Specific Heat of Beryllium (Humpidge).*

Temp.	Spec. heat	Spec. ht. $\times 9.1$
100°	.4702	4.28
200	.5420	4.93
400	.6172	5.61
500	.6206	5.65

The value approximates to a constant between 450° and 500°. There can now be little doubt that the specific heat of beryllium is considerably larger at high than at low temperatures, that this value is nearly constant at about 500° and upwards, and that at these temperatures beryllium is not an exception to the law of Dulong and Petit. (For more details v. BERYLLIUM.)

Very varying values had been obtained for the specific heats of the three elements, boron, carbon, and silicon, before the researches of Weber. The following table summarises the chief results:—

*Specific Heats of Boron, Carbon, and Silicon (Weber's numbers not included).*

Weber, about 1872, made a careful series of determinations of the specific heats of these three elements (*P. M.* [4] 49, 161 and 276); his

more important results are presented in the following table:—

*Specific Heats of Boron, Carbon, and Silicon (Weber).*

	Temp.	Spec. heat.	Sp. ht. $\times$ at. wt.

These numbers show that the specific heats of boron, carbon, and silicon increase as temperature increases, but that, in each case, the value of this increase for a given temperature-interval is considerably less at high than at low temperatures. The observed variation in the rate of increase of the specific heat of crystallised boron<sup>1</sup> is nearly identical with the observed variation in the rate of increase of the specific heat of crystallised carbon for equal intervals of temperature up to 230-250°; if it is assumed that this identity remains at higher temperatures, then the specific heat of crystallised boron<sup>1</sup> may be calculated, from the observations made with crystallised carbon, at temperatures up to about 1000°. The value thus calculated for the specific heat of boron at 1000° is '56. The specific heat of crystalline silicon attains an almost constant value at about 230°. (For more details *v. Boron, Carbon, Silicon.*)

Looking at the determinations of the specific heats of solid elements as a whole, it appears clear that the specific heat of any element varies with the temperature, and that the relation between the variation of specific heat and that of temperature differs for each element; and, moreover, that the value of the specific heat of an element depends to some extent on the physical condition of the element. But there seems certainly to be an interval of temperature for which the specific heat of an element attains a constant, or nearly constant, value; this temperature-interval varies for each element, especially for the non-metallic elements with small atomic weights; for many elements it may be approximately taken as 0° to 100°(C.).

<sup>1</sup> There is, however, considerable doubt whether the material used by Weber was pure boron.

For this interval of temperature only can any element be said to obey the law of Dulong and Petit.

This law may now be stated in a practical form thus:—*The atomic heat, i.e. the product of specific heat, at the temperature-interval for which sp. ht. is nearly constant, into atomic weight, of all solid elements is nearly a constant, the mean value of which is 6·4.* If this is granted it follows that the atomic weight of any solid element is approximately equal to the quotient

$\frac{6·4}{\text{spec. heat}}$ ; provided that the specific heat of the element has been determined for a considerable range of temperature, and, if the specific heat has been found to vary considerably with variations of temperature, that the determinations have been continued until a constant, or a nearly constant, value has been obtained.

Attempts have been made to determine the specific heats of several elements by an indirect method. The method is based on the generalisation,

$\frac{A \cdot C}{n} = \text{a constant (about 6·4)}$ ; where  $A$  = the

formula-weight of a solid compound,  $C$  = the specific heat of the compound, and  $n$  = the number of elementary atoms in the formula of the compound. This generalisation has been stated in various forms; the earliest appears to be that given by F. Neumann, in 1831: 'The amounts of chemically similar compounds expressed by their formulae possess equal specific heats' (*P.* 23, 1). The statement is sometimes put thus: 'the molecular heat of a solid compound is equal to the sum of the atomic heats of its constituent elements;' by 'molecular heat' is here meant the product of the specific heat of the compound into the mass expressed by its formula. The form given above,  $\frac{A \cdot C}{n} = a$

constant, is the outcome of investigations made principally by Garnier (*C. R.* 35, 278; 37, 130), and Cannizzaro (*Bl.* 1863. 171).

As an example of the application of this generalisation, to find a value for the specific heat of an element in the solid form, let us take Kopp's calculation of the specific heat of solid chlorine (*A. Suppl.* 3, 321). The data are these:—molecular heats (as defined) of metallic haloid salts:  $RCl = 12·8$ ,  $RBr = 13·9$ ,  $RI = 13·4$ ;  $RCl_2 = 18·5$ ,  $RI_2 = 19·4$ . In each case  $R$  represents one atom of a metal the atomic heat of which is 6·4. The atomic heat of solid bromine = atomic heat of solid iodine = 6·6 (approximately). Now, as the metallic chlorides, bromides, and iodides, examined are chemically similar, and as the 'molecular heats' of the similar salts are nearly the same, Kopp has concluded that the atomic heat of solid chlorine is approximately equal to 6·4. This conclusion is in keeping with the observed values; thus:  $RCl (12·8) - R(6·4) = 6·4$ ;  $RCl_2 (18·5) - R(6·4) = 12·1$ , and  $\frac{12·1}{2} = 6·05$ .

Further data are presented by the following 'molecular heats':  $KClO_3 = 24·8$ ,  $KAsO_3 = 25·3$ . The argument here is, that as these values are nearly the same, and as the difference in composition between the two compounds is represented by the exchange of  $Cl$  for  $As$ , it follows that the atomic heat of solid chlorine is approximately

equal to that of arsenic; but the atomic heat of arsenic, as determined by direct experiment, is 6.1, hence the atomic heat of solid chlorine is approximately equal to 6.1.

This indirect method often leads, as might be expected, to several values for the specific (or atomic) heat of an element. Thus, from determinations of the 'molecular heats' of various oxides and other salts containing metals the atomic heat of each of which has been directly determined to be approximately 6.4, the following values for the atomic heat of solid oxygen are arrived at:

From RO	4.6
" RO <sub>2</sub>	3.7
" R <sub>2</sub> O <sub>3</sub>	4.8
" KAsO <sub>4</sub>	4.2
" KClO <sub>4</sub>	3.5 (assuming at. ht. of Cl = 6)
" KMnO <sub>4</sub>	3.8

The mean of these values is 4.1.

The indirect method of finding the atomic heat of an element is undoubtedly useful, but no great stress can be laid on conclusions arrived at by this method only. It is certain that an erroneous conclusion regarding the value of the atomic weight of an element may be deduced from measurement of the specific heats of solid compounds of that element. For example, Donath determined the specific heat of uranosouranic oxide to be .0798 (*B.* 12, 742); assuming the specific heat of solid oxygen to be 0.25 ( $= \frac{4.1}{16}$ ), the specific heat of uranium was calculated to be .0497; now  $.0497 \times 120 = 5.96$ , therefore, as analyses of compounds had proved that the atomic weight of uranium is  $\approx 120$ , it was concluded by Donath that the atomic weight of uranium is 120. But pure metallic uranium was prepared shortly afterwards, and the specific heat of this metal was directly determined to be .028; now  $.028 \times 120 = 3.3$ , but  $.028 \times 240 = 6.6$ ; hence the atomic weight of uranium is much more probably 240 than 120. The larger value (240) has been confirmed by the preparation and analyses of two gaseous compounds of uranium (*v.* regarding this subject, Kopp, *B.* 19, 813).

The following statements fairly summarise the results of the determinations of the atomic heats of the elements:

I. *Solid elements, 45 in number, the specific heats of which have been directly determined, and the atomic heats of which are all approximately equal to 6.4:* Li, Na, Mg, Al, P, S, K, Ca, Ti, Mn, Fe, Co, Ni, Cu, Zn, As, Se, Br, Zr, Mo, Ru, Rh, Pd, Ag, Cd, In, Sn, Sb, Te, I, La, Ce, Di, W, Os, Ir, Pt, Au, Hg, Tl, Pb, Bi, Th, U... (Cr).

II. *Solid elements, 6 in number, the specific heats of which have been directly determined, and vary considerably with temperature, and the atomic heats of which appear to be approximately equal to 5.5:* Ga (? inaccurately determined), Be, B, C, Si, Ge.

III. *Solid elements, 5 in number, the specific heats of which have been indirectly determined and the atomic heats of which are probably approximately equal to 6.4:* V, Rb, Sr, Cs, Ba.

IV. *Gaseous elements; specific heats in solid form very doubtful, and apparently variable:* H, (F), N, O, Cl.

It has been already shown that the applica-

tion of Avogadro's law enables a maximum value to be found for the atomic weight of any element which forms one or more compounds gasifiable without decomposition. The maximum value thus found for the atomic weight of aluminium was 54.04; but as this value was based on analyses of only three gaseous compounds, it was asserted that the true value was possibly one-half or one-third, &c. of this number. Now, the specific heat of aluminium has been determined to be .22; hence, assuming the law of Dulong and Petit, the atomic weight of aluminium must be approximately equal to 30 ( $30 \times .22 = 6.6$ ); therefore the value  $\frac{54.04}{3} = 27.01$

is assigned to the atomic weight of this metal. The maximum values assigned to the atomic weights of iron (111.8), copper (126.8), and gallium (138), by the application of Avogadro's law have, in each case, been halved when determinations have been made of the specific heats of these metals.

Various observations on the connexions between the chemical composition and the crystalline form of solid compounds had been made previous to the year 1819, in which year the 'law of isomorphism' was propounded by E. Mitscherlich; this law was subsequently modified and extended, and in 1821 Mitscherlich stated it as follows: 'Equal numbers of atoms similarly combined exhibit the same crystalline form; identity of crystalline form is independent of the chemical nature of the atoms, and is conditioned only by the number and configuration of the atoms.' Further research has shown that Mitscherlich's statement was too absolute. On the one hand, many solid compounds are known, the atomic compositions of which are very similar, and which, nevertheless, crystallise not only in different forms, but in different systems, thus:

PbCrO<sub>4</sub> is monoclinic, but PbMoO<sub>4</sub> is quadratic; AgCl and AgBr are regular, but AgI is hexagonal; KNO<sub>3</sub> is rhombic, but CsNO<sub>3</sub> and RbNO<sub>3</sub> are hexagonal.

On the other hand, many solid compounds crystallise in identical or very similar forms, and nevertheless exhibit unlike atomic compositions; thus the crystalline form of the following salts is the same: K<sub>2</sub>TiF<sub>6</sub>.H<sub>2</sub>O, Cu<sub>2</sub>TiF<sub>6</sub>.4H<sub>2</sub>O, K<sub>2</sub>NbOF<sub>5</sub>.H<sub>2</sub>O, CuNbOF<sub>5</sub>.4H<sub>2</sub>O, K<sub>2</sub>WO<sub>4</sub>.F<sub>2</sub>.H<sub>2</sub>O, CuWO<sub>4</sub>.F<sub>2</sub>.4H<sub>2</sub>O. Many ammonium salts crystallise in the same forms as the corresponding salts of potassium, but the number of atoms in one formula-weight of these salts is different. It is indeed somewhat difficult to give an exact meaning to the expression 'isomorphous crystals;' by this phrase some naturalists mean crystals any one of which is capable of growing in unmodified form when immersed in a solution of any other (*Kopp, B.* 12, 900 *et seq.*); others include crystals belonging to the same system but exhibiting very small differences in the measurements of their angles, *e.g.* the rhombohedral carbonates of magnesium, calcium, iron, zinc, and manganese; others even include crystals which very closely resemble each other but yet belong to different systems. The fact that the same compound may crystallise in two, or even three, distinct forms, further complicates the connexion between isomorphism and

chemical composition; thus, arsenious oxide,  $\text{As}_2\text{O}_3$ , and antimonious oxide,  $\text{Sb}_2\text{O}_3$ , both crystallise in regular octahedra and also in rhombic forms; titanium dioxide,  $\text{TiO}_2$ , crystallises in two forms belonging to the quadratic system, but exhibiting very different relations of crystalline axes, and also in a third form, viz. rhombic prisms.

The constituents of isomorphous compounds are sometimes themselves isomorphous; e.g. the double compounds  $3\text{Ag}_2\text{S} \cdot \text{Sb}_2\text{S}_3$  and  $3\text{Ag}_2\text{S} \cdot \text{As}_2\text{S}_3$  crystallise in identical forms, and the sulphides  $\text{Sb}_2\text{S}_3$  and  $\text{As}_2\text{S}_3$  also crystallise in identical forms. On the other hand, the constituents of isomorphous compounds are sometimes not isomorphous; e.g. the sulphates of magnesium, nickel, and zinc, crystallise in rhombic forms, but the oxides of magnesium and nickel crystallise in regular, and oxide of zinc, in hexagonal, forms. Isomorphism is sometimes not shown in comparatively simple analogous compounds of two elements, while the more complicated analogous compounds of the same elements crystallise in identical or very similar forms; e.g. many of the simpler compounds of cadmium are not isomorphous with the analogous compounds of the magnesian metals ( $\text{Mg}$ ,  $\text{Ca}$ ,  $\text{Mn}$ ,  $\text{Fe}$ ,  $\text{Co}$ ,  $\text{Ni}$ ,  $\text{Zn}$ ,  $\text{Cu}$ ), but the comparatively complex salts of cadmium, such as  $\text{CdSO}_4 \cdot \text{K}_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$ , are usually isomorphous with the analogous salts of the metals named. Hence it is necessary to distinguish strict isomorphism as applied to bodies which exhibit the same or nearly the same crystalline form, from the isomorphism of bodies which, although themselves crystallising in different forms, nevertheless combine with one and the same third body to produce compounds into which they enter as corresponding elements or groups, and which crystallise in the same forms (v. Kopp, *Lehrbuch der Physikal. Chemie*, 2, 141). The crystalline forms of several elements have been determined, but the statement that such or such elements form an isomorphous group usually means only that analogous compounds of these elements are for the most part isomorphous (v. Isomorphism).

Notwithstanding the many qualifying clauses with which any general statement of the connexion between crystalline form and chemical composition must, at present, be guarded, it has frequently been found possible to use the knowledge we have of the connexion in question as a guide in researches concerning the atomic weights of elements.\* In these cases it is assumed that, as a general rule, those masses of two bodies which can mutually replace each other in compounds without change of the crystalline form of the compounds, or in other words those masses which are crystallographically equivalent, have similar atomic compositions. By compounds of similar atomic composition is here meant compounds which are very analogous in their chemical relations, and the formulæ of which contain equal numbers of atoms, or groups of atoms which react through series of changes as if each were a single atom.

Now, if the atomic weight of a specified element is known, and if experiment shows that the mass of this element expressed by its atomic weight is crystallographically equivalent to  $x$  unit masses of another element, it follows

that the value of  $x$  is very probably the value of the atomic weight of the second element. Thus, the facts that gallium sulphate formed a double compound with ammonium sulphate, and that this double sulphate was isomorphous with the alums, indicated that the double sulphate in question was a true alum; hence the general formula which expresses the composition of alums expresses the composition of the double sulphate of gallium and ammonium. The formula in question is  $\text{X}_2\text{SO}_4 \cdot \text{M}_2\text{SO}_4 \cdot 24\text{H}_2\text{O}$ , where  $\text{M}$  = an alkali metal or thallium; but in common alum  $\text{X}_2 = \text{Al}_2 = 2 \times 27.02$  parts by weight of aluminium; and in gallium alum  $\text{X}_2$  was experimentally determined to be 138 parts by weight of gallium. Hence, as two atoms of aluminium were replaced by 138 unit masses of gallium without change of crystalline form, and as the aluminium and gallium compounds were very similar in their chemical relations, the conclusion was drawn that 138 represents the relative weight of two atoms of gallium; therefore the value  $\frac{138}{2} = 69$  was deduced for the atomic weight of gallium. This number was afterwards confirmed by analyses of gaseous gallium chloride, and by determinations of the specific heat of the metal. It was at one time supposed by H. Rose (*P.* 108, 273) that a metal existed closely allied to, but not the same as, niobium; but Marignac (*A. Ch.* 60, 257) found that compounds obtained from this hypothetical metal were isomorphous with the corresponding compounds of tin and titanium, and that the groups of atoms  $\text{SnF}$  and  $\text{TiF}$  could be replaced by an atom of Rose's 'hyponiobium' without change of crystalline form. Hence Marignac suggested that 'hyponiobium' was a compound; and, because of various reactions, that it was a compound of niobium and oxygen in the proportion expressed by the formula  $\text{NbO}$ , where  $\text{Nb}$  has the value 94. If this were admitted it followed that the groups  $\text{NbO}$ ,  $\text{SnF}$ , and  $\text{TiF}$ , were crystallographically equivalent in various compounds; but if so, it also followed, from analyses of the various compounds, that one atom of tin (=117.8 parts by weight), and one atom of titanium (=48 parts by weight), were replaced by 94 parts by weight of niobium in isomorphous compounds; therefore the atomic weight of niobium was 94. This value was confirmed by determinations of the relative densities, and by analyses, of the gaseous chloride and oxychloride of niobium. In this case the comparison of the crystalline forms of compounds led at once to a determination of the atomic weight of an element, to a proof of the non-existence of a hypothetical metal, and to the recognition that a body supposed to be an element was really a compound. An analogous case is furnished by Roscoe's researches on vanadium; in this case also the study of isomorphism led to the correct determination of the atomic weight of vanadium, and to the discovery that the body supposed to be vanadium was in reality a compound of this metal with oxygen (*T.* 1868, 1 et seq.).

No practical definition of the atomic weight of an element can be given in terms of the data of isomorphism. The foregoing examples serve to show how these data are applied to supplement those gained by the analyses of gaseous

compounds, and by determinations of the specific heats, of the elements.

If the atomic weight of calcium is known, then the isomorphism of the carbonates of Mg, Sr, Ba, Pb, Mn, Zn, and Fe, with the carbonate of calcium, helps to fix values for the atomic weights of these 7 elements; the isomorphism of the sulphates of Co, Ni, and Cu, with sulphate of iron gives data from which values may be deduced for the atomic weights of Co, Ni, and Cu; values are found for the atomic weights of Ti and Hg from considering compounds of these elements isomorphous with corresponding compounds of Pb; similarly, Zn and Cd—Fe, Al, and Cr—form many isomorphous compounds; many manganates are isomorphous with selenates and chromates, some chromates are isomorphous with molybdates and tungstates, permanganates are frequently isomorphous with perchlorates and periodates, hence values are found for the atomic weights of Se, Cr, Cl, and I, and also for Mo, and W; from copper we pass to silver through the isomorphism of  $\text{Cu}_2\text{S}$  and  $\text{Ag}_2\text{S}$ ; silver leads on to sodium and the alkali metals on the one hand and to gold on the other hand; the compounds  $\text{RS}_2$  and  $\text{RAS}_2$  are isomorphous, hence conclusions can be drawn regarding the atomic weight of As, and from this the passage is easy to conclusions regarding the atomic weights of P, V, Sb, and Bi; iron is connected with Ti, and this with Si, Zr, Sn, and Th; lastly, given the atomic weight of Pt, Ir, Pd, Ro, Ita, or Os, values can be assigned to the other metals of this group from a study of the composition of isomorphous compounds of these metals. Thus it is seen how helpful is the study of isomorphism in determining the atomic weights of the elements.

These then are the three generally applicable methods whereby values may be found for the atomic weights of the elements: the method founded on the law of Avogadro; the method based on the study of the specific heats of solid elements; and the method which considers the relations between the chemical composition and the crystalline form of similar compounds. The first of these methods can be applied to determine the atomic and molecular weights of elements and the molecular weights of compounds, but the application is restricted to bodies which are gasifiable without decomposition; the second and third methods can be applied, strictly speaking, only to find values for the atomic weights of solid elements or of elements which form solid compounds.

All the methods are essentially physical; they are based on physical conceptions, and they are to a great extent developed by physical reasoning.

The conception of the molecule of a gaseous element or compound which is implied in the statement, 'equal volumes of gases contain equal numbers of molecules,' is wholly physical. The image of the molecule which this statement calls up in the mind is that of a small definite portion of matter 'which moves about as a whole so that its parts, if it has any, do not part company during the motion of agitation of the gas' (Clerk Maxwell). It is when this conception is applied to chemical changes that we are forced to admit that in many of these changes the parts of molecules do part company;

thus we are led to the chemical conception of the atom, as a portion of matter smaller than the molecule, and either itself without parts, or else composed of parts which, so far as we know at present, do not part company during any of the changes which the atom undergoes. Then we proceed to study the properties of these atoms; and among these properties we seem to find two of great importance; the property namely which is expressed in the statement that the atoms of all solid elements, at certain temperatures, have equal capacities for heat; and the property which may be expressed in the statement that identity of crystalline form among compounds is usually accompanied by equality in the number of atoms of which the chemically reacting masses of these compounds are composed.

But here we ask: are the molecules of isomorphous compounds built up of equal numbers of atoms? Can the physical conception of molecule, which has been gained by the study of gaseous phenomena, be applied to solid compounds? And the answer at present is: it is those small masses of isomorphous compounds which take part in chemical reactions, which as a rule, are composed of equal numbers of atoms. The physical definition of molecule cannot, in the present state of knowledge, be safely applied to solid and liquid bodies. Thus we seem to arrive at two conceptions, and two definitions, of the molecule. On the one side we have the physical conception, as that of a small mass of a gaseous element or compound which moves about as a whole, and the parts of which do not part company during the motion of agitation of the gas; and on the other side we have the chemical conception, as that of the smallest mass of an element or compound which takes part in a chemical change, and which exhibits the properties of the specified element or compound.

The first of these definitions holds good whether the small particles of a gas are themselves composed of smaller particles, or are chemically indivisible. The volume occupied by a number of gaseous molecules is independent of the numbers of atoms which by their union form these molecules: in one case a gaseous molecule may consist of a single atom (Hg and Cd), in another case a gaseous molecule may be formed by the union of 2 atoms ( $\text{HCl}$ ), 3 atoms ( $\text{H}_2\text{O}$ ), 9 atoms ( $\text{C}_2\text{H}_6\text{O}$ ), 11 atoms ( $\text{C}_4\text{H}_{10}\text{O}_2$ ), or a much larger number of atoms; but in every case, equal volumes of the gases contain equal numbers of molecules. But we know of no single property of liquid and solid compounds which is similarly independent of the number of atoms forming the atomic complex or reacting chemical unit of the compound.

Let us consider the conception of the chemically reacting unit or collocation of atoms a little more closely. We have already seen that the application of the empirical laws of chemical combination could not lead to final determinations of the atomic weights of elements, because these laws could not enable chemists to determine which of several values should be given to the smallest mass of a compound capable of exhibiting the properties of that compound. The value 8, 16, 21, &c. would be assigned to the atomic weight of oxygen, according as the

'atom' of water—that is, in Daltonian language, the smallest mass of water which exhibits the properties whereby water is distinguished from all other kinds of matter—was assumed to be 9, 18, 27, &c. times heavier than the atom of hydrogen. But a study of the properties of water leads to the conclusion that the 'atom' of water very probably contains two atoms of hydrogen and one of oxygen, and that the atomic weight of oxygen is therefore more probably represented by the number 16 than by the number 8. Thus, if 9 grams of water react with chlorine or bromine in sunlight 8 grams of oxygen are evolved, and 36·5 grams of a compound of hydrogen with chlorine, or 81 grams of a compound of hydrogen with bromine, are produced; in the former case, the 36·5 grams of the chlorine compound are proved by analysis to be composed of 35·5 grams of chlorine and 1 gram of hydrogen; in the latter case, the 81 grams of the bromine compound are proved to be composed of 80 grams of bromine and 1 gram of hydrogen; in both cases the whole of the oxygen of the 9 grams of water is removed from combination with the hydrogen and makes its appearance as free oxygen. Again, if 9 grams of water are acted on by potassium, 5 grams of hydrogen are evolved, and 28 grams of a compound of potassium, hydrogen, and oxygen, containing 8 grams of oxygen—i.e. all the oxygen originally combined with hydrogen in the 9 grams of water—are at the same time produced; if these 28 grams of the new compound are dried, fused, and, while molten, are acted on by potassium, 5 grams of hydrogen are evolved, and 47 grams of a new compound of potassium and oxygen are produced, which 47 grams contain the whole of the oxygen (i.e. 8 grams) originally combined with hydrogen in the 9 grams of water. These experiments prove that the hydrogen in a specified mass of water can be removed from that mass of water in two equal portions, but, so far as these experiments go, that the oxygen in the same mass of water is either not removed at all, or is wholly removed, from combination with hydrogen. Hence the conclusion is drawn that the smallest reacting mass of water contains one chemically indivisible mass of oxygen, but two chemically indivisible masses of hydrogen. But masses of hydrogen and oxygen are combined in water in the ratio 1:8; hence, if the smallest reacting mass of water is composed of 2 smallest parts, i.e. atoms of hydrogen, and one smallest part, i.e. atom, of oxygen, it follows that the atomic weight of oxygen is at least 16, that of hydrogen being unity, and that the relative mass of the smallest reacting portion, that is the *reacting weight*, of water is represented by the number 18, not by the number 9.

What value is to be assigned to the reacting weight of marsh gas? Masses of carbon and hydrogen combine to form marsh gas in the ratio 8:1; hence the value we are seeking cannot be less, but may be greater, than 4. If 4 grams of marsh gas are acted on by chlorine, a series of 4 compounds is produced; the first of these compounds contains chlorine and hydrogen combined with carbon, the masses of carbon and hydrogen being in the ratio 3:75; the second and third contain the same three elements, in the second the carbon and hydrogen are in the

ratio 8:5, and in the third in the ratio 8:35; the fourth is a compound of the whole of the carbon originally combined with hydrogen in the 4 grams of marsh gas with chlorine, and contains no hydrogen. If now 4 grams of marsh gas are burnt in a plentiful supply of oxygen 11 grams of carbon dioxide are produced, or if the same mass of marsh gas is burnt in a limited supply of oxygen 7 grams of carbon monoxide are produced; in each case the oxide of carbon formed contains the whole of the carbon originally combined with hydrogen in the 4 grams of marsh gas used. No compound has yet been obtained from 4 grams of marsh gas containing a smaller mass of carbon than was originally present in the marsh gas, i.e. containing less than 3 grams of carbon. The conclusion drawn from these experiments is that the smallest mass of marsh gas which can take part in chemical changes is itself most probably composed of at least 4 atoms of hydrogen combined with at least one atom of carbon; but if this is granted it follows that an atom of carbon is 12 times heavier than an atom of hydrogen, and that the reacting weight of marsh gas is represented by a number certainly not smaller than 16.

We have thus determined, on chemical grounds and by chemical reasoning, the following values for the atomic weights of two elements: (H=1) C=12, O=16. Now let us consider a compound of these elements. The simplest formula that can be given to acetic acid consistently with the values H=1, C=12, O=16, is  $\text{CH}_3\text{CO}_2$ . If this acid is neutralised by soda, and the sodium salt so formed is analysed, this salt is found to be composed of the same masses of carbon and oxygen, combined with  $\frac{3}{2}$  the mass of hydrogen, which were present in the mass of acid used; hence the smallest reacting mass of acetic acid must contain at least 4 atoms of hydrogen. But if this is granted it follows, from the fact that the elements are combined in the ratio C:2H:O, that this smallest reacting mass must also contain at least 2 atoms of carbon and 2 atoms of oxygen, and that the formula expressing the composition of the reacting weight of the acid in question must be written  $\text{C}_2\text{H}_4\text{O}_2$ . Further evidence in support of this conclusion is afforded by the preparation of thio-acetic acid, which is composed of carbon, hydrogen, oxygen, and sulphur, the carbon and hydrogen being present in the same ratio as in acetic acid, but the oxygen being present in the ratio of 16 to 4 hydrogen (i.e. O:4H), and the sulphur in the ratio 32 to 4 hydrogen. Now the atomic weight of sulphur is almost certainly 32; hence the simplest formula which expresses the composition of the reacting weight of thio-acetic acid is  $\text{C}_2\text{H}_4\text{OS}$ . In this case,  $\frac{1}{2}$  of the oxygen of the reacting weight of acetic acid is replaced by sulphur without any further change in the composition of the acid; hence, there must be at least 2 atoms of oxygen in the reacting weight in question, because atoms are (by definition) chemically indivisible.

This is an example of the general proposition that when  $\frac{1}{n}$  of a constituent element of the reacting weight of a given compound can be replaced by another element without any other

change in the composition of the original substance, it follows that the reacting weight in question must contain at least  $n$  atoms of the element which has been removed; and that if the atomic weight of the replacing element is known, it is easy to calculate, from the composition of the original substance, the masses of the other constituents which must be present united with the  $n$  atoms of the specified element, and hence to assign a minimum value to the reacting weight of the original substance.

When a formula has been assigned to a compound by such chemical methods as those now sketched, it is frequently possible to argue from this to the formulae of similar compounds. Thus, the properties and the methods of formation of sulphide of hydrogen show that this compound is similar to oxide of hydrogen (water); but if the reacting weight of water is represented by the formula  $H_2O$ , that of sulphuretted hydrogen is probably represented by the formula  $H_2S$ ; again, the marked analogies between the sulphide, selenide, and telluride, of hydrogen suggest that these compounds have similar compositions; but if the first named is  $H_2S$ , the others are probably  $H_2Se$ , and  $H_2Te$ , respectively. If these formulae are admitted, values are at once found for the atomic weights of the three elements, sulphur, selenium, and tellurium. Again, the metal magnesium reacts with water in the ratio of 24 parts by weight of the metal to 18 parts by weight of water, the products of this action being, (1) an oxide of magnesium containing 16 parts by weight of oxygen united with 24 parts by weight of magnesium, and (2) two parts by weight of hydrogen; hence, as the reacting weight of water is represented by the formula  $H_2O$ , that of magnesium oxide is probably represented by the formula  $MgO$ , where  $Mg = 24$  parts by weight of magnesium; and hence the atomic weight of magnesium is probably 24.

The chemical methods for determining the atomic weights of elements then lead to a definition of atomic weight which may be stated thus: the atomic weight of an element is a number which tells how many times greater is the smallest mass of that element found in the chemically reacting weight of any of its compounds than the smallest mass of hydrogen found in the chemically reacting weight of any compound of hydrogen, such smallest mass of hydrogen being taken as unity. The difficulty in applying this definition lies in the vagueness of the expression 'the chemically reacting weight of a compound.' This expression cannot be defined; the illustrations already given indicate the interpretation usually put upon it, and also the methods whereby approximately accurate values are obtained for it in special cases.

The physical conception of molecule is clear, and admits of being put into words which have a definite quantitative meaning; this conception leads to that of the atom, the definition of which may also be put into a quantitative form. But the definition of the molecule is strictly applicable only to gases; hence arises the need of a subsidiary definition. We conceive chemical changes occurring among liquid and solid bodies as occurring among the smallest particles of these bodies which are capable of existing as wholes and of exhibiting the properties of the

bodies in question. These smallest particles we may call the chemically reacting units, or the reacting weights, of the bodies; they are generally called molecules; but if we use this term we must not forget that it is employed in a somewhat vague manner, and without the strict quantitative signification which is attached to it when we speak of the molecule of a gas.

It seems probable that the mass of the chemically reacting unit of a compound varies, within certain not very wide limits, in different reactions. This mass must of course always be expressed by a whole multiple of a certain number; but it is probable that the value of the multiple varies. Thus many of the reactions of potassium permanganate can be simply expressed by assigning to the reacting weight of this salt the formula  $KMnO_4$ ; but other reactions indicate that this formula should be doubled and written  $K_2Mn_2O_8$ . Again, periodic acid generally reacts as if the smallest particle which exhibits the chemical properties of this acid had the mass 228, and were composed of hydrogen, iodine, and oxygen, combined as shown in the formula  $H_4IO_7$ ; but some of the reactions of periodic acid are more simply explained by doubling the formula, and writing it  $H_8I_2O_{14}$ . Indeed, even in the case of gaseous elements and compounds, we have sometimes direct evidence to show that the molecular weight of the gas varies with variations of temperature. Consider, for instance, the following data:—

## SPEC. GRAV. OF IODINE GAS (Air = 1).

Pressure	Temperature	Sp. gr.
760 mm.	448°	8.74
"	855	8.07
"	(approx.) { 1275	5.82
"	1470	5.06
76 mm.	{ 1250	4.72

## SPEC. GRAV. OF SULPHUR GAS (Air = 1).

Pressure	Temperature	Sp. gr.
760 mm.	520°	6.62
"	660	2.93
"	860	2.23

(cf. SULPHUR, vol. iv.)

## SPEC. GRAV. OF ACETIC ACID GAS (Air = 1).

Pressure	Temperature	Sp. gr.
760 mm.	124°	3.20
"	130	3.11
"	160	2.48
"	230	2.09
"	280°	2.08
"	338	2.08

## SPEC. GRAV. OF NITROGEN TETROXIDE GAS (Air = 1).

125 mm.	-6°	3.01
138 "	+1	2.84
760 "	70	1.93
" "	135	1.60
" "	185	1.57

The density of iodine gas would be 8.77 if the composition of the molecule were represented by  $I_2$ , and 4.38 if the composition of the molecule were represented by  $I$ ; the numbers given point to the existence of molecules having the composition  $I_2$  at comparatively low

temperatures, and having the composition I at high temperatures when the gas is under a small pressure. The numbers given for sulphur gas suggest the existence of molecules  $S_8$  at temperatures from b.p. to c.  $550^\circ$ , and of molecules  $S_2$  from c.  $650^\circ$  to c.  $1000^\circ$ ; but more recent results throw considerable doubt on the accuracy of this conclusion (*cf.* SULPHUR, vol. iv.) In the case of acetic acid gas, experiments indicate the existence of two different molecules; the data point to the existence of the molecules  $C_2H_3O_2$  (calculated sp. gr. = 2.08, air = 1) at about  $230^\circ$  and upwards, but to the existence of heavier molecules,  $C_2H_5O_2$  (calculated sp. gr. = 3.12, air = 1), at about  $120^\circ$ – $130^\circ$ . Lastly, the existence of the molecules  $N_2O$  (calculated sp. gr. = 3.18) in gaseous nitrogen tetroxide at low temperatures and pressures, and of the molecules  $NO_2$  (calculated sp. gr. = 1.59) at higher temperatures, is indicated by the numbers which represent the observed relative densities of this gas. The sp. grs. of some gases slowly decrease as temperature rises until a value is attained which remains constant throughout a considerable interval, *e.g.* iodine, acetic acid, nitrogen tetroxide, gases; in other cases the sp. gr. remains nearly constant throughout a considerable range of temperature, and then rapidly decreases until another constant value is reached, which again remains constant for a considerable temperature-interval, *e.g.* sulphur gas (*v.* DISSOCIATION, also ALLOTROPY, and ISOMERISM). But in both classes of gases the data point to the existence, at different temperatures, of more or less stable molecules, the mass of the heavier of which is a whole multiple of that of the lighter.

The practical conclusions to be drawn from these facts are, that before the molecular weight of a gas can be regarded as satisfactorily determined, observations of the sp. gr. of that gas must be made throughout a considerable range of temperature; and that the number which represents the sp. gr. in question for such a range of temperature is to be taken as the basis for calculating the molecular weight of the gas, or it may be in some cases the numbers which represent the sp. grs., each for a considerable temperature-interval, are to be used for finding the different molecular weights of the gas.

If then the mass of the molecule of a gas may have a different value, and therefore the molecule be composed of a different number of atoms, at a high than at a low temperature—and so far as data goes it seems that the mass of the molecule, if variable, is greater at temperatures near the condensation point than at temperatures far removed from this point—it is at least very probable that, if we carry over the conception of the molecule from gases to liquids and solids, we must be prepared to regard the mass of the molecule of a liquid or solid compound as considerably greater than that of the molecule of the same compound in the gaseous state. But, in practice, when we speak of the molecular weight of a liquid or solid compound we use the term molecular weight with a meaning different from that which we assign to it when we speak of the molecular weight of a gas. In the latter case the term signifies a small mass of matter, itself built up of smaller parts,

which collides with other similar small masses, rebounds, vibrates, but yet remains intact, when a number of these small parts of matter are heated; in the former case the term summarises a number of chemical data in a convenient form, and asserts that the number of atoms which are so associated as to act in many changes as a chemical whole, is not less than a certain specified number.

The chemical formulæ of solid and liquid bodies do not then stand on the same footing as the formulæ of gases (*v.* FORMULÆ). But the question arises: are these collocations of atoms which we have called reacting chemical units also the reacting physical units of this or that compound? Are the physical constants of compounds conditioned by the masses of these reacting units? If these questions are answered in the affirmative, it is possible that measurements of some physical constant for a series of chemically similar compounds might enable just conclusions to be drawn regarding the relative masses of the reacting units of these compounds. Many measurements of this kind have been made; but no wide generalisation has yet been found which enables us to determine the relative masses of the reacting units of solid and liquid compounds from a knowledge of the physical constants of these compounds. All the generalisations which have been, or which at present can be, ventured upon, are for the most part empirical: the theory of the grained structure of matter has been developed, so far as it has been developed, only for gases; as regards gases, conclusions can be drawn from the fundamental principles of the theory, and these conclusions can be tested by experiment; but as regards liquids and solids, no such general conclusions can be drawn, and the theory can be used as a guide in experimental research only in a wide and general manner. What is wanted now is therefore not only further experimental determinations of the physical constants of series of chemically similar compounds, but a great development of the general theory of the structure of matter, especially in the direction of applying this theory to liquid and solid bodies (*v.* MOLECULAR THEORIES, also PHYSICAL METHODS). The great difficulty lies in the fact that most of the physical constants of liquid and solid compounds appear to be conditioned both by the nature and number, on the one hand, and by the modes of combination, on the other hand, of the atoms which form the atomic complexes we have called reacting chemical units. But the kinetic theory of gases has been chiefly developed from the study of properties which are independent of the nature and number, and are conditioned only by the states of union, of the parts of molecules.

But although we must for a time be content with the conception of the chemically reacting unit of a liquid or solid compound, and although we may at times wistfully contrast this with the clear physical conception of the molecule of a gas, yet there is one well-established chemical generalisation by the application of which values may be obtained for the atomic weights of many elements. This generalisation may be stated thus:—*The properties of the elements vary periodically with variations in the atoms*

weights of the elements; or thus:—If the elements are arranged in order of increasing atomic weights, the properties of the elements vary from element to element, but return more or less nearly to the same values at certain fixed points in the series. Let the elements be arranged in the order of their atomic weights, from hydrogen to uranium; let them be divided, broadly, into series of sevens; let the second series be placed under the first, the third under the second, and so on; then the elements contained in any one vertical column are called a *group*, and those in any one horizontal column are called a *series*. In this arrangement hydrogen is placed in a series by itself, and under it, that is in the same group, is placed the element (lithium) which comes next after hydrogen in order of increasing atomic weight; certain gaps are also supposed to occur in the list of elements, so that an element which immediately succeeds another in order of increasing atomic weights is sometimes placed, not in the group immediately succeeding, but in the group next but one or next but two &c. after, that which contains the element with the smaller atomic weight. Thus uranium (240) comes after thorium (232) in order of atomic weights; thorium is placed in group IV.; but uranium is placed in group VI. Certain elements are also placed in an eighth group by themselves; and the last member of each series in this group is repeated as the first member of the next series in group I.

The following table shows the arrangement of the elements in accordance with the *periodic law*. The formula at the head of each group represents the composition, either of the highest, or of the most characteristic, oxide of the elements belonging to that group; in each case the formula gives the number of atoms of oxygen referred to two atoms of the element.

parts, and to examine the nature of the connexion between the atomic weights, and such measurable properties, of the elements, as atomic volume

$$\left( \text{i.e. the quotient } \frac{\text{atomic weight}}{\text{S.G. of solid element}} \right),$$

position in electrical series, fusibility, composition of oxides, chlorides, &c., wave lengths of characteristic lines in the spectra, heats of combustion or of combination with chlorine, &c. &c. The expression 'properties of the elements' is also to be taken as including the properties of the compounds of the elements; so that the periodic law asserts that *e.g.* the melting-points of similar compounds (say of chlorides) vary periodically with variations in the atomic weights of the elements.

The periodic law will be discussed in detail in the article with that heading; meanwhile suffice it to say that the law rests on a firm basis of well-established facts of diverse kinds. We shall here make use of this law to establish values for the atomic weights of one or two typical elements.

At the time of the publication of Mendelëff's first memoir on the periodic law no elements were known which could be placed in group III. series 4 and 5. Calcium (40) and titanium (48) were known; zinc (65) and arsenic (75) were known: calcium and zinc evidently belong to the group which comprises magnesium, strontium, cadmium, and barium; titanium must be placed in the same group as carbon, silicon, and tin; and arsenic could not be separated from phosphorus, vanadium, and antimony. Hence two gaps occurred in group III. (series 4 and 5), and one in group IV. (series 5). From considering the difference between the values of the atomic weights of consecutive elements, (1) in

In order to establish the existence of a periodic connexion between the atomic weights and the properties of the elements, it is necessary to break up the phenomena connoted by the phrase 'properties of the elements' into

the same series the average value of this difference is about 2 in series 3, 4, and 5—and (2) in the same group—the average value of this difference for the first, second, and third members of groups I., II., and III., and for the first

and second members of groups IV., V., VI., and VII., is about 15, and for the succeeding members of these groups it is about 23—Mendeléeff assigned the value 44 as approximately that of the atomic weight of the unknown element in series 4 of group III., and the value 69 as approximately that of the atomic weight of the unknown element in series 5 of the same group. Mendeléeff also predicted many of the properties of these two unknown elements from considering the positions they occupied in the 'periodic' arrangement of the elements. Thus, the relations of the unknown element with atomic weight 44 to aluminium should be similar to those between (1) calcium and magnesium, (2) titanium and silicon, (3) vanadium and phosphorus, (4) chromium and sulphur; again the relations between (1) beryllium and calcium, (2) carbon and titanium, (3) nitrogen and vanadium, (4) oxygen and chromium, (5) fluorine and manganese, ought to be similar to the relations between boron and the unknown element. As regards the properties of the second unknown element with atomic weight 69, it was known that (1) zinc is more like magnesium than it is like calcium, (2) arsenic more resembles phosphorus than it does vanadium, (3) selenium shows closer analogies with sulphur than with chromium, and (4) bromine and chlorine are more like each other than either is like manganese; hence, it was argued, the unknown element (69) will resemble aluminium more closely than it resembles the other unknown element (44), and more closely than the second unknown element itself resembles aluminium. The relationships indicated were of course studied in detail by Mendeléeff. Thus, take the pairs of consecutive elements in series 3 and 4; the resemblance between any of these pairs (Na, K; Mg, Ca; Si, Ti; P, V; S, Cr; Cl, Mn) is less marked in the higher than in the lower groups. Or, take the two elements in each group belonging respectively to series 3 and 5; the resemblance between any of these pairs (Na, Cu; Mg, Zn; ... P, As; S, Se; Cl, Br) is more marked in the higher than in the lower groups.

The relationships examined by Mendeléeff were those between atomic weights, fusibilities, atomic volumes, composition of oxides, chlorides and other compounds, acid or basic character of oxides, power of forming double salts and composition of these salts if formed, &c. &c. As a result of his study of these relationships, Mendeléeff tabulated many properties of the two unknown elements. Since the memoir of the Russian naturalist was published, several new elements have been discovered; some of the properties of two of these elements will now be compared with the properties which Mendeléeff asserted ought to characterise the elements belonging respectively to series 4 and 5 of group III.

#### Mendeléeff's Eka-aluminium (III.-5).

Atomic weight about 69.  
Readily obtained by reduction.  
Melting-point low. Sp. gr. = 5.9.  
Not acted on by air.  
Will decompose water at a red heat.  
Slowly attacked by acids or alkalis.  
Will form a potassium alum more soluble,

but less easily crystallisable, than the corresponding aluminium salt.

Oxide =  $\text{E}l_2\text{O}_3$ . Chloride =  $\text{E}l_2\text{Cl}_3$ .

#### Gallium.

Atomic weight = 69.

Readily obtained by electrolysis of alkaline solutions.

M.P. =  $30.15^\circ$ . Sp. gr. = 5.93.

Non-volatile, and but superficially oxidised in air at bright red heat.

Decomposes water at high temperatures.

Soluble in hot hydrochloric acid, scarcely attacked by cold nitric acid; soluble in caustic potash.

Forms a well-defined alum.

Chloride =  $\text{Ga}_2\text{Cl}_3$ . Oxide =  $\text{Ga}_2\text{O}_3$ .

#### Mendeléeff's Eka-boron (III.-4).

Atomic weight about 44.

Oxide  $\text{Eb}_2\text{O}_3$  soluble in acids; sp. gr. about 3.5; analogous to but more basic than  $\text{Al}_2\text{O}_3$ ; less basic than  $\text{MgO}$ ; insoluble in alkalis.

Salts of Eb colourless, and will yield gelatinous precipitates with  $\text{KOH}$ ,  $\text{K}_2\text{CO}_3$ ,  $\text{Na}_2\text{HPO}_4$ , &c.

Sulphate,  $\text{Eb}_2\text{SO}_4$ , will form a double salt with  $\text{K}_2\text{SO}_4$ , probably not isomorphous with the alums.

Chloride  $\text{EbCl}_3$  or  $\text{Eb}_2\text{Cl}_3$ , sp. gr. about 2, less volatile than  $\text{Al}_2\text{Cl}_3$ .

#### Scandium.

Atomic weight = 44.

Oxide  $\text{Sc}_2\text{O}_3$ ; sp. gr. = 3.8; soluble in strong acids; analogous with but more decidedly basic than  $\text{Al}_2\text{O}_3$ ; insoluble in alkalis.

Solutions of Sc salts colourless and yield gelatinous precipitates with  $\text{KOH}$ ,  $\text{K}_2\text{CO}_3$ , and  $\text{Na}_2\text{HPO}_4$ .

Sulphate,  $\text{Sc}_2\text{SO}_4$ , forms a double salt, not an alum,  $\text{Sc}_2\text{SO}_4 \cdot 3\text{K}_2\text{SO}_4$ .

Gallium and scandium are, therefore, the elements which Mendeléeff named *eka-aluminium* and *eka-boron*, and many properties of which were accurately and in detail tabulated by him, while the elements were yet unknown.

Much discussion has of late been carried on, and a great deal of experimental work has been done, regarding the value to be given to the atomic weight of beryllium. Chemists are agreed that the value in question is either (in round numbers)  $9 \text{ or } 9 \times 1\frac{1}{2} = 13.5$ ; if the former value is adopted, beryllium must be placed in group II, series 2; if the latter value is preferred, the metal must find a place between carbon and nitrogen. If the former value is adopted, the formula of beryllium oxide becomes  $\text{BeO}$ ; if the latter value is preferred, the formula of this oxide must be written  $\text{Be}_2\text{O}_3$ . The periodic law is a guide in the solution of this problem. Briefly, the law directs us to study the properties of the element itself and the composition and properties of its compounds; to compare these with those of elements which must come in the same group and the same series as beryllium; to compare the relations between beryllium and these other elements with the relations which have been established between elements occurring in positions similar to that occupied by beryllium and the other elements in question; and to adopt

that value for the atomic weight of beryllium which best harmonises with the outcome of this study. There can be no doubt that the value which best harmonises with the results of this study is 9; hence the atomic weight of beryllium is almost certainly 9. This result is confirmed by the application of the law of Dulong and Petit, and also of the law of Avogadro; for the specific heat of beryllium at about 500° is nearly constant and is approximately represented by the number .62 ( $.62 \times 9 = 5.6$ ), and the vapour-densities of beryllium chloride and bromide show that the formulae of these compounds, as gases, are  $\text{BeCl}_2$  and  $\text{BeBr}_2$ , respectively ( $\text{Be} = 9$ ).

The atomic weight of tellurium had for long been supposed to be greater than that of iodine (127); but if this were so tellurium must be placed in group I. series 9; that is to say, in a group which contains the alkali metals. This position cannot be defended; moreover, every chemist knows that tellurium exhibits marked analogies to sulphur and selenium. But if tellurium is to find a place in group VI. the value to be given to its atomic weight must be greater than 120 and less than 127. In 1883 Brauner undertook an experimental criticism of the methods whereby the atomic weight of tellurium had been determined by different chemists. Brauner proved that these methods almost necessarily gave too large values; he also made very careful determinations of the atomic weight of the element by two new methods, and obtained a series of numbers varying from 121.91 to 125.4, with a mean value of 125. The periodic law has, therefore, prevented chemists from finally adopting an erroneous value for the atomic weight of tellurium, notwithstanding the great weight of authority which was in favour of regarding that value as correct.

These examples will suffice to show how the periodic law is used as a guide in determining what multiple of the combining weight of an element is to be adopted as the atomic weight of that element. Incidentally, these examples also impress us with the extreme importance of the constants which we call the atomic weights of the elements. Given this constant for a new element, and we may, to a considerable extent, predict the properties of the element and its compounds. The periodic law also enables values to be given, if not to the molecular weights, then certainly to the reacting weights of compounds; because the position of an element in a group and series determines the formulae of the salts of that element, and, as we assume the atomic weights of the other elements in these salts to be known, therefore determines the relative masses of the chemically reacting units of these salts. There are at least one or two elements in each group which form some gasifiable compounds; the molecular weights of these compounds are therefore known; hence conclusions may tentatively be drawn regarding the molecular weights of similar compounds of other elements in the same group. But no great stress must be placed on such reasoning as this. Aluminium and indium occur in group III. (series 3 and 7), these metals exhibit fairly marked analogies; yet the molecular formula of gaseous aluminium chloride is  $\text{Al}_2\text{Cl}_6$ , while that of gaseous indium chloride is  $\text{InCl}_3$ ; thallium

belongs to the same group as aluminium and indium (series 11), yet the formula of the only chloride of thallium which is stable as a gas is  $\text{TlCl}$ .

There is then at present one generally applicable method for determining the molecular weights of gaseous elements and compounds; this method springs out of the application of the generalisation of Avogadro to chemical changes occurring between gaseous elements. The application of the generalisation in question leads to practical definitions of the terms molecular weight and atomic weight. In addition to this method there are three others which serve to determine, more or less accurately, the values of the atomic weights of the elements; and two of these are also employed to find the relative masses of the small particles of solid and liquid compounds which take part in chemical changes.

The methods founded respectively on the laws of Avogadro, Dulong and Petit, and Mitscherlich, are essentially physical methods; they are outcomes of the physical theory of the grained structure of matter. The applications of this theory to chemical phenomena which have been considered in the present article have been treated in a purely empirical manner. But it is possible to deduce the law of Avogadro from the first principles of the theory in question. The theory assumes that the temperature of a gas represents the mean kinetic energy of the molecules of that gas; hence, if  $M$  and  $M_1$  represent the masses, and  $V^2$  and  $V_1^2$  the mean squares of the velocities, of the molecules of two gases at the same temperature, it follows, from the laws of energy, that

$$MV^2 = M_1V_1^2.$$

But if the pressures of the two gases are equal, then

$$MN^2 = M_1N_1V_1^2;$$

where  $N$  and  $N_1$  represent the number of molecules in unit volume of the two gases; because, according to the theory, the pressure of a gas on the walls of the containing vessel is an effect of the impacts of the molecules of the gas, and this depends on the number and velocity per unit of time of these molecules. From these equations it follows that

$$N = N_1;$$

that is, when two gases are at the same pressure and temperature the number of molecules in unit volume of either gas is the same. But this is the law of Avogadro.

Neither the law of Dulong and Petit, nor the law of isomorphism, can as yet be satisfactorily deduced from the first principles of the molecular theory. We know very little, if anything, of the structure of gaseous molecules; and of the molecular phenomena of solids our accurate knowledge may be said to be almost nothing (*v. Aggregation, States of, p. 87*; also *MOLECULAR STRUCTURE OF MATTER, THEORIES REGARDING*; also *PHYSICAL METHODS APPLIED TO CHEMICAL PHENOMENA*).

The atomic weights of all the known elements have been more or less accurately determined; but only fourteen elements have been gasified, and hence the molecular weights of only fourteen elements have been determined. The molecules of the greater number, but by no means of all,

## ATOMIC AND MOLECULAR WEIGHTS.

these elements are *most probably* (v. remarks on 840 regarding the molecules of hydrogen, &c.) imposed of two atoms; they are diatomic. The following table shows the classification of

the elementary molecules, so far as the available data permit, in accordance with their atomicity, that is, the number of atoms of which each molecule is composed.

ATOMICITY OF ELEMENTARY MOLECULES (the temperatures are approximate).

Monatomic	Diatomic	Triatomic	Tetratomic	Hexatomic
odium otassium inc admium lcury dine at c. 1500° 'Bromine at c. 1800°) ntimony at c. 1700°	Hydrogen Chlorine Bromine Iodine at 200°-1000° Oxygen Sulphur at 800° and upwards Selenium at 1200° and upwards Tellurium Nitrogen Phosphorus } at white Arsenic } heat	Oxygen as ozone Selenium at 700°-800°	Phosphorus Arsenic (both at temps. nearly up to white heat)	Sulphur at 450-550° (very doubtful; v. Biltz a. Meyer, B. 21, 2013)

The following table presents the data available for calculating the molecular weights of the elementary gases:—

MOLECULAR WEIGHTS OF ELEMENTARY GASES.

I.	II.	III.	IV.	V.	I.	II.	III.	IV.	V.

Troost, L. c.<sup>35</sup> Id. 13, 1010.<sup>36</sup> Biltz a. Meyer (Z. P. C. 4, 249) have obtained values<sup>37</sup> which point to a mol. w. for phosphorus between P<sub>4</sub> and P<sub>2</sub>, for bismuth between Bi<sub>2</sub> and Bi, and for thallium as Tl, at<sup>38</sup> very high temperatures.

The following table presents a summary of the atomic weights of the elements and of the evidence upon which each value is based:—

## ATOMIC WEIGHTS OF THE ELEMENTS.

I. Element	II. Principal compounds vapour densities of which have been determined	III. Specific heat : how determined	IV. Isomorphism : compounds compared [see Note A, p. 381]	V. Atomic Weight		VI. Compounds analysed &c. in order to find binding weight of the element [see Note B, p. 361]	VII. Com- bining weight [Note B, p. 361]	VIII. Remarks [see Note C, p. 361]
				(1) By vapour density method	(2) By vapour by sp. heat method			
Hydrogen . .	H <sub>2</sub> , HCl, HBr, HI, H <sub>2</sub> S, H <sub>2</sub> Se, H <sub>2</sub> Te, H <sub>2</sub> N, H <sub>2</sub> P, H <sub>2</sub> C, &c.	Indirectly : from sp. heat of H <sub>2</sub> O, NH <sub>4</sub> Cl, NH <sub>3</sub> , N <sub>2</sub> , &c. Directly heat abnormal[.]	—	1	—	—	—	—
Lithium . .	None	Directly : from sp. heat varies much with tempera- ture	Li compounds with analogous compounds of alkali metals	—	7.01	* Lithium chloride	7.01	—
Beryllium . .	BeCl <sub>2</sub> , BeBr <sub>2</sub>	Directly : sp. heat varies much with tempera- ture	A few Be compounds with analogous compounds of Cd and Zn	9.03	9.03	* Beryllium sulphate	9.03	—
Boron . . .	BF <sub>3</sub> , BCl <sub>3</sub> , BBr <sub>3</sub> , B(CH <sub>3</sub> ) <sub>3</sub>	Directly : sp. heat varies much with tempera- ture	—	10.9	10.9	* Borax ; boron chloride	10.9	—
Carbon . . .	CH <sub>4</sub> , CH <sub>2</sub> F <sub>2</sub> , CH <sub>3</sub> Cl, CH <sub>3</sub> Br, CH <sub>3</sub> I, CH <sub>3</sub> OH, CO, CO <sub>2</sub> , CS <sub>2</sub> , CCl <sub>4</sub> , CBr <sub>4</sub> , C <sub>2</sub> H <sub>2</sub> , C <sub>2</sub> H <sub>4</sub> , C <sub>2</sub> H <sub>6</sub> , C <sub>2</sub> H <sub>4</sub> O, &c.	Directly : sp. heat varies much with tempera- ture	CN compounds with those of F, Cl, Br, and I	11.97	11.97	* Diamond burnt to CO <sub>2</sub>	11.97	—
Nitrogen . .	NH <sub>3</sub> , NO, NO <sub>2</sub> , N <sub>2</sub> O, N <sub>2</sub> O <sub>4</sub> , N <sub>2</sub> O <sub>5</sub> , &c.	Indirectly : very un- decided [from sp. heat of various compounds]	NH <sub>3</sub> compounds with those of alkali metals	14.01	—	* Ammonium chloride ; silver nitrate	14.01	—
Oxygen . . .	OH, ON, OC, O <sub>3</sub> , O <sub>2</sub> , O <sub>4</sub> , O <sub>8</sub> , &c.	Indirectly : very un- decided [from sp. heat of various compounds]	—	15.96	—	* Synthesis of water	15.96	—
Fluorine . .	HF, F(OH), F <sub>2</sub> , F <sub>2</sub> O, F <sub>2</sub> SO <sub>2</sub> , F <sub>2</sub> SO <sub>3</sub> , &c.	Indirectly : very un- decided [from sp. heat of CaF <sub>2</sub> , &c.]	Metallic fluorides with analogous compounds of Cl, Br, and I	19.1	—	* Sodium fluoride ; potassium fluoride ; calcium fluoride ; sodium chloride	19.1	—
Sodium . . .	None	Directly	Na compounds with those of other alkali metals	—	23	* Sodium chloride	23	—
Magnesium . .	"	"	Mg compounds generally with those of Zn, Mn, and Fe (in ferrous salts)	—	24	* Magnesium sulphate, do chloride	24	—
Aluminium . .	AlCl <sub>3</sub>	"	With Cr, Mn, and Fe in B <sub>2</sub> O <sub>3</sub> and derivatives	27.02	27.02	* Ammonia - alum ; aluminium bromide ; solution of alu- minium in soda	27.02	—

I. Element	II. Principal compounds vapour densities of which have been determined	III. Specific heat: how determined	IV. Isomorphism: compounds compared [see Note A, p. 381]	V. Atomic Weight		VI. Compounds analysed &c. in order to find combining weight of the element [see Note B, p. 381]	VII. Combining weight [Note B, p. 381]	VIII. Remarks [see Note C, p. 381]
				(1) By vapour-density method	(2) By vapour-density method			
Strontium . .	None	Indirectly: doubtful [in comparison of compounds of Sr, Ca, and Ba]	Sr compounds with those of Ca and Ba, and with some Pb salts	—	—	" Strontium chloride	43.65	Sr. The atomic weight of strontium must be taken as $43.65 \times 3 = 87.3$ if the formulae of the salts are the second analogues to those of the Ba compounds.
Yttrium . . .	"	Sp. heats of a few compounds determined	Yt compounds with those of other earth metals	—	—	" Synthesis of yttrium sulphate	29.87	Yt. Atomic weight probably = $29.87 \times 3 = 89.6$ because of analogy of Yt salts with those of the earth metals
Zirconium . .	ZrCl <sub>4</sub>	Directly [? too low]	ZrO <sub>2</sub> with TiO <sub>2</sub> , ThO <sub>2</sub> , SnO <sub>2</sub> , and SiO <sub>2</sub>	90	90	" Zirconium chloride; potassium zirconium fluoride	46	
Niobium . . .	NbCl <sub>5</sub> , NbOCl <sub>3</sub>	—	Nb with Ta compounds, Nb fluorides and oxyfluorides with Mo do. do.	94	—	" Niobium chloride; potassium niobium oxyfluoride	31.33	
Molybdenum	MoCl <sub>5</sub>	Directly [? too high]	Mo do. do. compounds: some MoO <sub>3</sub> with those of H, CrO <sub>3</sub> , Mo with Nb fluorides and oxyfluorides	95.8	95.8	" Molybdenum dichloride, molybdenum pentachloride, and pentachloride	19.16	
Ruthenium . .	RuO <sub>4</sub>	Directly	Most Ru compounds with those of Rh, Pd, Ir, Pt, and Os	101.4	101.4	" Potassium-ruthenium chloride, &c.	25.38	
Rhodium . . .	None	"	Most Rh compounds with those of Ru, Pd, Ir, Pt, and Os	—	102.7	" Potassium-rhodium chloride	25.65	
Palladium . .	"	"	Most Pd compounds with those of Ru, Rh, Ir, Pt, and Os	—	106.3	" Palladium chloride	26.58	
Silver . . . .	AgCl	"	Some Ag compounds with those of Na and other alkali metals. Ag with Cu compounds of the Rh. A few Ag and Au compounds	107.66	107.66	" Silver chlorate, bromate, iodate; synthesis of silver bromide and iodide	107.66	
Cadmium . . .	CdBr <sub>2</sub>	"	Some Cd compounds with those of Be and Zn	112	112	" Cadmium bromide	66	
Indium . . . .	InCl <sub>3</sub> , InCl, InCl <sub>2</sub>	"	Some In compounds with those of Cd and Pb	113.4	113.4	" Synthesis of indium oxide	37.8	
Tin . . . . .	SnCl <sub>4</sub> , SnCl <sub>2</sub> , SnCl	"	SnO <sub>2</sub> with TiO <sub>2</sub> , ZrO <sub>2</sub> , and ThO <sub>2</sub>	117.8	117.8	" Synthesis of stannic chloride	58.9	
Antimony . .	SbCl <sub>5</sub> , SbBr <sub>3</sub> , SbI <sub>3</sub> , Sb(CH <sub>3</sub> ) <sub>3</sub> , Sb <sub>2</sub> O <sub>3</sub> , SbCl <sub>3</sub>	"	Sb compounds with those of As and Bi	120	120	" Antimony bromide; reduction of antimony oxide; also analysis of antimony sulphide	40	

Tellurium . . .	TeH <sub>4</sub> , TeCl <sub>4</sub> , TeCl <sub>5</sub>	Directly	Most Te compounds with those of S and Se	125	125	44 Oxidation of tellurium : potassium-tellurium bromide; synthesis of basic tellurium sulphate and of copper telluride	62.5
Iodine . . .	IH, IO, I(CH <sub>3</sub> ), I.P., I.Hg, I.P., I.As, I.Sb, I.Al, &c.	"	Iodides with analogous compounds of Cl and Br	125.53	125.53	44 Silver iodate; silver iodide; synthesis of do.	125.83
Cesium . . .	CaCl	Indirectly : doubtful (comparison of compounds with those of other alkali metals)	Ca compounds with those of other metals of alkalis	132.7	—	44 Cesium chloride	132.7
Barium . . .	None	Indirectly : doubtful (comparison of compounds with those of Ca, Sr, Ba)	Ba compounds with those of Ca and Sr	—	—	44 Barium chloride	68.4
Lanthanum . . .	"	Directly	Most La compounds with those of Ce, Di, Er, and Yt. Some compounds of these metals with Ca compounds	—	138.5	44 Lanthanum sulphate; do. oxalate; do. oxalate; do. sulphate	46.17
Cerium . . .	"	"	Most La compounds with those of Ce, Di, Er, and Yt. Some compounds of these metals with Ca compounds	—	139.9	44 Cerium oxalate; do. sulphate; do. sulphate	46.6
Didymium . . .	"	"	Most La compounds with those of Ce, Di, Er, and Yt. Some compounds of these metals with Ca compounds	—	144	44 Didymium oxide and sulphate	43
Erbium . . .	"	"	Most La compounds with those of Ce, Di, Er, and Yt. Some compounds of these metals with Ca compounds	—	(142)	44 Erbium sulphate	(47.6)
Ytterbium . . .	"	Sp. heats of a few compounds determined	{ A few Yb compounds with those of other earth metals }	—	—	44 Ytterbium sulphate	57.63
Tantalum . . .	TaCl <sub>5</sub>	—	Ta with Nb compounds	182	—	44 Potassium-tantalum fluoride; ammonium-tantalum fluoride	60.67
Tungsten . . .	WOCl <sub>4</sub> , WCl <sub>6</sub>	Directly	W with Mo compounds. Some salts of H <sub>2</sub> WO <sub>4</sub> with those of H <sub>2</sub> CrO <sub>4</sub> and H <sub>2</sub> FeO <sub>4</sub>	183.8	183.8	44 Reduction of tungstic oxide; tungsten tetrachloride	30.6

Er. Atomic weight is 68.4 × 2 = 136.8, based on the difference between atomic weights of Ba, Sr, and Ca

Er. This metal belongs to the earthy group, and its atomic weight is taken as 68.4 × 3 = 166.16. For similar reasons to those which apply in cases of Se, Yt, and Er, the atomic weight of Ytterbium is supposed to be 3 times its combining weight = 173

### Notes to Table of Atomic Weights.

A. As the method based on isomorphism of compounds is chiefly used as a means of verifying values assigned to atomic weights by other methods, no numbers are given in column IV., but merely an indication of the various compounds which have been compared crystallographically, and on which arguments for or against a given value for the atomic weights in column V. have been, or may be, based.

B. This column (VI.) is not to be regarded as containing anything like a complete summary of the processes employed for determining the combining weights of the elements; only the more important processes are indicated—references are given to the original papers.

By combining weight is here meant the smallest mass of the element which combines with 8 parts by weight of oxygen, 1 part of hydrogen, or 35.5 parts of chlorine.

A complete account of all researches on this subject will be found in *A Recalculation of the Atomic Weights*, by F. W. Clarke [Part v. of the *Constants of Nature* published by the Smithsonian Institution], and also in *Die Atomgewichte der Elemente*, by L. Meyer and K. Seubert [Leipzig, 1883].

C. When the atomic weight given in column V. section (2) is a multiple of the combining weight in column VII., no number being given in section (1) of column V., it is to be inferred that, besides the argument drawn from the value of the specific heat of the element in question, there are other chemical reasons for adopting the special multiple which appears in V. (2); these reasons may be broadly described as based on analogies between salts of the given element and salts of other elements the atomic weights of which have been established by the two leading physical methods. M. M. P. M.

ATOMICITY. Term used to denote number of atoms in any specified gaseous molecule, usually in the molecule of an element.

ATOMIC VOLUMES v. PHYSICAL METHODS; sect. VOLUMETRICAL.

**ATRACYLIC ACID**  $C_{10}H_{10}S_2O_{16}$ . Potassium atractylate  $K_2A'''$  occurs in the root of *Atractylis gummifera*, from which it may be extracted by boiling 70 p.c. alcohol (Lefranc, *Bl.* [2] 11, 499; *J. Ph.* [4] 9, 81; 10, 325; 17, 187, 263; *C. R.* 67, 954; 76, 438). Boiling potash hydrolyses it, forming valeric acid and so-called ( $\beta$ )-atractylic acid,  $C_{10}H_{10}S_2O_{16}$ , which is further split up into  $H_2SO_4$ , valeric acid and atractylin.

**ATRACYLIN**  $C_{20}H_{30}O_6$ . From '( $\beta$ )-atractylic acid' by boiling with aqueous KOH. White gummy substance, with sweet taste, v. sol. water and alcohol, insol. ether and aqueous NaCl. Forms a violet-red solution in warm  $H_2SO_4$ . Boiling KOH forms atractyligenin and a saccharine substance.

**ATRANORIC ACID**  $C_{18}H_{18}O_8$ . [190°–194°]. Extracted by ether from certain lichens [*Lecanora atra*, *Stereocaulon vesuvianum*, *Cladonia rangiformis*]. Trimetric crystals;  $a:b:c = 1:398:306$ ; sl. sol. alcohol, cold ether, and benzene; m. sol. hot benzene; sol. alkalis forming a yellow solution. Heated with water in a sealed tube it splits up into atranorinic acid,  $C_8H_8O_4$ , and atraric acid,  $C_{10}H_{10}O_4$  (Paternd,

*G.* 9, 279; 10, 157; 12, 256; Coppola, *G.* 12, 19).

**ATRANORINIC ACID**  $C_8H_8O_4$ . [101°]. Formed by heating atranoric acid (*q. v.*) with water. Needles, m. sol. water, sol. alcohol and ether. Its alkaline solutions are yellow. Its aqueous solutions give a green pp. with  $AgNO_3$ , a brownish-green colour with  $FeCl_3$ , and a blood-red colour with bleaching-powder (Paternd, *G.* 12, 256).

**ATRARIC ACID**  $C_{10}H_{10}O_4$ . [141°]. Produced by heating atranoric acid with water (Paternd, *G.* 12, 257). Iridescent laminae, sl. sol. water, m. sol. alcohol and ether. Its alkaline solutions are colourless. It gives a brownish pp. with  $AgNO_3$  and no colour with  $FeCl_3$ .

**ATRIPAIC ACID**  $C_8H_8O_{12}6aq$ . [98° when hydrated]. An acid obtained from the sugar cane (Savary, *C. C.* 1884, 968).

*Ethyl ether* (184°–188°).

**ATROGLYCERIC ACID**  $C_9H_8O_4$ , i.e.  $CH(OH).CPh(OH).CO.H$ . [146°].  $\alpha\beta$ -Di-oxy- $\alpha$ -phenyl-propionic acid. From  $\alpha\beta$ -di-bromo- $\alpha$ -phenyl-propionic acid and excess of alkali (Kast, *A.* 206, 30). Crystalline aggregates, sol. water and ether. Salts.— $CaA'$ ,  $BaA'$ .

*Nitrile*  $CH_2OH.CPh(OH).CN$ . [57°]. From benzoyl-carbinol and HCN (Plochl, *A. Blümlein*, *B.* 16, 1292).

**ATROLACTIC ACID** v.  $\alpha$ -OXY- $\alpha$ -PHENYL-PROPIONIC ACID.

**ATROLACTYL-TROPEINE**  $C_{11}H_{11}NO_6C_8H_7O_2$ . *Pseudo-atropine*. [121°]. Crystalline solid. Very similar in physiological action to atropine. Formed by the action of dilute HCl on tropine atrolactate.

Salts.—Mostly soluble.— $HCl$ ,  $AlCl_3$ ; sparingly soluble tables. The picrate also forms sparingly soluble tables (Ladenburg *a. Roth*, *B.* 15, 1027; *A.* 217, 87).

**ATRONENE**  $C_{14}H_{14}$ , i.e.  $C_6H_5 \begin{matrix} \diagup CH_2-CH \\ | \\ CPhH.CH \end{matrix}$ .

*Phenyl-naphthalene dihydride*. (325° i.v.) Formed, together with atronic acid, by the dry distillation of ( $\alpha$ )- or ( $\beta$ )-iso-atropinic acid (Fittig, *A.* 206, 51). Liquid. *Chromic acid* oxidises it to *o*-benzoyl-benzoic acid.

**Atronene sulphonic acid**  $C_{16}H_{16}SO_3H$ . [130°]. Needles; v. sol. water.— $BaA''$ ,  $CaA''$ , 2aq.

**ATRONIC ACID**  $C_{17}H_{14}O_2$ , i.e.

$C_6H_5 \begin{matrix} \diagup CH(CO.H) \\ | \\ CPhH.CH \end{matrix} CH$  (?) *Phenyl-naphthalene di-hydride carboxylic acid* (?). [164°]. Formed, together with atronene by the dry distillation of ( $\alpha$ )- or ( $\beta$ )-iso-atropinic acid (Fittig, *A.* 206, 46). Prisms; insol. water, sol. alcohol and glacial HOAc. Salts.— $CaA'$ , 6aq.— $BaA'$ , 4aq.

**Iso-atronic acid**  $C_{17}H_{14}O_2$ . [157°]. Obtained by heating ( $\alpha$ )- or ( $\beta$ )-iso-atropinic acid with conc.  $H_2SO_4$  (Fittig, *A.* 206, 86). Leaflets, insol. water, sol. alcohol, ether, and glacial HOAc.

Salts.— $CaA''$ ,  $BaA''$ , 6aq.

**ATRONYLENE SULPHONIC ACID**

$C_8H_{11}SO_3H$ . [c. 258°]. Formed by heating ( $\alpha$ )- or ( $\beta$ )-iso-atropinic acid or iso-atronic acid with 9 pts. conc.  $H_2SO_4$  at 90° (Fittig, *A.* 206, 60). Prisms (from 50 p.c. acetic acid). Insol. water, v. sol. alcohol. The aqueous solutions of its salts when exposed to sunlight deposit small

needles of atronyl-sulphone  $C_{11}H_{11}SO_2$ . [193°].

**ATROPIC ACID**  $C_8H_8O_2$ , i.e.  $CH_3.CPh.CO_2H$ .  
 $\alpha$ -Phenyl-acrylic acid. M. w. 148. [107°].  
 (203°) at 75 mm. S. 141 at 19°.

**Formation.**—1. By boiling atropine with baryta (Richter, *J. pr.* 11, 33; Kraut, *A.* 128, 282; Fittig a. Wurster, *A.* 195, 147). 2. By heating atropine with fuming HCl at 120° (Lossen, *A.* 138, 230). 3. By the action of HCl on ethyl-tropic acid,  $CH_3.CPh(OEt).CO_2H$ , obtained from acetophenone chloride by alcoholic KCN and saponification (Ladenburg a. Rügheimer, *B.* 13, 2041).—4. By action of boiling NaOH upon  $\alpha$ -chloro- $\beta$ -phenyl-propionic acid which is formed by the action of HCl upon acetophenone cyanhydrin or by heating  $\alpha$ -oxy- $\alpha$ -phenyl-propionic acid with saturated HClAq at 130° (Spiegel, *B.* 14, 237; 1354).

**Properties.**—Needles (from water) or monoclinic prisms (from alcohol); v. sol.  $CS_2$ .

**Reactions.**—1. *Chromic acid mixture* forms benzoic acid.—2. *Potash-fusion* forms phenyl-acetic acid.—3. *Sodium-amalgam* reduces it to  $\alpha$ -phenyl-propionic acid.—4. Fuming HCl forms  $\alpha$ -chloro- $\alpha$ -phenyl-propionic acid, which is converted by aqueous  $Na_2CO_3$  at 120° into tropic acid,  $CH_3(OH).CPhH.CO_2H$ .—5.  $ClOH$  forms chloro-tropic acid  $CH_2(OH).CPhCl.CO_2H$  (Ladenburg a. Rügheimer, *B.* 13, 376).—6. Cold conc.  $HBr$ Aq forms both  $\alpha$ , and  $\beta$ , bromo- $\alpha$ -phenyl-propionic acid; at 100° it forms only  $\beta$ -bromo- $\alpha$ -phenyl-propionic acid.—7. *Bromine* forms  $CH_2Br.CPhBr.CO_2H$ .

**Salts.**—Neutral atropates are not ppd. by manganese salts (difference from cinnamates).— $CaA_2$  5aq (K.).— $CaA_2$  2aq (L.).

(a)-**Iso-atropic acid**  $C_8H_8O_2$  (?). [237°].

**Preparation.**—(a), and ( $\beta$ ), isoatropic acids are both formed when atropic acid is heated alone or with water; they may be separated by crystallisation from 50 p.c. acetic acid.

**Properties.**—Crystalline aggregates, sl. sol. boiling water, sol. alcohol. *Chromic acid* gives anthraquinone and *o*-benzoyl-benzoic acid. V. also ATRONENE, ATRONIC ACID, and ATRONYLENE SULPHONIC ACID.

**Salts.**— $CaA''$  2aq.— $BaA''$  2 $\frac{1}{2}$ aq.

*Ethyl ether EtA''* (180°).

( $\beta$ )-**Iso-atropic acid**  $C_8H_8O_2$ . [206°]. Rectangular tables (from water). More soluble in water, alcohol, and HOAc than the ( $\alpha$ ) acid. Gives the same reactions as the ( $\alpha$ ) acid.

**Salts.**— $CaA''$  3aq (Fittig, *A.* 206, 34; *B.* 12, 1739; compare R. Meyer, *A.* 219, 290).

**ATROPINE**  $C_{17}H_{23}NO_3$ , i.e.

$CH_3.OH.CPhH.CO.O.CH_2.CH_2.C_2H_5.NMe$ .

*Datuvine*. [114°]. S. 33.

**Occurrence.**—Together with hyoscyamine in all parts of *Atropa belladonna* (Geiger a. Hesse, *A.* 5, 43; 6, 44; Mein, *A.* 6, 67), and in the seeds of *Datura stramonium* (Geyger, *A.* 7, 272; Planta, *A.* 74, 245).

**Formation.**—Crystalline tropine tropate has no action on the eyes, but when treated with dehydrating agents, such as  $ZnCl_2$ ,  $Ac_2O$ , or HCl, atropine is formed. It is best to evaporate frequently with very dilute HCl at 100° (Ladenburg, *A.* 217, 78; *B.* 12, 912; 13, 104,

909; *C. R.* 90, 921). Tropine contains hydroxyl which is etherified by tropic acid:

**Preparation.**—Dry belladonna leaves are digested for three days with cold water, the extract is evaporated, and after mixing with  $Na_2CO_3$  the syrupy liquid is agitated with benzene. The benzene solution is decanted off and shaken with dilute sulphuric acid. The acid liquid is rendered alkaline with  $Na_2CO_3$  and the solution agitated with chloroform; the extract is filtered and, after addition of light petroleum, allowed to evaporate spontaneously, when the atropine separates out first, the mother liquors containing another alkaloid (Pesci, *G.* 10, 426).

**Properties.**—Needles (from dilute alcohol). Sl. sol. water; v. sol. alcohol, and chloroform, m. sol. ether. The solutions are alkaline to test-paper, and taste bitter. Its salts enlarge the pupil of the eye. .05 to .2 g. is a fatal dose. Three drops of a 1 p.c. solution of (artificial) atropine enlarges the pupil to the maximum extent. Atropine overcomes the stoppage of the heart's action produced by muscarine.

**Reactions.**—1. When evaporated to dryness with fuming  $HNO_3$  a residue is left which is turned violet by alcoholic KOH.—2. *Chromic acid mixture* forms benzoic acid.—3. A solution in HCl gives with gold chloride an oily pp. that quickly changes to lustreless crystals which melt under water or, when dry, at 136°.—4. *Tannin* gives, in very dilute neutral solutions a white pp., sol. HCl.—5. *Potassio-mercuric iodide* gives a white cheesy pp.—6. I in KI gives a brown oil which solidifies after some time.—7. *Picric acid* gives, in somewhat dilute acid solutions, a crystalline pp.—8. Conc.  $H_2SO_4$  gives, on warming, a pleasant odour.—9. *Cyanogen* gas passed into an alcoholic solution gives, after some time, a red colour.—10. *Chloride of iodine* forms a dark yellow pp., sol. on warming, and separating out on cooling in brown crystals (Dittmar, *B.* 18, 1612).—11. Decomposed by hot baryta-water or cold conc. HCl into tropic acid and tropine (Kraut, *A.* 128, 280; 133, 87; 148, 240; Lossen, *A.* 138, 230).—12. Hot conc. HClAq at 120° gives tropine, tropic acid, atropic acid, iso-atropic acids, and (at 180°) tropidine.—13. With  $NaNO_3$ ,  $H_2SO_4$ , and subsequently NaOH a violet colour is developed.—14. Glacial HOAc and  $H_2SO_4$  produce on prolonged warming a greenish-yellow fluorescence (Flückiger, *Ph.* [3] 16, 800).—15.  $H_2SO_4$  and  $KClO_3$  give a greenish-blue colour (Vitali, *Ph.* [3] 12, 459).

**Salts.**— $B'HAuCl_4$  [135°–137°].— $B'H_2PtCl_6$  [208°].— $B'TlCl_2HgCl_2$  (Gerrard, *Fr.* 24, 601).  $B'HI_{12}$ ; brown prisms (Jørgensen, *Z.* 5, 673).— $B'HI_{12}$ .— $B'H_2SO_4$ ; needles, got by adding an ethereal solution to an alcoholic solution of  $H_2SO_4$ . Valerate  $B'CO_2H_10O_2$  1aq [42°] (Callmann, *J. pr.* 76, 629).

**Additional References.**—Günther, *J.* 1869, 781; *Fr.* 8, 476; Lefort, *Ph.* [3] 2, 1029; *C. C.* 1873, 797; Brunner, *B.* 6, 96; Newark, *C. C.* 1872, 536; Guiliemo, *Fr.* 2, 404; Ludwig, *Ar. Ph.* [2] 107, 129; Schmidt, *A.* 208, 196.

*Ethyl-atropine*  $C_{17}H_{23}EtNO_3$ . Formed by action of  $Ag_2O$  on its hydriodide,  $B'HI$ , obtained

by heating atropine with EtI at 100° (Lossen, *A.* 188, 289). A syrup, sol. water.

**Apoatropine**  $C_{17}H_{21}NO_2$ . [60°–62°]. Formed by treating atropine with  $HNO_3$  (Pesci, *G.* 11, 588; 12, 60). Prisms; sl. sol. water, v. s. sol. alcohol. Decomposed by baryta-water at 100° into tropine and atropic acid. Does not enlarge the pupil. Salts.— $B^+HAuCl_4$  [180°] amorphous.— $B^+H_2SO_4$ , 5aq.

**Pseudo-atropine v. ATROLACTYL-TROPEINE.**

**Hydro-apo-atropine**  
 $CH_3CHPh.CO.O.CH_2CH_2.C_6H_5.NMe$ . Prepared by the action of nascent hydrogen on apo-atropine (Pesci, *Atta d. Acad. dei Lincei*, 5, 329). Oil. Decomposed by baryta-water at 100° into  $\alpha$ -phenyl-propionic acid and tropine. Forms a crystalline compound with  $HgCl_2$ . Neutral  $KMnO_4$  oxidises it to 'homo-apo-atropine'  $C_{17}H_{21}NO_2$ , an alkaline oil which forms the following salts:  $B^+CO_3$ ,  $B^+H_2PbCl_4$ ,  $B^+HAuCl_4$ ,  $B^+H_2SO_4$ , 2aq,  $B^+H_2PdCl_4$ ; its hydrochloride gives white pps. with tannin, Mayer's reagent, and  $HgCl_2$ ; and it gives a blood-red colour with fuming  $HNO_3$ ; heated with baryta-water it gives  $\alpha$ -phenyl-propionic acid and tropigenine (Pesci, *G.* 12, 285, 329; Merling, *B.* 15, 289).

**Homo-atropine v. PHENYLGLYOXYL-TROPEINE.**

**Meta-atropine v. TROPINE.**

**ATROPYL-TROPEINE**  $C_{17}H_{21}NO_2$ . *Anhydro-atropine*. Obtained by heating tropine hydrochloride with atropic acid and  $HCl$  (Ladenburg, *A.* 217, 102; *B.* 13, 1085). Oil.— $B^+HAuCl_4$ ; small needles.

**ATROXINDOLE v. o-AMIDO- $\alpha$ -PHENYL-PROPIONIC ACID**, p. 179.

**AURANTIIN**  $C_{23}H_{30}O_{12}$  4aq. [171°]. S. -33.  $[\alpha]_D^{20} = -64.57^\circ$ . A glucoside in the flowers of *Citrus decumana* (K. Hoffmann, *B.* 9, 691). Yellow monoclinic prisms. Bitter taste. Gives a brownish-red colour with  $FeCl_3$ .

**AURATES.** Auric hydroxide  $Au_2O_3.H_2O$  ( $=Au_2O_3.H_2O$ ) reacts with  $HNO_3$  to form the compound  $Au(NO_3)_3.HNO_3.3H_2O$ ; from this several basic nitrates and one or two sulphates of gold may be produced (Schottländer, *A.* 217, 312). But  $Au_2O_3.H_2O$  also dissolves in  $KOHAq$ , and on evaporation at a gentle heat and finally *in vacuo*, crystals are obtained, which when dissolved in water, recrystallised, drained, and dried *in vacuo*, are said to have the composition  $Au_2O_3.K_2O.3H_2O$  ( $=Au_2O_3.K_2.3H_2O$ ). Aurate of potassium is very soluble in water, forming an alkaline liquid which is easily decomposed by organic compounds and by heat; the solution gives pps. with solutions of various metallic salts, e.g.  $CuCl_2$ ; these pps. are said to be aurates, but very little is known about their composition. An aurate of ammonium of indefinite composition, known as *fulminating gold*, is formed by pptg. a solution of a gold salt by excess of  $NH_4Aq$ , and boiling in  $NH_4Aq$ ; or by digesting  $Au_2O_3.H_2O$  in  $(NH_4)_2SO_4Aq$  (Fremy, *A. Ch.* [3], 31, 480; Figuier, *id.* [3] 11, 341). M. M. P. M.

**AURIC ACID.** The hydrated oxide of gold  $Au_2O_3.H_2O$  is sometimes called auric acid because of its salt-forming reactions with alkalis (*supra*). This compound is best prepared by adding  $NaOHAq$  to very dilute  $AuCl_3Aq$ , in the ratio  $9NaOH:AuCl_3$  (the  $AuCl_3Aq$  should be prepared in about the ratio  $AuCl_3:800H_2O$ ); warming till the liquid is dark brown; adding  $Na_2SO_4Aq$ ;

allowing pp. to settle; washing repeatedly by decantation, and then on a filter, until the washings are free from  $H_2SO_4$  and  $HCl$ ; boiling pp. with conc.  $HNO_3Aq$ ; and again washing free from acid (Thomson, *Tk.* 3, 891). According to Krüss (*B.* 19, 2546),  $Au_2O_3.H_2O$  is better prepared from  $AuCl_3Aq$  by pptg. with *magnesia alba*, boiling with dilute  $HNO_3Aq$ , washing with water, and drying over  $P_2O_5$ .  $Au_2O_3.H_2O$  is easily soluble in  $HBrAq$  and  $HClAq$ , with production of much heat, and formation of  $AuCl_3Aq$  and  $AuBr_3Aq$  respectively (v. Gold). M. M. P. M.

**AURINE v. ROSOLIC ACID.**

**AUSTRALENE v. TURPENTINE OIL.**

**AXIN v. AGE**, p. 87.

**AZAMMONIUM COMPOUNDS.** Compounds obtained by oxidising mono-alkylated o-amido-azo compounds, or by heating azimido-compounds with alkyl iodides followed by moist  $Ag_2O$  (Zincke a. Lawson, *B.* 20, 1173). Thus  $C_{10}H_7.N:N.C_6H_4.NH.C_6H_5$  gives, on oxidation with chromic acid,  $C_{10}H_7.N_2O$  which might be expected to have the formula:

Naphthalene-di-phenyl-azammonium hydrate

The chromate is obtained by the oxidation of benzene-azo-phenyl-( $\beta$ )-naphthylamine

It is converted into the chloride by boiling with alcohol and  $HCl$  till all the chromic acid is reduced. The hydrate is obtained from the chloride by  $Ag_2O$ . Its solution has a greenish fluorescence, is strongly alkaline, and tastes bitter; it decomposes on evaporation.

**Salts.**—Like the base, they have a greenish fluorescence in aqueous and alcoholic solution, and a bitter taste. —  $C_{22}H_{19}.N_2.Cl$ : glistening prisms, v. sol. alcohol, less in water; it forms sparingly soluble double chlorides with  $SnCl_2$ ,  $ZnCl_2$ ,  $HgCl_2$ , &c.— $(C_{22}H_{19}.N_2.Cl)_2PtCl_4$ : sl. sol. crystalline pp. —  $C_{22}H_{19}.N_2.HSO_3$ : glistening transparent needles or prisms, v. sol. hot alcohol, sl. sol. cold water. —  $C_{22}H_{19}.N_2.NO_2$ : long flat glistening needles, v. sol. hot alcohol, sl. sol. water. —  $(C_{22}H_{19}.N_2)_2Cr_2O_7$ : long yellow needles, sol. acetic acid, v. sl. sol. water. —  $*(C_{22}H_{19}.N_2)_2C_6H_5(NO_2)_2O$ : [243°]; small yellow needles, v. sl. sol. water (Zincke a. Lawson, *B.* 20, 1172).

**AZARONE**  $C_{17}H_{16}O$ . [59°]. (296°). S.G.  $\frac{1}{4}$  1.165;  $d_4^{20}$  1.0743. Obtained by distilling the rhizomes of *Azaron europaeum* with steam (Boutleff a. Rizza, *Bl.* [2] 43, 114). White crystalline body, sl. sol. water, sol. alcohol, ether  $CCl_4$ , and acetic acid. Combines with  $Br$ , forming  $C_{17}H_{16}Br_2O$ .

**AZAUROLIC ACIDS.**

**Ethyl-azaurolic acid**  $C_8H_{15}N_3O$ . [142°]. From ethyl nitrolic acid (2 g.) by the action of water and sodium amalgam. The yield (25 g) is bad. Formed also by reducing di-nitro-ethane (V. Meyer a. Constam, *A.* 214, 330; *B.* 14, 1455). **Properties.**—Orange-red prisms (from alco-

hol). M. sol. hot alcohol, sl. sol. ether, v. sl. sol. water, chloroform, benzene or light petroleum. Alkalis form a deep orange solution. At 142° it melts, with decomposition, leaving a liquid which, after solidifying, melts again at 133°.

**Reactions.**—1. Ammoniacal solution gives with AgNO<sub>3</sub> a brown pp., and with salts of Zn or Pb, yellow pps. A solution of the ammonium salt deposits, on evaporation, needles of the free acid.

2. Heat, dilute acids, nascent hydrogen, and ammonia all convert it into ethyl-leucazone;  $2C_2H_5N_2O + H_2O = C_2H_5N_2O + O + NH_3$ , the oxygen converting another portion of ethyl-azaurolic acid into acetic acid, N, and N<sub>2</sub>O.—3. K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and H<sub>2</sub>SO<sub>4</sub> give acetic acid and CO<sub>2</sub>.

**Constitution.**—Its formation from ethyl-nitrolic acid indicates the group  $MeC \begin{smallmatrix} N \\ < \end{smallmatrix}$ , and the presence of Me.C is shown by the production of acetic acid on oxidation. Ethyl-azaurolic acid would then be  $Me.CH \begin{smallmatrix} N \\ < \end{smallmatrix} O$  or, more probably,  $Me.CH(NO).N.N.CH(NO)Me$  or perhaps  $MeC(NO).N.NH.CMe:NOH$ .

**Ethyl-leucazone** C<sub>2</sub>H<sub>5</sub>N<sub>2</sub>O. [158°]. Formed together with nitrogen, N<sub>2</sub>O, and hydroxylamine by heating ethyl-azaurolic acid with dilute HCl (M. a. C.). Satiny needles. Reddens litmus. Combines with acids, bases, and salts. V. sol. alcohol or water, insol. ether. Its aqueous solution is turned red by FeCl<sub>3</sub> and oxidised to acetic acid by K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and H<sub>2</sub>SO<sub>4</sub>.

**Salts.**—B<sup>+</sup>.H<sub>2</sub>SO<sub>4</sub>: [161-5°]; prisms, sol. ordinary (90 per cent.) alcohol.—Ba(C<sub>2</sub>H<sub>5</sub>N<sub>2</sub>O)<sub>2</sub>—C<sub>2</sub>H<sub>5</sub>N<sub>2</sub>OAgNO<sub>3</sub>.

**Propyl-azaurolic acid** C<sub>3</sub>H<sub>7</sub>N<sub>2</sub>O. [127-5°]. From propyl-nitrolic acid by sodium-amalgam.

#### AZELAIC ACIDS C<sub>8</sub>H<sub>14</sub>O<sub>4</sub>

##### n-Azelaic acid

CO<sub>2</sub>H.CH<sub>2</sub>.CH<sub>2</sub>.CH<sub>2</sub>.CH<sub>2</sub>.CH<sub>2</sub>.CH<sub>2</sub>.CH<sub>2</sub>.CO<sub>2</sub>H. [118°]. Formed by reducing butyro-furonic with HI and P (Tönnies, B. 12, 1200). Slender needles (from chloroform).

**Azelaic acid** C<sub>8</sub>H<sub>14</sub>O<sub>4</sub>. *Anchoic acid*. *Lep-argylic acid*. Mol. w. 188. [106°]. (above 360°). S. 108 at 12°; S. (ether) 1-88 at 11°.

**Formation.**—1. By the oxidising action of HNO<sub>3</sub> upon Chinese wax (Buckton, C. J. 10, 166), cork, oleic acid (Laurent, A. Ch. [2] 64, 154), cocoa-nut oil (Wirz, A. 104, 265), castor oil (Arppe, A. 120, 288; Gantner a. Hell, B. 14, 560, 1545), and eminoic acid (Kraft, B. 11, 1415).—2. From oleic and KMnO<sub>4</sub>Aq (Saytzeff, J. pr. [2] 33, 301).

**Preparation.**—Castor oil is oxidised by HNO<sub>3</sub> (S.G. 1-25). Heptonic acid is distilled off with steam, and the hot residual liquor poured off from a heavy nitrogenous oil. On cooling, suberic and azelaic acids crystallise. Pure suberic acid is got by washing the mixed acids with ether, which dissolves azelaic acid as well as oily impurities. The ether is evaporated, the residue dissolved in boiling water and NaCl added. Oily matter then separates and azelaic acid crystallises from the brine (Dale a. Schorlemmer, C. J. 35, 684; cf. Gantner a. Hell, B. 14, 1545).

**Properties.**—Large thin plates, not volatile with steam. Sol. water, alcohol, and ether. Nitric acid oxidises it to succinic acid. It does not give a homologue of suberone when distilled

with slaked lime, hence its constitution is probably not analogous to that of the homologous suberic acid.

**Salts.**—K.A": small plates.—K.A" 2aq: needles.—KHA".—KH<sub>2</sub>A".—Na.A" aq: soluble plates.—Na<sub>2</sub>HA".—(NH<sub>4</sub>)<sub>2</sub>A": large plates.—(NH<sub>4</sub>)HA".—Ba.A" aq: S. 65 at 16°; 628 at 100°.—Sr.A" aq.—Ca.A": crystalline powder; S. 185 at 17°; 193 at 100°.—Mg.A" 3aq.—Mn.A" 3aq: slender needles; S. 206 at 14°; 108 at 100°.—Ni.A" 6aq.—Co.A" 6aq.—Zn.A": crystalline pp.; S. 026 at 12°.—Pb.A": white pp.; S. 006 at 24°.—Ag.A": white pp.; S. 0015 at 14°.—Cu.A"—Fe(OH).A" 2aq.—Cd.A".

*Ethyl ether* Et.A". Decomposed on boiling.

**AZIDINES.** Compounds related to hydrazines (q. v.) in the same way that amidines are related to amines. Thus the hydrochloride of phenyl-hydrazine acting on a solution of benzimido-ether in absolute alcohol produces dark red needles of di-phenyl-benz-azidine, Ph.C(NH.NPhH):N.NPhH; while form-imido-ether gives, when similarly treated, di-phenyl-formazidine CH(NH.NPhH):N.NPhH [185°] (Pinner, B. 17, 182, 2002).

**AZIMIDO-COMPOUNDS.** This term was originally applied by Griess (B. 15, 1878) to the compounds obtained by the action of nitrous acid upon ortho-diamines, which are probably

of the form  $R'' \begin{smallmatrix} N \\ < \end{smallmatrix} NH$ , and was extended by Zincke (B. 18, 3134) to compounds, probably of

the form  $R'' \begin{smallmatrix} N \\ < \end{smallmatrix} NR'$ , got by oxidising o-amido-azo-compounds (hydrazimido-compounds). The first formula may also be written  $R'' \begin{smallmatrix} NH \\ < \end{smallmatrix} N$ ,

which stands to  $R'' \begin{smallmatrix} NH_2 \\ < \end{smallmatrix} N$  in the relation that diazobenzene anilide stands to a mixture of diazobenzene chloride and aniline.

**Azimido-benzene** C<sub>6</sub>H<sub>3</sub>N<sub>3</sub>, i.e. C<sub>6</sub>H<sub>4</sub>  $\begin{smallmatrix} N \\ < \end{smallmatrix} NH$

or C<sub>6</sub>H<sub>4</sub>  $\begin{smallmatrix} NH \\ < \end{smallmatrix} N$ . [99°]. From aqueous o-phenylene-diamine sulphate and KNO<sub>2</sub> (Ladenburg, B. 9, 222). Needles (from benzene).

**Azimido-nitro-benzene** C<sub>6</sub>H<sub>3</sub>N<sub>3</sub>O<sub>2</sub>, i.e.

C<sub>6</sub>H<sub>3</sub>(NO<sub>2</sub>)  $\begin{smallmatrix} N \\ < \end{smallmatrix} NH$  or C<sub>6</sub>H<sub>3</sub>(NO<sub>2</sub>)  $\begin{smallmatrix} NH \\ < \end{smallmatrix} N$  [211°].

Formed by passing nitrous acid into a solution of nitro-o-phenylene diamine (Hofmann, Pr. 10, 406). Long white prisms, v. sol. alcohol and ether, sl. sol. cold water. Nitrous acid does not affect it, hence it does not contain NH<sub>2</sub>.

**Salts.**—C<sub>6</sub>H<sub>3</sub>KN<sub>3</sub>O<sub>2</sub>—C<sub>6</sub>H<sub>3</sub>AgN<sub>3</sub>O<sub>2</sub>. Not affected by boiling HCl, or KOH.

**Azimido-toluene** C<sub>7</sub>H<sub>3</sub>N<sub>3</sub>, i.e.

CH<sub>3</sub>.C<sub>6</sub>H<sub>3</sub>  $\begin{smallmatrix} N \\ < \end{smallmatrix} NH$  or CH<sub>3</sub>.C<sub>6</sub>H<sub>3</sub>  $\begin{smallmatrix} NH \\ < \end{smallmatrix} N$ .

[83°]. (823°). From aqueous tolylene-o-diamine sulphate and KNO<sub>2</sub> (L.). Prisms containing C<sub>7</sub>H<sub>3</sub> (from toluene). V. sol. alcohol, m. sol. ether and boiling water. Not affected by HClAq

at 160°. Salts.—B'HCl: decomposed by water. —B'H<sub>2</sub>PtCl<sub>6</sub>.

**Acetyl derivative** C<sub>6</sub>H<sub>4</sub>AcN<sub>2</sub>. [180°]. From acetyl-*o*-tolylene diamine, HCl, and NaNO<sub>2</sub> (Boessneck, B. 19, 1758). Needles.

(*β*)-Azimido-benzoic acid C<sub>6</sub>H<sub>3</sub>N<sub>2</sub>O<sub>2</sub> i.e.

From the hydrochloride of di-amido-benzoic acid, CO<sub>2</sub>H.C<sub>6</sub>H<sub>3</sub>(NH<sub>2</sub>)<sub>2</sub> [1:3:4] and KNO<sub>2</sub> (Griess, B. 2, 436). Also by the action of boiling potash upon C<sub>6</sub>H<sub>3</sub>(CO<sub>2</sub>H)(NO<sub>2</sub>)(NH.CO.NH<sub>2</sub>) [1:3:4] and upon C<sub>6</sub>H<sub>3</sub>(CO<sub>2</sub>H)(NO<sub>2</sub>)(NH.CO.NH<sub>2</sub>) [1:4:3] (Griess, B. 15, 1880). This seems to indicate the symmetrical formula. Short needles, containing water of crystallisation; v. sl. sol. water. Not attacked by warm fuming HNO<sub>3</sub>.

(*γ*)-Azimido-benzoic acid. Prepared similarly from CO<sub>2</sub>H.C<sub>6</sub>H<sub>3</sub>(NH<sub>2</sub>)<sub>2</sub> [1:2:3]. Long hair-like needles (G.).

**Azimido-benzene-*γ*-carboxylic ether** C<sub>6</sub>H<sub>3</sub>N<sub>2</sub>O<sub>2</sub>

[73°]. From the hydrochloride of *o*-amido-phenyl carbamic ether and KNO<sub>2</sub> (Rudolph, B. 12, 1295).

**Phenyl-azimido-naphthalene**

Soluble in hot acetic acid, sparingly in alcohol and benzene. Formed by oxidation of benzene-azo-(*β*)-naphthylamine with CrO<sub>3</sub> in acetic acid solution. It is not attacked by strong H<sub>2</sub>SO<sub>4</sub>, acetic anhydride, or reducing agents (Zincke, B. 18, 3136).

***o*-Oxy-phenyl-azimido-naphthalene**

silky needles. Easily soluble in alcohol and benzene. Formed by oxidation of an alkaline solution of *o*-oxy-benzene-azo-(*β*)-naphthylamine with lead peroxide. It is not attacked by strong H<sub>2</sub>SO<sub>4</sub>, acetic anhydride, acetyl chloride, or reducing agents (Z.).

***p*-Oxy-phenyl-azimido-naphthalene**

or white needles. Soluble in hot alcohol and hot acetic acid, sparingly in benzene. Formed by oxidation of an alkaline solution of *p*-oxy-benzene-azo-(*β*)-naphthylamine with lead peroxide. It is not attacked by reducing agents.

**Acetyl derivative**

plates (Z.).

**Tolyl-azimido-toluene** C<sub>11</sub>H<sub>13</sub>N<sub>2</sub> i.e.

**Formation.**—1. By oxidation of *p*-toluene-*o*-azo-*p*-toluidine [1:4] C<sub>6</sub>H<sub>4</sub>.Me.N<sub>2</sub>.C<sub>6</sub>H<sub>4</sub>.Me(NH<sub>2</sub>) [4:1:2].—2. By heating the imide of *o*-diazo-toluene-azo-toluene or by boiling its acetic acid solution, N<sub>2</sub> being evolved.—3. Together with an

amido-phenol or diamine by reducing with SnCl<sub>2</sub>, the azo compounds obtained by combining *o*-diazo-toluene-azo-toluene with phenols or amines (Zincke a. Lawson, B. 19, 1455; 20, 1178).

**Properties.**—Thin colourless plates. Sol. benzene, hot alcohol, and hot HOAc. Not attacked by hot Ac<sub>2</sub>O, cold H<sub>2</sub>SO<sub>4</sub>, or reducing agents.

**AZINES.** Compounds of the type

sented by the formula

or

and the nomenclature of other azines may be gathered from two examples (Hinsberg, B. 20, 21).

**Derivatives of quinoxaline**

are called quinoxalines, e.g. tolu-quinoxaline

**Formation.**—1. From *o*-diamines and *o*-quinones or *o*-di-oxy-compounds.—2. By oxidation of a mixture of *o*-diamine and phenols (e.g. (*β*)-naphthol).—3. By boiling certain azo-dye-stuffs, derived from secondary amines, with dilute acids; e.g. sulpho-benzene-azo-phenyl-(*β*)-naphthyl-amine yields naphtho-phenazine and sulphanilic acid C<sub>6</sub>H<sub>4</sub>(SO<sub>3</sub>H) N<sub>2</sub>C<sub>6</sub>H<sub>4</sub>.NHC<sub>6</sub>H<sub>3</sub> = C<sub>6</sub>H<sub>4</sub> $\begin{array}{c} \diagup \text{N} \diagdown \\ \diagdown \text{N} \diagup \end{array}$ C<sub>6</sub>H<sub>3</sub> + C<sub>6</sub>H<sub>4</sub>(SO<sub>3</sub>H).NH<sub>2</sub> (Witt, B. 20, 571).—4. By fusing *o*-quinones with ammonium acetate, or by heating them with alcoholic NH<sub>3</sub> (Japp, C. J. 51, 100).

**Properties.**—Weak crystalline bases; their salts being decomposed by water. Reduced by SnCl<sub>2</sub> to hydrides, R $\begin{array}{c} \diagup \text{NH} \diagdown \\ \diagdown \text{NH} \diagup \end{array}$ R', whence Fe<sub>2</sub>Cl<sub>6</sub> regenerates the original azine.

**Azine-ammonium bases.** Compounds of the

Azonium bases (Witt, B. 20, 1183), a term previously applied by Fischer to quaternary hydrazine derivatives.

**AZINSUCCINIC ACID**  
( $\text{CO}_2\text{H}$ ),  $\text{C}_6\text{H}_2\text{N}_2\text{N}:\text{N}:\text{C}_6\text{H}_2(\text{CO}_2\text{H})_2$ . Crystalline solid. Very soluble in water and alcohol. Not decomposed by acids or alkalis. The ethers of this acid are obtained by the spontaneous decomposition of the ethers of diazosuccinic acid  $\text{C}_6\text{H}_2\text{N}_2(\text{CO}_2\text{Et})_2$  on keeping, half the nitrogen being evolved.  $\text{A}^*\text{Ba}_2$ : sparingly soluble yellowish-white powder.

*Tetra-methyl-ether*  $\text{A}^*\text{Me}_4$ : [150°]; silky white prisms; easily soluble in hot water and alcohol, sparingly in cold water, alcohol, and hot ether; not volatile with steam (Curtius a. Koch, B. 18, 1299).

**AZO-ANILINE** v. Amido-benzene-azo-aniline under Azo-compounds.

**AZO-BENZENE** v. Benzene-azo-benzene under Azo-compounds.

**TRIAZO-BENZENE** and its derivatives v. DIAZO-BENZENE IMIDE and its derivatives.

**AZO-BENZOIC ACID** v. Carboxy-benzene-azo-benzoic acid under Azo-compounds.

#### AZO-COLOURING MATTERS.

*History.*—The series of compounds comprised under this class contains one or more diatomic groups  $\text{N}:\text{N}$  linking together acid or basic aromatic radicles. Of a very large number of azo-compounds known to science only a certain proportion are of technical value, and these are manufactured in large quantities owing to their importance as colouring matters. The first azo-compound introduced into commerce was the oxalate of amidoazobenzene ('aniline yellow,' v. benzene-azo-aniline),  $\text{C}_6\text{H}_5\text{N}_2\text{C}_6\text{H}_4\text{NH}_2$ , manufactured in 1863 by the firm of Simpson, Maule & Nicholson, by the action of nitrous gas on aniline dissolved in alcohol. Three years later triamidoazobenzene,  $\text{NH}_2\text{C}_6\text{H}_4\text{N}_2\text{C}_6\text{H}_4(\text{NH}_2)_2$  (v. Amido-benzene-azo-phenylene-diamine under Azo-compounds), was manufactured at Manchester and introduced under the name of 'Manchester brown' ('Bismarek brown,' 'Phenylene brown,' 'Vesuvine'). This compound was prepared by the action of nitrous acid upon *m*-phenylene-diamine. In 1875 diamidoazobenzene,  $\text{C}_6\text{H}_5\text{N}_2\text{C}_6\text{H}_4(\text{NH}_2)_2$  (v. Benzene-azo-phenylene-diamine), was discovered independently by Caro and Witt (B. 10, 213, 350) and introduced into commerce by the latter under the name of 'chrysoidine.' These basic colouring-matters were soon followed by acid azo-compounds of greater technical value (B. 10, 1378, 1509), and numerous patents have since that time been taken out, the general mode of preparation being similar in principle to that first employed in 1870 by Kekulé and Hidegh (B. 3, 233). These are the chief points in the industrial history of these compounds; the chemical history will be referred to under the individual compounds. Azo-benzene,  $\text{C}_6\text{H}_5\text{N}_2\text{C}_6\text{H}_5$  (v. Benzene-azo-benzene), which may be regarded as the prototype of the azo-compounds, has been known since 1834 (Mitscherlich, A. 12, 311), but the industrial development of these products is largely due to the researches of Griess upon the diazo-compounds (A. 106, 123; 113, 201; 117, 1; 120, 125; 121, 257; 137, 39). The theoretical views which have led to the adoption of the formulae at present generally received have been developed chiefly by Kekulé (Z. 1866, 2, 309, 689).

*Formation.*—1. Compounds of the azoben-

zene type are produced by the action of mild reducing agents, such as alcoholic potash, alcoholic KOH and zinc dust, iron and acetic acid, or sodium stannite, upon the corresponding nitro-bodies:  $2\text{C}_6\text{H}_5\text{NO}_2 + 4\text{H}_2 = \text{C}_6\text{H}_5\text{N}_2\text{C}_6\text{H}_5 + 4\text{H}_2\text{O}$ .

2. By the oxidation of the corresponding amido-derivatives by potassium permanganate, bleaching powder, chromic acid, hydric peroxide, &c., thus:  $2\text{C}_6\text{H}_5\text{NH}_2 + \text{O}_2 = \text{C}_6\text{H}_5\text{N}_2\text{C}_6\text{H}_5 + 2\text{H}_2\text{O}$  (Glaser, Z. [2] 2, 308). This method is applicable to the sulphonic acids and other derivatives of the amido-compounds:  $2\text{C}_6\text{H}_4(\text{CH}_3)\text{HSO}_3\text{NH}_2 + \text{O}_2 = \text{N}_2(\text{C}_6\text{H}_4\text{CH}_3)_2 + 2\text{H}_2\text{O}$  [illustrating the production of azotoluenedisulphonic acid from toluenedisulphonic acid; Kornatzki, A. 221, 179].

3. By the action of ethyldichloramine (Tscherniak, B. 9, 147) upon certain aromatic amines (e.g. *p*-toluidine):  $2\text{C}_6\text{H}_5\text{NH}_2 + \text{C}_2\text{H}_5\text{NCl}_2 = \text{C}_6\text{H}_5\text{NH}_2\text{HCl} + \text{HCl} + \text{C}_6\text{H}_5\text{N}_2\text{C}_6\text{H}_5$  (Pierson a. Heumann, B. 16, 1048).

4. By the action of nitroso-compounds upon amines and phenols:  $\text{C}_6\text{H}_5\text{NO} + \text{H}_2\text{N}.\text{C}_6\text{H}_5 = \text{C}_6\text{H}_5\text{N}_2\text{C}_6\text{H}_5 + \text{H}_2\text{O}$  (production of azobenzene from nitrosobenzene and aniline; Baeyer, B. 7, 1638). Similarly  $\text{HO}.\text{C}_6\text{H}_4.\text{NO} + \text{H}_2\text{N}.\text{C}_6\text{H}_5 = \text{HO}.\text{C}_6\text{H}_4.\text{N}_2\text{C}_6\text{H}_5 + \text{H}_2\text{O}$  (production of benzene-azophenol from nitrosophenol and aniline; Kimich, B. 8, 1026). According to Henriques, substituted amidoazo-compounds are produced by the action of ethyl- $\beta$ -naphthyl-nitrosamine upon aniline, &c.:  $\text{N}(\text{C}_6\text{H}_5)_2\text{Et}.\text{NO} + \text{H}_2\text{N}.\text{C}_6\text{H}_5 = \text{N}(\text{C}_6\text{H}_5)_2\text{Et}(\text{N}_2\text{C}_6\text{H}_5) + \text{H}_2\text{O}$ . The diazo-compound immediately becomes transformed into the isomeric benzeneazo-ethyl- $\beta$ -naphthyl-amine,  $\text{C}_6\text{H}_5\text{N}_2\text{C}_{10}\text{H}_7\text{NH}.\text{Et}$  (B. 17, 2668, v. also O. N. Witt, B. 10, 1309). Amidoazobenzene reacts in a similar manner with the same nitrosamine forming  $\text{C}_6\text{H}_5\text{N}_2\text{C}_6\text{H}_4\text{N}_2\text{C}_6\text{H}_5\text{NH}.\text{Et}$ .

5. From azoxy-compounds by intramolecular transposition, such as the formation of oxy-azobenzene (benzene-azo-phenol) by warming azoxybenzene with strong sulphuric acid:  $\text{C}_6\text{H}_5\text{N}=\text{N}^+\text{O}^- + \text{C}_6\text{H}_5\text{N}_2\text{C}_6\text{H}_4.\text{OH}$  (Wallach a. Belli, B. 13, 525).

6. By the action of phenylhydrazine upon the naphthoquinones:  $\text{C}_{10}\text{H}_6\text{O}_2 + \text{H}_2\text{N}.\text{NH}.\text{C}_6\text{H}_5 = \text{C}_{10}\text{H}_6\text{N}=\text{N}^+\text{O}^- - \text{NH}.\text{C}_6\text{H}_5 + \text{H}_2\text{O}$ . The naphthoquinonehydrazide then undergoes intramolecular transposition with the formation of an azo-compound:  $\text{HO}.\text{C}_6\text{H}_4.\text{N}:\text{N}.\text{C}_6\text{H}_5$ . The compound thus obtained from (c)-naphthoquinone is identical with benzene-azo-(a)-naphthol, while (b)-naphthoquinone gives a compound which is isomeric and not identical with benzene-azo-(b)-naphthol (Zineke a. Bindewald, B. 17, 3026).

*Preparation.*—The method in general use for the preparation of azo-colours is that depending upon the readiness with which diazo-compounds react with amines and phenols. In practice it is not necessary to isolate the diazo-salt, but the amido-compound which is to be converted into a diazo-salt is treated with the necessary quantity of sodium nitrite and acid to diazotise the  $\text{NH}_2$  group, and the solution of the diazo-salt is then mixed with the solution of the amine in acid or the phenol dissolved in alkali. During the process of diazotising, the solution containing the amido-compound must be kept well cooled, as the diazo-salts are very unstable,

especially in aqueous solution. Most aromatic amido-compounds lend themselves to this reaction, the azo-colours of commerce being produced by the action of diazotised amines, amido-sulphonic acids, or amido-carboxylic acids, upon amines, phenols, amido-sulphonic and oxy-sulphonic acids. A selection of typical reactions illustrating the formation of these compounds by the present method may be here conveniently discussed:

(a) When a salt of diazobenzene acts upon aniline the first product of the reaction is always diazobenzeneanilide (diazobenzenamide):  $C_6H_5.N_2.Cl + C_6H_5.NH_2 = C_6H_5.N_2.NH.C_6H_5 + HCl$ . The latter compound was first produced by the action of nitrous gas upon aniline dissolved in cold alcohol (Griess, *A.* 121, 258). When allowed to stand in the presence of aniline and aniline hydrochloride, or when acted upon by hydrochloric acid or unstable metallic chlorides in the cold, the diazobenzeneanilide is slowly converted into the isomeric amidoazobenzene,  $C_6H_5.N_2.C_6H_5.NH_2$ . This last compound is manufactured on a commercial scale for the preparation of other azo-colours and the indulines (*q. v.*). In the case of other amines in which the para-position with respect to the  $NH_2$  group is open (or the ortho-position in the naphthalene series), the transformation of diazo- into amidoazo-compounds takes place with great readiness. Thus, by the action of nitrous acid upon *o*- and *m*-toluidine, *m*-xyldine and the naphthylamines, amidoazo-compounds are at once formed.

(b) The salts of the aromatic diazo-compounds react with primary and secondary monamines, but not with tertiary monamines of the fatty series. The resulting products are diazo-compounds, such as  $C_6H_5.N_2.NH.C_2H_5$  (diazobenzene-ethylamide) and  $C_6H_5.N_2.N(CH_3)_2$  (diazobenzenedimethylamide). The diazo-compounds of this class do not furnish isomeric azo-compounds (Bacayer and Jäger, *B.* 8, 148). True azo-compounds of a mixed aromatic and fatty type are produced by the action of diazo-compounds upon the sodium derivatives of nitro-hydrocarbons of the fatty series, *e.g.*

(formation of benzeneazonitroethane, V. Meyer and Pupils, *B.* 8, 751, 1073, 1078; 9, 384; 12, 2285).

(c) Diazo-compounds always furnish true azo-compounds with secondary and tertiary aromatic monamines, such as  $C_6H_5.N_2.C_6H_4.NMe_2$  (benzene-azo-dimethylaniline) by the action of diazobenzene upon dimethylaniline (Griess, *B.* 10, 528), and  $C_6H_5.N_2.C_6H_4.NH.C_6H_5$  (benzene-azo-diphenylaniline) by the action of diazobenzene upon diphenylaniline (Witt, *B.* 12, 259, and *C.* 35, 185).

(d) The action of diazo-compounds upon aromatic diamines is typified by the action of diazobenzene-chloride upon *m*-diamidobenzene to produce chrysidine:  $C_6H_5.N_2.Cl + C_6H_4(NH_2)_2 = C_6H_5.N_2.C_6H_4(NH_2)_2.HCl$ . Nitrous acid gives with ortho-diamines a class of substances termed by Griess azimido-compounds:

(Hofmann, *A.* 115, 249; Ladenburg, *B.* 11, 219;

Rudolph, *B.* 12, 1296; Griess, *B.* 15, 1878). Metadiamines give under the same circumstances compounds of the type of triamidoazobenzene (Bismarck brown)  $2C_6H_4(NH_2)_2 + HNO_2 = (NH_2)_2C_6H_3.N_2.C_6H_4(NH_2)_2 + 2H_2O$  (Caro a. Griess *Z.* 1867, 278). By acting with an excess of  $HNO_2$  upon *p*- and *m*- $C_6H_4(NH_2)_2$  in acid solution with suitable precautions both these diamines can be diazotised and give azo-colours when combined with phenols (Griess, *B.* 17, 607 and 19, 317).

(e) The formation of azo-colours from diazo-compounds and phenols as illustrative of the general method of technical production is shown by the following typical examples:  $C_6H_5.N_2.NO_2 + C_6H_5.ONa = C_6H_5.N_2.C_6H_4.OH + NaNO_2$  (benzeneazophenol from diazobenzene nitrate and sodium phenate: Kekulé and Hldegh, *B.* 3, 233). By a similar reaction would be formed such compounds as benzeneazoresorcin,  $C_6H_5.N_2.C_6H_4(OH)_2$  (Typke, *B.* 10, 1576), benzene-azo-( $\alpha$ )-naphthol,  $C_6H_5.N_2.C_{10}H_7.OH$ , &c. (*ibid.* 1580). Azosulphonic acids are formed by the action of diazosulphonic acids upon phenols, or by the action of diazo-salts upon phenolsulphonic acids, thus, for example, *p*-sulphobenzene-azo- $\beta$ -naphthol (Poirrier's 'Orange No. II'),  $HSO_3.C_6H_4.N_2.C_{10}H_7.OH$  from diazo-benzene sulphonic acid and sodium ( $\beta$ )-naphtholate; benzene-azo-( $\beta$ )-naphthol disulphonic acid,  $C_6H_5.N_2.C_{10}H_7(HSO_3)_2.OH$  from diazo-benzene and ( $\beta$ )-naphthol sodium disulphonate ('Orange G,' Meister, Lucius a. Brining), or *p*-sulphobenzene-azo-( $\beta$ )-naphthol disulphonic acid,  $HSO_3.C_6H_4.N_2.C_{10}H_7(HSO_3).OH$  from diazotised sulphanilic acid and ( $\beta$ )-naphtholdisulphonic acid sodium salt (Meldola, *B.* 13, 942).

*Classification and Nomenclature.*—Azo-compounds may be described as primary, secondary, tertiary, &c. according as they contain 1, 2, 3, &c.  $N_2$ -groups. The modes of formation above described have been illustrated by reference to primary azo-compounds, all of which (with the exception of the mixed aromatic and fatty compounds) may be regarded as derivatives of azobenzene,  $C_6H_5.N_2.C_6H_5$ , benzeneazonaphthalene,  $C_6H_5.N_2.C_{10}H_7$ , and azonaphthalene,  $C_{10}H_7.N_2.C_{10}H_7$ , or generally, in the case of phenolic azo-compounds, as  $R.N_2.Pl$ , where  $R$  may stand for  $C_6H_5$ ,  $C_{10}H_7$ ,  $C_6H_4.HSO_3$ ,  $C_6H_4.NO_2$ , &c., and  $Pl$  for  $C_6H_5.OH$ ,  $C_6H_4.OH$ ,  $C_{10}H_7(HSO_3).OH$ , &c. It will be found convenient to write the formulae of azo-compounds so as to represent the order of introduction of the radicles. Thus,  $C_6H_5.N_2.C_6H_4.OH$  indicates the product from diazobenzene and phenol, and would be described as benzene-azo-phenol;  $C_6H_5(HSO_3).N_2.C_{10}H_7.OH$  is *p*-sulphobenzene-azo-( $\alpha$ )-naphthol, obtained by the action of diazotised-sulphanilic acid upon ( $\alpha$ )-naphthol; while  $C_6H_5.N_2.C_{10}H_7(HSO_3).OH$  is the isomeric benzene-azo-( $\alpha$ )-naphtholmonosulphonic acid obtained by the action of diazobenzene upon ( $\alpha$ )-naphtholmonosulphonic acid. The same rules may be followed with the more complicated types of azo-compounds; thus, for instance  $C_6H_5.N_2.C_6H_4.N_2.C_6H_4(OH)_2$ , benzeneazobenzene-azoresorcin obtained by the action of diazotised amidoazobenzene upon resorcin; in like manner  $C_6H_5.N_2.C_6H_4.N_2.C_{10}H_7(OH)_2$  may be called benzene-azotoluene-azoresorcin by the action of diazotised

benzene-azoamidotoluene upon resorcin; and  $C_6H_5.N_2.C_6H_4(OH)_2.N_2.C_6H_5$ , benzeneazodioxymethylenebenzene by the successive introduction of two diazobenzene-groups into resorcin. Secondary and tertiary azo-compounds of the types  $(R.N_2)_2.Pi'$ , and  $(R.N_2)_3.Pi''$  have been termed by Wallach *disazo-* and *trisazo-* compounds (B. 15, 22 and 2812; v. also Heumann, *ibid.* 813).

*Secondary and tertiary azo-compounds.*—The typical secondary azo-compound of the type  $(R.N_2)_2.Pi''$  is the so-called 'phenolbisdiazobenzene,'  $(C_6H_5.N_2)_2.C_6H_4.OH$ , discovered by Griess (B. 10, 628). Compounds of this class are formed by the successive introduction of two diazotised radicles into a phenol. The resorcin secondary azo-compounds have been especially studied by Wallach (B. 15, 22; Wallach & B. Fischer, *ibid.* 2814), and the cresol compounds by Nöling & Kohn (B. 17, 351). Analogous amido-compounds of the type  $(R.N_2)_2.C_6H_4(NH_2)_2$  have been obtained by the introduction of diazotised radicles into chrysoidine (Griess, B. 16, 2028). Secondary azo-compounds of the type  $R'(N_2.Pi)_2$  have been obtained by Wallach by acetylating one amido-group in a diamine, diazotising the acetamidio-compound, and combining with a phenol so as to produce a compound of the type  $R' < \begin{smallmatrix} N_2.Pi \\ NH.Ac \end{smallmatrix}$ . The acetyl group is then removed, the  $NH_2$ -group diazotised, and the diazo-compound  $R' < \begin{smallmatrix} N_2.Pi \\ N.Cl \end{smallmatrix}$  again combined with a phenol (B. 15, 2825 and Wallach & Schulze, *ibid.* 3020). The metadiamines appear to lend themselves most readily to this method. The most direct method of preparing secondary azo-compounds of this class is by diazotising both amido-groups in a *p*- or *m*-diamine, and then acting with the product upon a phenol or phenolsulphonic acid (Griess, B. 17, 607 and 19, 817). Another method of obtaining secondary azo-compounds of these types is by diazotising a *p*-nitramido-compound and combining with a phenol or secondary or tertiary amine so as to produce  $NO_2.R'.N_2.Pi$  or  $NO_2.R'.N_2.R''.NR_2$ . The nitro-group is then reduced, the amido-azo-compound diazotised and again combined with a phenol, &c., thus producing  $R''(N_2.Pi)_2$ ,  $R' < \begin{smallmatrix} N_2.R'' \\ N_2.Pi \end{smallmatrix}$ , &c. (Meldola, C. J. 43, 425; 45, 106 and 47, 657). If the nitro-azo-compound is combined with a monamine and the nitro-group reduced, a diamidoazo-compound of the type  $NH_2.R'.N_2.R''.NH_2$  is produced in which both amido-groups can be diazotised and combined with phenols so as to form tertiary azo-compounds,  $Pi.N_2.R'.N_2.R''.N_2.Pi$  (*ibid.*). Secondary azo-compounds of these types are also formed by reducing *p*-nitroacetanilide, diazotising and combining with a phenol or amine so as to produce azo-compounds of the type  $C_6H_5 < \begin{smallmatrix} NH.Ac \\ N_2.Pi \end{smallmatrix}$ . The acetyl group is then removed, the amido-azo-compound diazotised and again combined with a phenol (Nietzki, B. 17, 343 and 1350).

Secondary azo-compounds of the type  $R'.N_2.R''.N_2.Pi$  are obtained by diazotising amido-azo-compounds and combining the diazo-azo-salt with phenols. The typical compound,

$C_6H_5.N_2.C_6H_4.N_2.C_6H_4.OH$ , was first prepared by Caro and Schraube (B. 10, 2280) and several members of this group have since been introduced into commerce under the names of 'Biebrich scarlet,' 'Crocine scarlet,' &c. These scarlets are of considerable technical importance, especially the latter, which are prepared by the action of diazotised amidoazo-benzene-sulphonic acid and its homologues upon  $(\beta)$ -naphthol- $(\alpha)$ -sulphonic acid. By the action of diazotised amidoazobenzene upon chrysoidine a tertiary azo-compound of the type  $R'.N_2 > C_6H_4(NH_2)_2$  is formed (Griess, B.

16, 2036). Secondary azo-compounds of some importance have recently been prepared by diazotising diamidodiphenyl (benzidine) and its homologues and combining the tetrazo-salt with phenols, amines, and their sulphonic acids; of these colouring matters 'Congo red,'  $C_6H_5.N_2.C_6H_4(HSO_3NH_2)_2$ , may be mentioned as a typical example. Tertiary azo-compounds derived from triphenyl-carbinol are obtained by diazotising the rosanilines and combining with phenols (Meldola, C. J. 47, 668).

*Constitution of Azo-compounds.* When a diazo-compound combines with an amine or phenol to form an azo-compound the  $N_2$ -group invariably takes up the para-position with respect to the  $NH_2$ ,  $NH$ ,  $NR$ , or  $HO$ , if this position is open. The proof of the constitution of azo-compounds is furnished by the products which they yield on complete reduction. Thus, amidoazobenzene,  $C_6H_5.N_2.C_6H_4.NH_2$ , gives on reduction aniline and *p*-phenylene-diamine; chrysoidine gives aniline and (1, 2, 4)-triamidobenzene (Witt, B. 10, 658). The constitution of some of the azo-compounds obtained by combining diazosulphonic acids with phenols has been established by Griess (B. 11, 2191). The constitution of the azo-naphthol colours has been determined chiefly by Liebermann and his pupils (B. 14, 1310 and 1795; Jacobson, *ibid.* 1791; also Witt, C. J. 35, 179). When diazo-compounds act upon substituted phenols, such as salicylic acid, the  $N_2$ -group also takes up the para-position with respect to the  $HO$ -group (P. F. Frankland, C. J. 37, 746); thus  $(\alpha)$ -naphthaleneazosalicylic acid gives on reduction  $\alpha$ - $C_{10}H_7.NH_2$  and  $C_6H_5(HO)(NH_2)CO_2H$  [1:4:2]. When the para-position with respect to the  $NH_2$  or  $HO$ -group is already occupied the  $N_2$ -group enters the ortho-position (Nöling & Witt, B. 17, 77; Liebermann & Kostanecki, *ibid.* 130, 876; Griess, *ibid.* 338; Nöling & Kohn, *ibid.* 351). This law holds good also when the para-position is occupied by an azo-group, as in the formation of  $(C_6H_5.N_2)_2.C_6H_4.OH$  from benzeneazophenol by the introduction of another  $C_6H_5.N_2$ -group (Nöling & Kohn, B. 17, 368). In the case of the  $(\beta)$ -naphthalene derivatives the  $N_2$ -group also enters the ortho- $(\alpha)$ -position with respect to the hydroxyl or amido-group. Thus  $(\beta)$ -naphthol orange,  $HSO_3.C_6H_4.N_2.C_6H_4.OH$ , gives on reduction sulphanilic acid and  $(\alpha)$ -amido- $(\beta)$ -naphthol, the latter yielding  $(\beta)$ -naphthoquinone on oxidation (Liebermann, B. 14, 1310). Similarly the azo-derivatives of  $(\beta)$ -naphthylamine yield *o*-diamidonaphthalene ( $NH_2.NH_2 = \alpha$ ;  $\beta_2$ ) on reduction

(Lawson, *B.* 18, 796 and 2422). The fact that such compounds as benzeneazo-( $\beta$ )-naphthol are insoluble in cold aqueous alkalis has led Liebermann to the suggestion that these compounds no longer contain HO, but possess the formula  $C_6H_5.N \begin{smallmatrix} \diagup \\ \text{N} \\ \diagdown \end{smallmatrix} C_{10}H_7$  (*B.* 10, 2858). A similar conclusion has been suggested by Meldola with respect to the ( $\beta$ )-naphthylamine derivatives, for which he proposes the formula  $R.N \begin{smallmatrix} \diagup \\ \text{N} \\ \diagdown \end{smallmatrix} C_{10}H_7$ , thus indicating a relationship to the azimido-compounds above referred to (*C. J.* 45, 117). This conclusion is supported by the investigations of Zincke and his pupils (*B.* 18, 3125, 3132 and 3142). This author has shown that these ( $\beta$ )-naphthalene, as well as other ortho-amidoazo-compounds, can be oxidised to com-

pounds of the azimido-type,  $R.N \begin{smallmatrix} \diagup \\ \text{N} \\ \diagdown \end{smallmatrix} C_{10}H_7$ , and he suggests for them the alternative formula

$R.NH \begin{smallmatrix} \diagup \\ \text{N} \\ \diagdown \end{smallmatrix} C_{10}H_7$ . According to a recent paper by Nietzki a. Goll (*B.* 19, 1281) it appears, however, that amidonzo-( $\beta$ )-naphthalene contains an  $NH_2$ -group, or at any rate can be diazotised under certain conditions. There can be no doubt that the question of the constitution of the azo-compounds is much more complicated than was at first supposed, since by the action of diazo-compounds upon phenols two isomeric azo-compounds may be formed at the same time, the isomerism probably depending upon the position of the  $R.N_2$ -groups with respect to the HO as well as upon the formation of bodies of the oximido-type. This appears to be the case especially with the azo-derivatives of resorcinol (Wallach, *B.* 15, 22 and 2811).

**General properties and technology.**—The individual azo-colours will be described under their respective headings, so that it will be only necessary here to give a brief account of the general characters of these colouring matters. The parent azo-compounds,  $C_6H_5.N_2.C_6H_5$ ,  $C_6H_5.N_2.C_{10}H_7$ ,  $C_{10}H_7.N_2.C_{10}H_7$ , although possessed of colour are not of any value as dyestuffs; it is only when acid or basic radicles are present in one or both aromatic nuclei that true colouring matters are formed. The colours produced by these compounds are of various shades of yellow, orange, brown, red, scarlet, indigo-blue and violet. No pure blue or green azo-compound is known. Of the basic primary azo-compounds, amidazo-benzene, ehrysoidine, and 'phenylene brown,' show a gradation in shade from yellow through orange to brown. The two last compounds are now alone of technical value. Among the acid azo-colours a regular gradation of shade is also observed with the increase in molecular weight. This is well seen in the colours produced by the action of diazo-benzene and its homologues upon the naphthol-sulphonic acids, the lowest members of the series being orange, and the highest members scarlet of an increasing shade of blueness. The acid primary azo-compounds are dyed from acid baths and have great affinity for silk and wool, but do not readily dye cotton without the use of mordants. Primary azo-colours as a rule dia-

Vol. I.

solve in strong sulphuric acid with a red or orange colour. Azo-colours can be produced directly in the fibre of cotton by impregnating the latter with a phenol and a diazo-compound, and then developing by means of an acid (T. Holliday, *S. C. I.* 4, 204). A similar process has been described by Grüssler (*S. C. I.* 4, 262) who uses the nitrite in the form of an ammonium salt or in combination with ammonium salts, so that on heating the impregnated fabric the nitrous acid is liberated in the presence of the amine and phenol, and the colour is developed without the use of acid. Oxyazo-compounds, which are not sulphonic acids, and which are insoluble, can be made soluble by warming them in aqueous or alcoholic solutions of bisulphites. A soluble double compound is thus formed which is decomposed on heating with the liberation of the colouring matter so that the process is especially applicable for calico printing (Meister, Lucius a. Brüning, *B.* 17, 452). The secondary azo-colours derived from diazotised amidazo-benzene and its homologues in combination with naphtholsulphonic acids are scarlets of greater tinctorial power and purity than the primary azo-scarlets, and possess a certain affinity for cotton, especially the 'crocine scarlets' already referred to. The secondary azo-colours derived from diazotised benzidine ('Congo red' series) and its homologues are reds or yellows which also possess a certain affinity for cotton, but many of these colours are too sensitive to acids to be of much use technically. The stability of these colours is increased, however, by using the higher homologues of benzidine. It is only among secondary azo-compounds that true shades of violet and indigo blue are found (Nietzki, *B.* 17, 344; Meldola, *C. J.* 47, 665). Some of these blue shades are now met with in the market, a typical compound of the class being a salt of ditolyltetrazo-( $\beta$ )-naphtholdisulphonic acid,

$C_6H_5.N_2.C_{10}H_7.(HSO_3)(OH)\beta$  (Azo-blue of F. Bayer & Co.). Secondary azo-compounds dissolve as a rule in strong sulphuric acid with a violet, blue, or green colour. The tertiary azo-compounds have but little tinctorial value. For observations on the absorption spectra of azo-colours see papers by H. W. Vogel (*B.* 11, 623), Landauer (*B.* 14, 391), and Stebbins (*Am.* 6, 117 and 149).

R. M.

**AZO-COMPOUNDS.** (V. also AZO-COLOURING MATTERS and DI-AZO-COMPOUNDS.) The nomenclature of these compounds is based on the following rules. Imagine  $N_2$  displaced by  $H_2$  and the compound to break up accordingly, one H going to one half and one to the other. If both the resulting compounds are aromatic, name the compound richest in carbon according to the rules followed in this dictionary, and prefix azo- to the name. Before azo- write the name of the hydrocarbon from which the other half of the molecule is derived. Then prefix all the substituents of the latter so that they may follow one another in this order: chloro-, bromo-, iodo-, cyano-, nitro-, oxy-, amido-, sulphy-, and carboxy-. When both halves of the azo-compound contain the same number of atoms of carbon, then the half which contains  $CO_2H$  is put last. If neither contain  $CO_2H$ , the one containing

B B

$\text{SO}_2\text{H}$  comes last; if neither contain this, preference is given to  $\text{OH}$ ,  $\text{NH}_2$ ,  $\text{NO}_2$ ,  $\text{Br}$ , or  $\text{Cl}$ , in succession.

If one half of an azo-compound is derived from a fatty hydrocarbon the name of this half is written last.

The compounds obtained by the action of diazo-compounds upon ( $\beta$ )-naphthylamine, ( $\beta$ )-naphthol, or more generally upon amido- or oxy-compounds in which the  $p$ -position is already occupied, are described as if they were ordinary azo-compounds. It is, however, not improbable that they may have a different constitution. Thus the compounds obtained from diazo-compounds and ( $\beta$ )-naphthylamine behave like diazoamides in their decomposition by acids into ( $\beta$ )-naphthylamine, a phenol, and nitrogen; but act on reduction like amido-azo-derivatives giving (1,2)-naphthylene-diamine and the amine. Three views may be taken with regard to the constitution of these bodies:—(1) That they are true diazoamides; (2) that they are  $o$ -amido-azo-derivatives; (3) that they are hydrazimido-compounds, *i.e.* dihydrides of azimido-compounds.

The first hypothesis easily explains their decomposition by acids; and their reduction to naphthylene-diamine might be accounted for by assuming an intermediate change into the amido-azo-compound. However, the fact that a different isomeric body is formed by diazotising ( $\beta$ )-naphthylamine and combining it with the other amine does not agree with this view, since compounds of the form  $\text{X.N}_2\text{.NHY}$  and  $\text{Y.N}_2\text{.NHX}$  are always found to be identical. The other reactions of these bodies are also inconsistent with this hypothesis. The hypothesis that the compounds are  $o$ -amido-azo-derivatives does not readily account for their behaviour on oxidation, which tends to show that they do not contain an  $\text{NH}_2$  group.

The third hypothesis leads to the formula

It is strongly supported by the fact that on oxidation these bodies give rise to white crystalline azimido-compounds, which probably have

the constitution  $\text{C}_{10}\text{H}_7\begin{array}{c} \text{N} \\ \diagup \quad \diagdown \\ \text{N} \end{array} \text{NR}$ , analogous to

Griess's azimidobenzene  $\text{C}_6\text{H}_5\begin{array}{c} \text{N} \\ \diagup \quad \diagdown \\ \text{N} \end{array} \text{NH}$  obtained

by the action of nitrous acid on  $o$ -phenylenediamine. The corresponding compounds from ( $\beta$ )-naphthol and diazo-salts may also be obtained by the action of hydrazines upon ( $\beta$ )-naphthoquinone, and hence may be represented in a similar manner by the formulae

The formation of hydrazimido-compounds from a diazo-salt and ( $\beta$ )-naphthylamine can be explained by assuming the intermediate formation of true diazo-amides  $\text{C}_{10}\text{H}_7\text{.NH.N.NR}$ , which by taking up  $\text{H}_2\text{O}$  (or  $\text{HCl}$ ) would form  $\text{C}_{10}\text{H}_7\text{.NH.N(OH).NHR}$  or  $\text{C}_{10}\text{H}_7\text{.NH.NH.N(OH).NR}$ , and by again eliminating  $\text{H}_2\text{O}$  it might give the salt with hydrazimido-compound. The decomposition by

acids might also be explained as a change inverse to the above, resulting in the formation of the diazo-amide, which would then be decomposed. The *ortho*-amido-azo-derivatives of the benzene series would also seem to be similarly constituted, for on oxidation they also give colourless crystalline azimido-compounds.

Apparently opposed to the hydrazimido-hypothesis, is the behaviour of these bodies towards nitrous acid, which converts them into diazo-compounds. In many points, however, these diazo-compounds greatly differ from the ordinary diazo-compounds, and their constitution may possibly be expressed by the formula:

$\text{R}'\begin{array}{c} \text{N-NH} \\ \diagup \quad \diagdown \\ \text{N-N.R}' \end{array}$ . The  $o$ -diazo-imides readily lose  $\text{N}_2$  on heating and are converted into azimido-

compounds  $\text{R}'\begin{array}{c} \text{N} \\ \diagup \quad \diagdown \\ \text{N} \end{array} \text{N.R}'$  identical with those

obtained by oxidation of the  $o$ -amido-azo-compounds. On the hydrazimido-hypothesis the body derived from diazo-benzene and phenyl- ( $\beta$ )-naphthylamine would be represented by the

formula  $\text{C}_{10}\text{H}_7\begin{array}{c} \text{N.C}_6\text{H}_5 \\ \diagup \quad \diagdown \\ \text{N.HC}_6\text{H}_5 \end{array}$ , which agrees with its

reactions. Thus conc.  $\text{HCl}$  removes aniline, forming an azine  $\text{C}_{10}\text{H}_7\begin{array}{c} \text{N} \\ \diagup \quad \diagdown \\ \text{N} \end{array} \text{C}_6\text{H}_5$ , while oxi-

dising agents produce a powerful ammonium base  $\text{C}_{10}\text{H}_7\text{N}_4(\text{C}_6\text{H}_5)_2\text{OH}$  (Meldola, *C. J.* 45, 107; Nötling a. Wilt, *B.* 17, 77; Lawson, *B.* 18, 796, 2122; Sachs, *B.* 18, 3125; Zincke, *B.* 18, 3132, 3142; Zincke a. Lawson, *B.* 19, 1452).

#### DESCRIPTION OF AZO-COMPOUNDS.

**Acetophenone-azo-( $\beta$ )-naphthol** [4:1]  $\text{C}_6\text{H}_5(\text{CO.CH}_3) \cdot \text{N}_2 \cdot \text{C}_{10}\text{H}_7(\text{OH})$ . Formed by diazotising  $p$ -amido-acetophenone and combining the diazo-compound with ( $\beta$ )-naphthol in alkaline solution (Klingel, *B.* 18, 2695). Slender red needles. V. sol. alcohol, sl. sol. ether, insol. water. Dyes silk a dull red.

**$o$ -Amido-benzene-azo-aceto-acetic acid**  $\text{C}_6\text{H}_4(\text{NH}_2) \cdot \text{N}_2 \cdot \text{CH}(\text{CO.CH}_3) \cdot \text{CO}_2\text{H}$ . [157°]. Orange-red tables. Easily soluble in acetic acid, alcohol, ether and chloroform, sparingly in water. Formed by reduction of  $o$ -nitro-benzene-azo-aceto-acetic acid with  $\text{FeSO}_4$  and  $\text{NH}_4$  (Bamberger, *B.* 17, 2420).

**$p$ -Amido-benzene- $p$ -azo-aniline**  $\text{C}_6\text{H}_4(\text{NH}_2) \cdot \text{N}_2 \cdot \text{C}_6\text{H}_4(\text{NH}_2)$ . *p*-Azo-aniline. *Di-amido-azo-benzene*. [235°]. Long flat yellow needles. Easily soluble in alcohol, sparingly in benzene and ligroine.

**Preparation.**—1. The mono-acetyl derivative of  $p$ -phenylene-diamine is diazotised and combined with aniline, the aniline thus obtained is dissolved in aniline and warmed with aniline hydrochloride by which it is converted into the mono-acetyl derivative of amido-benzene-azo-

aniline, which is finally saponified.—2. From its di-acetyl derivative which is formed by the action of zinc and ammonia on acetyl-*p*-nitro-aniline (Mixer, *Am.* 5, 282).

The mono-acid salts are green, the di-acid red.  $B''H_2Cl_2$ : needles.

*Mono-acetyl derivative*  $C_{12}H_9N_2(NH_2)(NHAc)$ . [212°], glistening golden yellow plates. Its salts are red (Nietzki, *B.* 17, 345).

*Di-acetyl derivative* [282°] (M.).

**Amido-benzene-azo-aniline**

[4:1]  $C_6H_4(NH_2)-N_2-C_6H_4NH_2$  [1:4]. [142°]. Obtained by reducing nitro-benzene-azo-nitro-benzene [206°] with alcoholic ammonium sulphide (Janovsky, *M.* 6, 460). Minute plates (from alcohol). Salt.— $B''H_2Cl_2$ . This body is probably identical with the preceding, the melting-point having perhaps been misprinted.

*m*-Amido-benzene-*m*-azo-aniline

[3:1]  $C_6H_4(NH_2)-N_2-C_6H_4(NH_2)$  [1:3]. From the nitro-compound by ammonium sulphide (Janovsky, *M.* 6, 458). Minute flat yellow needles with green lustre (from alcohol).

**Amido-benzene-azo-benzene-*p*-sulphonic acid** [4:1]  $C_6H_4(HSO_3)-N:N-C_6H_4NH_2$  [1:4] S. 0144 at 22°. Yellowish-white microscopic needles or scales (containing aq). Nearly insoluble in water, alcohol, ether, and chloroform. Formed by the action of diazo-benzene-*p*-sulphonic acid on aniline (to extent of about 30 p.c.). Prepared from benzene-azo-aniline and fuming  $H_2SO_4$  at about 70°. On reduction with tin and HCl it gives *p*-phenylene-diamine and sulphamic acid.

**Salts.**— $ANH^+$ : orange-yellow plates.— $A'Ba$ aq: sparingly soluble trimetric orange needles.— $A'Ca$  2aq (Griess, *B.* 15, 2184).

**Amido-benzene-azo-benzene-*p*-sulphonic acid** [4:1]  $C_6H_4(SO_3H)-N:N-C_6H_4NH_2$  [1:4]. S. 0196 at 22°. Pearly plates (containing aq). Formed by reduction of the sparingly soluble nitro-benzene-azo-benzene-*p*-sulphonic acid with ammonium sulphide. On complete reduction with tin and HCl it gives *p*-sulphanilic acid and *p*-phenylene-diamine, and hence ought, according to theory, to be identical with the preceding compound; this, however, does not appear to be the case.

**Salts.**— $KA$ aq: yellow trimetric plates.— $NaA'$ : needles.— $BaA'$  6aq: large glistening monoclinic needles.— $CaA'$  4aq: yellow pearly plates.— $PbA'$ : monoclinic plates (Janovsky, *B.* 16, 1488; *M.* 4, 279, 652).

**Di-amido-benzene-azo-benzene-*p*-sulphonic acid**  $(NH_2)_2C_6H_3-N_2-C_6H_4SO_3H$ . *Chrysoidine sulphonic acid*. Brownish-red glistening needles. Sl. sol. water.

**Formation.**—1. By combination of *p*-diazo-benzene-sulphonic acid with *m*-phenylene-diamine.—2. By sulphonation of chrysoidine. On reduction it gives sulphanilic acid and (1:2:4)-tri-amido-benzene (Griess, *B.* 15, 2196).

***m*-Amido-benzene-*p*-azo-di-methyl-aniline**

[3:1]  $C_6H_4(NH_2)-N_2-C_6H_4NMe_2$  [1:4]. [166°]. Golden laminae, sol. alcohol. Formed by the action of warm dilute  $H_2SO_4$  on its acetyl derivative [184°] which is obtained by mixing diazotised acetyl-*m*-tolylene-diamine with dimethyl-aniline (Wallach, *A.* 234, 263).

***p*-Amido-benzene-azo-dimethylaniline**

[4:1]  $NH_2.C_6H_4.N_2.C_6H_4.NMe_2$  [1:4]. [188°]. By

warming the alcoholic solution of the nitro-compound  $NO_2.C_6H_4.N_2.C_6H_4.NMe_2$  with ammonium sulphide (Meldola, *C. J.* 45, 107).

**Properties.**—Brick-red needles (from dilute alcohol). Insol. boiling water, but forms yellow solutions in most solvents. Reduced by zinc dust and HCl it gives dimethyl-*p*-phenylene-diamine and *p*-phenylene-diamine. On adding acetic acid to an alcoholic solution, the liquid turns green, on dilution with water it becomes red. In conc.  $H_2SO_4$  the solution is orange. A very dilute solution mixed with nitrous acid and exposed to the air turns blue (test for nitrous acid).— $B''(HCl)_2PtCl_6$ .

*Methylo-iodide.*—Insoluble brown scales.

*Acetyl derivative.*—Orange needles (from alcohol). [217°].

***p*-Amido-benzene-azo-( $\beta$ )-naphthol**

[4:1]  $NH_2.C_6H_4.N:N.C_{10}H_7.OH$  [ $\alpha:\beta$ ]. Formed by reducing the corresponding nitro-compound with ammonium sulphide and ammonia. Forms a crimson solution in  $H_2SO_4$  (Meldola, *C. J.* 47, 668).

***p*-Amido-benzene-azo-( $\alpha$ )-naphthol**

[4:1]  $NH_2.C_6H_4.N:N.C_{10}H_7.OH$  [ $\alpha:\beta$ ]. Formed by reducing para-nitro-benzene-azo-( $\alpha$ )-naphthol in hot dilute NaOH with ammonium sulphide; ppd. by HCl (Meldola, *C. J.* 47, 662). Dark brown powder; sl. sol. hot water, v. sol. hot alcohol. Forms a red solution in conc.  $H_2SO_4$ .

***p*-Amido-benzene-azo-( $\beta$ )-naphthol di-sulphonic acid.** *Acetyl derivative*

$C_{14}H_{11}(NHAc)-N_2-C_{10}H_6(OH)(SO_3H)_2$ . Golden glistening plates. Scarlet red dye-stuff. Formed by diazotising the mono-acetyl derivative of *p*-phenylene-diamine and combining it with ( $\beta$ )-naphthol (R)-di-sulphonic acid (modification insoluble in alcohol). By saponification of the acetyl group it yields a bordeaux-red dye stuff. By diazotising the latter and combining it with ( $\beta$ )-naphthol di-sulphonic acid a blue colouring matter is produced (Nietzki, *B.* 17, 344).

***p*-Amido-benzene-azo-( $\alpha$ )-naphthylamine**

[4:1]  $NH_2.C_6H_4.N:N.C_{10}H_7NH_2$  [1:4]. [160°]. Formed by reducing  $NO_2.C_6H_4.N_2.C_{10}H_7NH_2$  with aqueous ammoniac sulphide (Meldola, *C. J.* 43, 432). Ochreous needles. Readily soluble in alcohol, acetone, benzene and chloroform. Its salts form crimson aqueous solutions; excess of acid throws down the neutral salts.— $B''(HCl)_2PtCl_6$ .

***p*-Amido-benzene-azo-o-oxy-benzoic acid**

[4:1]  $NH_2.C_6H_4-N_2-C_6H_3(OH)(CO_2H)$  [1:4:2]. From the sodium salt of *p*-nitro-benzene-azo-salicylic acid by reduction with ammonium sulphide. Colourless needles. Sl. sol. boiling water. Its alkaline solutions are yellow. Glacial HOAc forms a crimson solution. Blackens at 219°–220° C. (Meldola, *C. J.* 47, 667).

***m*-Amido-benzene-azo-phenol**

[3:1]  $C_6H_4(NH_2)-N_2-C_6H_4.OH$  [1:4]. [168°]. Brownish yellow scales. Obtained by saponification of the acetyl derivative.

*Acetyl derivative*

$C_{12}H_9(NHAc).N_2.C_6H_4.OH$  [c. 208°]. Prepared by diazotising the mono-acetyl derivative of *m*-phenylene-diamine and combining it with phenol (Wallach, *B.* 15, 3020).

***p*-Amido-benzene-azo-phenol**

[4:1]  $NH_2.C_6H_4.N:N.C_6H_4.OH$  [1:4]. [181°]. Obtained by heating *p*-nitro-benzene-azo-phenol with ammonium sulphide. Brown scales (from

water); v. sol. alcohol.— $B''H_2PtCl_6$  (Meldola, *C. J.* 47, 658).

**p-Amido-benzene-azo-diphenylamine**

[4:1]  $NH_2.C_6H_4.N_2.C_6H_5.NHC_6H_5$  [1:4] [c. 91°]. Got by reducing the nitro-compound by ammoniac sulphide (Meldola, *C. J.* 43, 440).

*Properties*.—Sl. sol. in boiling water, v. sol. alcohol, acetone, chloroform and benzene, forming yellow solutions. HCl added to the alcoholic solution turns it first green, then red. Solution in conc.  $H_2SO_4$  is violet, turned red by diluting.

*Salts*.—Form crimson aqueous solutions. Dye wool orange.

**m-Amido-benzene-azo-m-phenylene-diamine**

[8:1]  $C_6H_4(NH_2)-N_2-C_6H_4(NH_2)_2$  [1:2:4]. *Bismarck brown*. [137°]. Ppd. by adding  $NaNO_2$  to a neutral solution of m-phenylene-diamine hydrochloride (Caro a. Griess, *Z.* 1867, 278). Brown plates. Sl. sol. in hot water; v. e. sol. alcohol and ether. Dyes wool brown. Absorption spectrum (Hartley, *C. J.* 51, 180).

*Salts*.— $B''^2HCl$ .— $B''^2H_2PtCl_6$ .

**p-Amido-benzene-azo-phenylene-diamine**

\*[4:1]  $C_6H_4(NH_2)-N_2-C_6H_4(NH_2)_2$  [1:2 or 3:4]. From benzene-azo-benzene by nitration and reduction (Janovsky, *M.* 6, 466).

**p-Amido-benzene-azo-resorcin**

[4:1]  $NH_2.C_6H_4.N_2.N.C_6H_3(OH)_2$  [1:2:4]. By dissolving p-nitro-benzene-azo-resorcin in dilute  $NaHO$  and warming with ammonium sulphide (Meldola, *C. J.* 47, 661). Its alkaline solutions are red; its acid solutions are pale orange.— $B''_2H_2SO_4$ : silvery scales.— $B''^2H_2PtCl_6$ .

**p-Amido-benzene-azo-m-xylidine**

[4:1]  $NH_2.C_6H_4.N_2.C_6H_4Me.NH_2$  [1:3:5:2] [163°]. Formed by reducing  $NO_2.C_6H_4.N_2.C_6H_4Me.NH_2$  with aqueous ammoniac sulphide (Meldola, *C. J.* 43, 432). Golden scales (from water). V. sol. alcohol and benzene.

*Salts*.—The acid salts are very soluble in water. Excess of HCl forms an amorphous brown pp. of  $B''^2HCl$ .—( $B''^2HCl$ ) $PtCl_6$ .

**Amido-thiophene-azo-benzene**

$C_6H_4.N_2.C_6SH_2.NH_2$ . Formed by adding diazo-benzene chloride to a tolerably concentrated solution of thiophenine hydrochloride.— $H^2HCl$  aq: yellow needles, soluble in water and alcohol (Stadler, *B.* 18, 2317).

**Amido-thiophene-azo-benzene-p-sulphonic acid** [4:1]  $C_6H_4(SO_3H).N_2.C_6SH_2.NH_2$ . Formed by combination of diazo-benzene-p-sulphonic acid with thiophenine. Yellow needles, red when dry. Sl. sol. water and alcohol. Dyes silk yellow. (Stadler, *B.* 18, 2318).

**Amido-thiophene-azo-naphthalene**

$C_6H_4.N_2.C_6SH_2.NH_2$ . Formed by adding (a)-diazo-naphthalene chloride to a solution of thiophenine hydrochloride. The hydrochloride forms microscopic red needles, sparingly soluble in water and alcohol (Stadler, *B.* 18, 2318).

**m-Amido-toluene-azo-aceto-acetic acid**

[4:2:1]  $C_6H_4(CH_3)(NH_2).N_2.CH(CO.CH_3).CO_2H$  [162°]. Red glistening needles. Formed by reduction of m-nitro-toluene-azo-aceto-acetic acid with  $FeSO_4$  and  $NH_4$  (Bamberger, *B.* 17, 2421).

**Amido-toluene-azo-amido-cresol**

[4:3:1]  $C_6H_3(CH_3)(NH_2).N_2.C_6H_3(CH_3)(OH)$ . *Oryazo-toluidine* [212°]. Small dark-red needles. V. sol. alcohol and ether, sl. sol. water. Formed from amido-toluene-azoxy-toluidine

$C_6H_3Me(NH_2).N_2.O.C_6H_3Me(NH_2)$  by intramolecular change by heating it with  $H_2SO_4$  at 110°. It is reduced by  $SnCl_2$  to tolylene-diamine  $C_6H_3Me(NH_2)_2$  [1:2:4] together with di-amido-cresol (Limpricht, *B.* 18, 1406).— $B''^2H_2SO_4$ .— $B''^2HCl$ .— $B''^2H_2PtCl_6$ .

**Amido-toluene-azo-(β)-naphthol**

[6:3:1]  $C_6H_3(CH_3)(NH_2)-N_2-C_{10}H_7OH$  [1:2].

**Acetyl derivative**

$C_6H_3(CH_3)(NHAc)-N_2-C_{10}H_7OH$  [276°]. Insol. water, sl. sol. alcohol, m. sol. a mixture of alcohol and chloroform. Red colour. Formed by diazotising the mono-acetyl derivative of (1:2:4)-tolylene-diamine and combining it with (β)-naphthol (Wallach, *B.* 15, 2830).

**Amido-toluene-azo-nitro-ethane.**

*Acetyl derivative*  $C_6H_3Me.N_2O_2$ , i.e.

[6:3:1]  $C_6H_3Me(NHAc).N_2.CH(NO_2).CH_3$ . [143°]. From  $C_6H_3Me(NHAc).N_2.Br$  and  $NaCH(NO_2)CH_3$  (Wallach, *A.* 235, 250). Red needles (from alcohol-ether); v. sl. sol. water, insol. ligroin.

**Amido-toluene-azo-o-toluidine**

[4:3:1]  $C_6H_3Me(NH_2)-N_2-C_6H_3Me(NH_2)$  [1:4:3] [197°]. Formed by reducing nitro-o-toluidine  $C_6H_3Me(NO_2)(NH_2)$  [1:4:2], or the corresponding azoxy-compound, by sodium amalgam in alcoholic solution (Limpricht, *B.* 18, 1406; Graeff, *A.* 229, 350). Long red needles (from alcohol) or small yellow needles (from water). Sparingly soluble in water, easily in alcohol and ether.

*Salts*.— $B''^2H_2SO_4$ : Slender reddish needles.— $B''^2HCl$ .—( $B''^2HCl$ ) $PtCl_6$ .— $B''^2HBr$ .

**Amido-toluene-azo-p-toluidine**

[6:3:1]  $C_6H_3Me(NH_2)-N_2-C_6H_3Me(NH_2)$  [1:6:3]. [159°]. Red needles. Sl. sol. cold, v. sol. hot, water; v. sol. alcohol. Prepared together with the hydrazo-compound by the prolonged action of sodium amalgam on an alcoholic solution of nitro-p-toluidine (Buckney, *B.* 11, 1453).

**Di-amyli-amido-benzene-azo-di-amyli-aniline**

[4:1]  $(C_6H_4)_2N_2.C_6H_4-N_2-C_6H_4N(C_6H_4)_2$  [1:4]. *Di-amyli-aniline-azylinc*. [115°]. Red pointed crystals. Sol. hot alcohol. Formed by passing  $NO$  through an alcoholic solution of di-amyli-aniline. *Salts*.— $B''(C_6H_4(NO_2)_2OH)_2$ : small yellow crystals. Periodic  $B''^2I_4$ : small black crystals with violet reflex (Lippmann a. Fleissner, *B.* 15, 2142 and *B.* 16, 1419).

**Benzene-azo-aceto-acetic acid**

$C_6H_5-N_2-CHAc.CO_2H$ . [155°]. Yellow leaflets (from alcohol). Prepared by the action of a solution of diazobenzene nitrate on an alkaline solution of acetoacetic ether (V. Meyer, *B.* 10, 2076).

*Salts*.— $A'K$ : yellow glistening leaflets.— $BaA'$ ,  $PbA'$ ,  $CuA'$ , and  $AgA'$  are yellow pps. *Ethylether* [75°]. Light yellow crystals; very readily saponified (Züblin, *B.* 11, 1417).

**Benzene-azo-acetone**

$C_6H_5.N_2.CH_2.CO.CH_3$ . [149°]. Glistening yellow prisms or needles. Peculiar characteristic smell. Only slightly soluble in hot water, and in aqueous alkalis.

*Formation*.—1. By heating benzene-azo-aceto-acetic ether with a dilute alcoholic solution of  $NaOH$ .—2. By heating benzene-azo-aceto-acetic acid to 170°–180°,  $CO_2$  being evolved (Richter a. Münzer, *B.* 17, 1928).

**Benzene-azo-acetophenone**

$C_6H_5.N_2.CH_2.CO.C_6H_5$ . [129°]. Slender golden needles. V. sol. hot alcohol and hot acetic acid. Formed, together with benzene-azo-benzoyl-acetic ether, by adding a solution of diazo-

benzene chloride to an ice alkaline solution of benzoyl-acetic ether (Bamberger a. Calman, *B.* 18, 2568).

**Benzene-o-azo-aniline (?)**.

$C_6H_5-N_2-C_6H_4NH_2$  (?). [123°]. Formed by reducing benzene-o-azo-nitro-benzene with ammonium sulphide (Janovsky, *M.* 8, 61; yellow crystals with blue reflex (from dilute alcohol). The salts are less soluble in water than those of the *p*-compound.

**Benzene-azo-aniline**  $C_{12}H_{11}N_3$ , i.e.

$C_6H_5-N_2-C_6H_4NH_2$  [1:4]. *Anido-azo-benzene*. Mol. w. 197. [126°]. (above 360°).

**Formation.**—1. By reducing benzene-azo-nitro-benzene [137°] with ammonium sulphide (G. Schmidt, *Z.* 5, 417; Janovsky a. Erb, *B.* 18, 1136).—2. Together with bromo-aniline by the action of bromine vapour upon aniline (Kekulé, *Z.* [2] 1, 688).—3. By action of mineral acid (one molecule or less) upon diazo-benzene anilide (v. Di-azo-compounds) (Martius a. Griess, *Z.* [2] 1, 132; Friswell a. Green, *C. J.* 49, 746).

**Preparation.**—1. Diazo-benzene-anilide is dissolved in 2 or 3 times its weight of aniline,  $\frac{1}{10}$ th its weight of aniline hydrochloride is added at the ordinary temperature, and the mixture is kept for an hour at 30° to 40°; after standing for twenty-four hours at the ordinary temperature, sufficient HCl is added to combine with the free aniline and the amido-azo-benzene base precipitates, or it can be obtained as hydrochloride by adding more HCl. The yield is nearly theoretical (Witt a. Thomas, *C. J.* 43, 113; Staedel a. Bauer, *B.* 19, 1953).—2. A conc. solution (of rather less than 1 mol.) of NaNO<sub>2</sub> is added to (1 mol. of) aniline hydrochloride dissolved in (5 or 6 mols. of) aniline at 30°–40°, kept at c. 40° for 1 or 2 hours, and then at the ordinary temperature for 12 hours; completed as above, the yield is nearly theoretical.

**Properties.**—Yellow crystals; separates from benzene with benzene of crystallisation (W. a. T.); orange prisms with blue reflex (from alcohol). V. sl. sol. hot water, m. sol. ether and alcohol. Its salts are decomposed by water; they dye wool yellow. Tin and HCl give aniline and *p*-phenylene-diamine. Combines with EtI forming the hydriodide of  $C_6H_4(NH_2).N_2C_6H_4NH_2Et$ . The diazo-compounds of benzene-azo-aniline and its sulphonic acids are used for the preparation of scarlets by combination with the naphthols and their sulphonic acids.

**Salts.**—B'HCl: steel-blue needles or scales (from boiling HClAq).—B'<sub>2</sub>H<sub>2</sub>PtCl<sub>6</sub>.—B'HNO<sub>2</sub>.—B'<sub>2</sub>H<sub>2</sub>SO<sub>4</sub>.—B'<sub>2</sub>H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>.

**Acetyl derivative**  $C_{12}H_{11}N_3C_2H_3(NHAc)$ . [142°]. Yellow silky crystals. On reduction with alcoholic ammonium sulphide it gives acetyl-amido-hydrazobenzene (Schultz, *B.* 17, 463; Berju, *B.* 17, 1400; C. C. 1884, 871).

**Reactions.**—1. By boiling benzene-azo-aniline with 10 pts. of HCl (S.G. 1.12) it is completely decomposed in a few hours with formation of *p*-phenylene-diamine, aniline, chlorinated-hydroquinones, NH<sub>3</sub>, and colouring matters (Wallach a. Kölliker, *B.* 17, 395).—2. An alcoholic solution of bromine forms a dibromo-derivative [152°] which is reduced by tin and HCl to aniline and *p*-phenylene-diamine (Berju, *B.* 17, 1400).—3. With phenyl thio-carbimide

it forms benzene-azo-di-phenyl-thio-urea (*q. v.*), together with some benzene-azo-di-phenyl-thio-urea-azo-benzene (v. di-azo compounds).—4. Carbonyl chloride forms benzene-azo-di-phenyl-urea-azo-benzene (Ph—N<sub>2</sub>—C<sub>6</sub>H<sub>4</sub>.NH).CO (Berju, *B.* 17, 1404).—5. Benzene-azo-aniline hydrochloride (2 mols.) heated with acetone (1 mol.) at 150°–160° under pressure forms a base  $C_{12}H_{11}N_3$ . [205°]. Yellow needles; v. sol. alcohol, ether, and acids. By tin and HCl it is reduced to a base of melting-point [185°]. Dilute solutions of the salts have a blue fluorescence. Salts.—B'H<sub>2</sub>SO<sub>4</sub>: slender soluble needles or small monoclinic prisms.—B'H.Cr<sub>2</sub>O<sub>7</sub>: orange-yellow needles.—B'H.Cl<sub>2</sub>PtCl<sub>6</sub>: flat yellow needles, sl. sol. cold water (Engler a. Schestopal, *B.* 20, 180).

**Benzene-azo-benzene**  $C_{12}H_{10}N_2$ , i.e.  $C_6H_5-N_2-C_6H_5$ . *Azobenzene*. Mol. w. 182. [68°]. [293°]. V.D. 6.5 (calc. 6.3). S. (alcohol) 8.5 at 16° (Moltehanoffsky, *J. R.* 1882, 224). S.V. 220.4 (Ramsay).

**Formation.**—1. By treating nitro-benzene with alcoholic potash (Mitscherlich, *A.* 12, 311; Schmidt a. Schultz, *A.* 207, 328), sodium-amalgam in presence of alcohol and acetic acid (Verigo, *A.* 135, 176; Alexejoff, *Z.* [2] 3, 33), iron (3 pts.) and acetic acid (1 pt.) (Noble, *A.* 98, 253), or with zinc-dust (Alexejoff, *Bl.* [2] 34, 684).—2. By oxidising aniline with aqueous KMnO<sub>4</sub> (Glaser, *A.* 142, 364), red-hot PbO (Schichuzky, *J. R.* 6, 245), H<sub>2</sub>O<sub>2</sub> (Leeds, *C. N.* 41, 210; *B.* 14, 1382) or bleaching powder (Schmitt, *J. pr.* [2] 18, 195).—3. It is the chief product of the action of sodium on *p*-bromo-aniline (Anschütz a. Schultz, *B.* 9, 1398; cf. Claus, *B.* 15, 315).

**Preparation.**—1. By heating nitro-benzene with a solution of sodium stannite prepared by dissolving the theoretical quantity of SnCl<sub>2</sub> in an excess of aqueous NaOH (Witt, *B.* 18, 2912).—2. 400 grms. of NaOH (98 p.c. powdered) are boiled with 2000 c.c. of ordinary alcohol till most has dissolved; 500 g. of nitrobenzene are slowly added to the boiling solution, and the formation of azoxybenzene completed by 2 or 3 hours' cohobation. 200 grms. of zinc-dust are then slowly added and the boiling continued for a day with occasional shaking. The alcohol is distilled off on a salt bath, warm water added, the insoluble portion filtered off, washed, freed from Zn(OH)<sub>2</sub> by HCl, and extracted with alcohol; the filtrate on cooling deposits the azo-benzene in splendid large plates; good yield.

**Properties.**—Trimetric plates (Jeremejeff). Crystallises with C<sub>6</sub>H<sub>6</sub> from benzene. Its absorption-spectrum has been described by Hartley (*C. J.* 51, 176).

**Reactions.**—1. Passed through a red-hot tube it yields benzene and diphenyl (Ferro, *B.* 20, 664).—2. Chromic acid in acetic acid at 200° forms benzene-azoxy-benzene.—3. Nitric acid forms Ph.N<sub>2</sub>.C<sub>6</sub>H<sub>4</sub>(NO<sub>2</sub>) [1:4], Ph.N<sub>2</sub>.C<sub>6</sub>H<sub>4</sub>(NO<sub>2</sub>) [1:2], [4:1] C<sub>6</sub>H<sub>4</sub>(NO<sub>2</sub>).N<sub>2</sub>.C<sub>6</sub>H<sub>4</sub>(NO<sub>2</sub>) [1:4], [1:3] C<sub>6</sub>H<sub>4</sub>(NO<sub>2</sub>).N<sub>2</sub>.C<sub>6</sub>H<sub>4</sub>(NO<sub>2</sub>) [1:3], and a nitro-benzene-azo-di-nitro-benzene.—4. Alcoholic ammonium sulphide reduces it to hydrazobenzene (Hofmann, *Pr.* 12, 576).—5. Hot conc. HCl, HBr, or HI reduces it to benzidine, other products being formed at the same time.—6. Alcoholic SO<sub>2</sub> produces benzidine.—7. With an ethereal solution of zinc ethyl it reacts forming ethane (1 vol.), ethylene (3 vols.), and a

latter body is not formed, however, by heating the hydrazo-compound, previously prepared, with HCl, but benzene-azo-chloro-benzene, chloro-aniline, and aniline are formed instead. On nitration with fuming HNO<sub>3</sub>, benzene-azo-chloro-benzene gives *p*-chloro-benzene-azo-*p*-nitro-benzene C<sub>6</sub>H<sub>4</sub>Cl.N<sub>2</sub>.C<sub>6</sub>H<sub>3</sub>(NO<sub>2</sub>). By treatment with fuming sulphuric acid it is converted into *p*-chloro-benzene-azo-benzene *p*-sulphonic acid C<sub>6</sub>H<sub>4</sub>Cl.N<sub>2</sub>.C<sub>6</sub>H<sub>4</sub>(SO<sub>3</sub>H) (Mentha a. Heumann, B. 19, 2970).

**Benzene-azo-o-cresol**  
C<sub>6</sub>H<sub>5</sub>-N<sub>2</sub>-C<sub>6</sub>H<sub>3</sub>(CH<sub>3</sub>)(OH) [1:3:4]. [130°]. Glistening yellow plates. V. sol. alcohol, ether, chloroform, and benzene; sl. sol. hot, insol. cold, water. Dissolves in dilute alkalis with a yellowish red colour. Obtained by the action of diazobenzene chloride on an alkaline solution of *o*-cresol. It readily gives a dis-azo-compound when treated in alkaline solution with a further quantity of diazobenzene chloride.

*Acetyl derivative*: [82°]; yellow tables, v. sol. alcohol, ether, and benzene.

*Benzoyl derivative*: [111°]; small yellow needles, v. sol. ether, acetone, and hot alcohol (Liebermann a. Kostanecki, B. 17, 130; Nöling a. Kohn, B. 17, 363).

**Benzene-azo-m-cresol**  
C<sub>6</sub>H<sub>5</sub>-N<sub>2</sub>-C<sub>6</sub>H<sub>3</sub>(CH<sub>3</sub>)(OH) [1:2:4]. [109°]. Yellow needles. V. sol. alcohol, ether, chloroform and benzene. With alkalis it forms yellowish-red salts. Obtained by the action of diazobenzene chloride on an alkaline solution of *m*-cresol. It readily combines with another mol. of a diazo-compound to form dis-azo-compounds (Nöling a. Kohn, B. 17, 366).

**Benzene-azo-p-cresol**  
C<sub>6</sub>H<sub>5</sub>-N<sub>2</sub>-C<sub>6</sub>H<sub>3</sub>(CH<sub>3</sub>)(OH) [1:5:2]. [109°]. Orange yellow plates. Soluble in dilute alkalis. Dyes a canary yellow. Formed by the action of diazo-benzene chloride on an alkaline solution of *p*-cresol. It does not yield a dis-azo-compound.

*Acetyl derivative* Ph-N<sub>2</sub>-C<sub>6</sub>H<sub>3</sub>(OAc): [68°]; yellow needles, v. sol. alcohol, ether, chloroform, and acetone.

*Benzoyl derivative* Ph-N<sub>2</sub>-C<sub>6</sub>H<sub>3</sub>(OBz): [113°]; yellow needles, sol. ether, benzene, and hot alcohol (Mazzara, G. 9, 425; Liebermann a. Kostanecki, B. 17, 130; Nöling a. Kohn, B. 17, 852).

**Benzene-azo-p-cresol-sulphonic acid**  
C<sub>6</sub>H<sub>5</sub>-N<sub>2</sub>-C<sub>6</sub>H<sub>3</sub>(CH<sub>3</sub>)(OH)(SO<sub>3</sub>H) [1:5:2:3]. Small reddish brown tables or needles. Easily soluble in water, sparingly in alcohol. Formed by the action of diazobenzene chloride on an alkaline solution of *p*-cresol-sulphonic acid [1:4:2]. A'Na: soluble reddish brown plates, dyes wool an orange yellow (Nöling a. Kohn, B. 17, 357; cf. Stebbins, A. O. J. 1, 465; 2, 263).

**Benzene-azo-ψ-cumenol**  
C<sub>6</sub>H<sub>5</sub>-N<sub>2</sub>-C<sub>6</sub>H<sub>3</sub>(CH<sub>3</sub>)<sub>2</sub>OH [1:3:5:6:2] (94°). Glistening brown prisms. In small quantities it can be distilled undecomposed. Insoluble in alkalis. Formed by combining diazo-benzene chloride with ψ-cumenol [70°]. On reduction it yields aniline and amido-ψ-cumenol [167°] (Liebermann a. Kostanecki, B. 17, 886).

**Benzene-azo-di-ethyl-amido-benzoic acid**  
C<sub>6</sub>H<sub>5</sub>-N<sub>2</sub>-C<sub>6</sub>H<sub>3</sub>(NEt<sub>2</sub>)CO<sub>2</sub>H [1:4:2]. [125°]. From diazo-benzene nitrate and di-ethyl-*m*-amido-benzoic acid. Red crystals with violet lustre

(from alcohol). Insol. water, sl. sol. alcohol and ether. Salts: BaA', -AgA' (Griess, B. 10, 526).

**Benzene-azo-ethyl-(β)-naphthyl-amine**  
C<sub>6</sub>H<sub>5</sub>-N<sub>2</sub>-C<sub>10</sub>H<sub>7</sub>NHET. [103°]. Red needles. Soluble in alcohol &c. with an orange-red colour, insol. water. It forms bluish-violet salts with acids. Formed by heating ethyl-(β)-naphthyl-nitrosamine with an acetic acid solution of aniline at 100°. Also produced by combining diazo-benzene with ethyl-(β)-naphthylamine.

*Nitrosamine* C<sub>6</sub>H<sub>5</sub>.N<sub>2</sub>.C<sub>10</sub>H<sub>7</sub>NH(=NO): [97°]; red crystals (Henriques, B. 17, 2669).

**Benzene-azo-ethyl-phenylene-diamine**  
C<sub>6</sub>H<sub>5</sub>.N<sub>2</sub>.C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub>NHET. *Ethyl-chrysoidine*. Dyes a redder shade than ordinary chrysoidine. Formed by combining ethyl-*m*-phenylene-diamine with diazo-benzene. - B'HCl: reddish-brown needles with violet-blue reflection, soluble in water and alcohol with an orange colour. - B'H<sub>2</sub>Cl<sub>2</sub>PtCl<sub>4</sub>; insoluble red pp. (Nöling a. Stricker, B. 19, 547).

**Benzene-azo-indoxyl**

[236°]. Red needles or thick orange prisms. Sol. alcohol and alkalis, v. sl. sol. water. Formed by the action of diazo-benzene chloride on indoxyl (Bueyer, B. 16, 2190).

**Benzene-azo-methane** C<sub>6</sub>H<sub>5</sub>-N<sub>2</sub>-CH<sub>3</sub>. *Azo-phenyl-methyl*. (c. 150°). Yellow oil of peculiar odour. Very volatile, and readily distils with steam. Formed by oxidation of *s*-phenyl-methyl-hydrazine C<sub>6</sub>H<sub>5</sub>.NH.NH.CH<sub>3</sub> with HgO (Tafel, B. 18, 1742).

**Benzene-azo-methazonic acid**  
Ph-N<sub>2</sub>-C<sub>6</sub>H<sub>3</sub>N<sub>2</sub>O<sub>3</sub>. [164°]. From diazo-benzene nitrate and an aqueous solution of sodium methazonate (Kimich, B. 10, 141). Orange needles (from alcohol); insol. water. - Na<sub>2</sub>A''2aq. - BaA'' aq.

**Benzene-azo-di-methyl-amido-benzoic acid**  
Ph-N<sub>2</sub>-C<sub>6</sub>H<sub>3</sub>(NMe<sub>2</sub>)CO<sub>2</sub>H [1:4:2]. From diazo-benzene nitrate and di-methyl-*m*-amido-benzoic acid (Griess, B. 10, 527). Orange nodules.

**Benzene-azo-methyl-aniline**  
C<sub>6</sub>H<sub>5</sub>-N<sub>2</sub>-C<sub>6</sub>H<sub>4</sub>NHMe. *Methyl-amido-azo-benzene*. [180°]. Red needles. Sol. alcohol. Formed by heating benzene-azo-aniline with MeI. - B'HCl: violet needles.

*Acetyl derivative* C<sub>6</sub>H<sub>5</sub>.N<sub>2</sub>.C<sub>6</sub>H<sub>4</sub>NMeAc: [189°]; yellow silky needles (Berju, B. 17, 1401).

**Benzene-azo-di-methyl-aniline**  
C<sub>6</sub>H<sub>5</sub>.N<sub>2</sub>.C<sub>6</sub>H<sub>4</sub>NMe<sub>2</sub>. *Di-methyl-amido-azo-benzene*. [115°]. Yellow plates.

*Preparation*.—1. A solution of 74 pts. of NaNO<sub>2</sub> (100 p.c.) and 40 pts. of NaOH in 540 pts. of water is slowly added to a cooled solution of 100 pts. of aniline, 130 pts. of dimethylaniline, and 230 pts. of HCl in 360 pts. of water (Griess, B. 10, 525; Möhlau, B. 17, 1490).—2. By heating benzene-azo-aniline with MeI (Berju, B. 17, 1402; C. C. 1884, 871).

*Methylo-iodide* B'MeI. [174°]. Plates.

**Benzene-azo-methyl-ketole**  
C<sub>6</sub>H<sub>5</sub>-N<sub>2</sub>-C<sub>6</sub>H<sub>4</sub>N. [116°]. Yellow needles. Formed by the action of diazo-benzene-chloride upon methyl-ketole in aqueous alcoholic solution in presence of sodium-acetate (Fischer, B. 19, 2990).

**Benzene-azo-methyl-phenylene-diamine**  
 $C_6H_5.N_2.C_6H_4(NH_2)NHMe$ . *Methyl-chrysoidine*.  
 Minute orange prisms. Dyes a somewhat redder  
 shade than ordinary chrysoidine. Formed by  
 combining diazobenzene with methyl-*m*-phenyl-  
 ene diamine (Nölting a. Stricker, *B.* 19, 549).

**Benzene-azo-( $\alpha$ )-naphthol**  
 $C_{10}H_7-N_2-C_{10}H_6OH$ . ( $\alpha$ -Naphthoquinone-  
*phenyl-hydrazide*. [206°]). Small needles with  
 blue reflection (from alcohol) or flat needles or  
 plates (from benzene).

**Formation.**—1. By combining ( $\alpha$ )-naphthol  
 with diazobenzene. —2. By the action of phenyl-  
 hydrazine hydrochloride upon ( $\alpha$ )-naphthoquinone  
 suspended in acetic acid.

**Reactions.**—Dissolves both in acids and  
 alkalis. Bromine forms two bromo-derivatives  
 [185°], and [196°] (Mazgary, *G.* 11, 271).

**Salts.**—A'K': crystalline pp. The hydro-  
 chloride, hydrobromide, and sulphate  
 form bluish or greenish glistening needles,  
 sparingly soluble in water, alcohol, and acetic  
 acid (Typke, *B.* 10, 1580).

*Methyl ether* A'Me: [83°]; brown crystals.  
*Ethyl ether* A'Et: [100°]; long needles.

**Acetyl derivative**  $C_{10}H_6N_2(OAc)$  [128°];  
 small brownish-red needles (Liebermann, *B.* 16,  
 2858; Zincke a. Bindewald, *B.* 17, 3026).

**Benzene-o-azo-( $\alpha$ )-naphthol**

*quinone-phenyl-hydrazide*. Formed by the action  
 of phenylhydrazine hydrochloride upon ( $\beta$ )-  
 naphthoquinone. Long red needles; sol. hot  
 alcohol and hot acetic acid. It does not combine  
 with acids or bases. By  $SnCl_2$  it is reduced to  
 ( $\beta$ )-amido-( $\alpha$ )-naphthol. By treatment in hot  
 acetic acid solution with  $HNO_3$  it gives di-nitro-  
 ( $\alpha$ )-naphthol. By the action of alkaline reducing  
 agents it is at once converted into ( $\beta$ )-amido-  
 ( $\alpha$ )-naphthol; no intermediate product could be  
 detected (Zincke a. Bindewald, *B.* 17, 3030;  
 Zincke a. Rathgen, *B.* 19, 2182).

**Bromo-derivative**  $C_{10}H_6N_2Br_2O$ ;  
 [215°–219°]; slender red needles.

**Formation.**—By the action of a diazobenzene  
 salt on an alkaline solution of  $\beta$ -naphthol. It  
 is *not* formed by the action of diazobenzene  
 hydrate on finely divided ( $\beta$ )-naphthol (difference  
 from ( $\alpha$ )-naphthol) (Liebermann, *B.* 16, 2858).

**Properties.**—Golden plates or long metallic  
 glistening needles. Soluble in ether, benzene,  
 ligroine and  $CS_2$ . Dissolves in  $H_2SO_4$  with a  
 magenta-red colour. Is insoluble in caustic  
 alkalis. It has a slightly basic character,  
 dissolving in  $HCl$  with a red colour, and form-  
 ing an unstable hydrochloride crystallising in  
 needles. By  $SnCl_2$  it is reduced to ( $\alpha$ )-amido-  
 ( $\beta$ )-naphthol and aniline. The same reduction  
 products are also formed at once by treatment  
 with alkaline reducing agents (*e.g.* zinc-dust and  
 $NaOH$ , ammonium sulphide, &c.); no inter-  
 mediate product was detected. When treated  
 with acetic acid solution with  $HNO_3$ , it gives  
 in light

di-nitro-( $\beta$ )-naphthol (Zincke a. Rathgen, *B.*  
 19, 2482).

**Bromo-derivative**  $C_{10}H_6Br_2O$ : [168°].  
 Brownish-red needles (Zincke a. Bindewald, *B.*  
 17, 3031).

**Benzene-azo-( $\alpha$ )-naphthol sulphonic acid**  
 $C_{10}H_7-N_2-C_{10}H_6(SO_3H)(OH)$ . From sodium ( $\alpha$ )-  
 naphthol sulphonate, aniline nitrate, and  $KNO_3$ ,  
 (Hofmann, *B.* 10, 1378). Slender brown needles  
 (from alcohol mixed with  $HCl$  aq). Dyes orange.  
 — $AgA'$ . — $BaA'$ .

**Benzene-azo-( $\beta$ )-naphthol sulphonic acid**  
 $C_{10}H_7-N_2-C_{10}H_6(HSO_3)OH$ . Brown needles with  
 yellowish-green reflex. Difficultly soluble in  
 water and alcohol. Prepared by the action of  
 an alkaline solution of ( $\beta$ )-naphthol-sulphonic  
 acid on diazobenzene nitrate or chloride. — $A'_2Ba$ .  
 Yellowish red microscopic leaflets. Slightly  
 soluble in water (Griess, *B.* 11, 2197). Its  
 absorption-spectrum has been examined by  
 Hartley (*C.* *J.* 51, 196).

**Benzene-azo-( $\beta$ )-naphthol disulphonic acid**  
 $C_{10}H_7-N_2-C_{10}H_6(SO_3H)_2(OH)$ . From sodium ( $\beta$ )-  
 naphthol disulphonate and diazobenzene nitrate.  
 Sol. water. Barium salt is al. sol. water  
 (Stebbins, jun., *A. C.* *J.* 2, 236).

**Benzene-azo-( $\alpha$ )-naphthylamine**  
 $C_{10}H_7-N_2-C_{10}H_6NH_2$ . Prepared by the action  
 of diazobenzene sulphate on ( $\alpha$ )-naphthyl-  
 amine (Griess, *T.* 1861, iii. 679; Weselsky a.  
 Benedikt, *B.* 12, 228). — $W'H_2SO_4$  aq: micro-  
 scopic needles; difficultly soluble in water.

**Benzene-azo-( $\beta$ )-naphthylamine**

**Benzene-hydratrimido-naphthalene**. [101°]. Red  
 trimetric tables or long fine red needles. Easily  
 soluble in alcohol and acetic acid, insoluble in  
 water. Dissolves in strong  $H_2SO_4$  with a blue  
 colour. Its salts exist only in presence of a large  
 excess of acid. Formed by combination of  
 diazobenzene with ( $\beta$ )-naphthylamine. By boiling  
 with 20 p.c. aqueous  $H_2SO_4$  it is slowly decom-  
 posed into ( $\beta$ )-naphthylamine, phenol, and  
 nitrogen. On reduction it gives aniline and  
 (1,2)-naphthylene diamine. On oxidation it  
 gives benzene-azimido-naphthalene (*q. v.*).

**Acetyl derivative**  $C_{10}H_6AcN_2$ . [153°].  
 Small red needles, easily soluble in alcohol, in-  
 soluble in water.

**Benzoyl derivative**  $C_{10}H_6BzN_2$ : [163°],  
 red crystals (Lawson, *B.* 18, 796).

**Benzene-o-azo-nitro-benzene**

$C_6H_5-N_2-C_6H_4(NO_2)$  [1:2]. **Nitro-azobenzene**.  
 [123°]. Formed by nitration of benzene-azo-ben-  
 zene in acetic acid at 100°. Orange-yellow  
 minute needles. V. sol. alcohol. Alcoholic  
 $NaOH$  gives a beautiful emerald-green coloura-  
 tion; by long boiling or by treatment with sodium-  
 amalgam it is further reduced to a compound  
 $C_{12}H_{11}N_3O$ . Tin and  $HCl$  or ammonium sulphide  
 first reduce it to benzene-o-azo-aniline and then  
 to aniline, and *o*-phenylene-diamine. By bro-  
 mination in acetic acid it yields bromo-nitro-  
 benzene [123°] or [132°] (Janovsky a. Erb, *B.*  
 19, 2157; 20, 360; *M.* 8, 56).

**Benzene-p-azo-nitro-benzene**

$C_6H_5.N_2.C_6H_4NO_2$  [1:4]. [137°]. Small yellow  
 needles (from alcohol). Formed by nitration of  
 benzene-azo-benzene. By  $NH_4HS$  it is reduced

to ordinary benzene-azo-aniline. Alcoholic  $\text{NH}_4\text{HS}$  produces red crystals of an intermediate

$\text{C}_6\text{H}_5\text{N}_2\text{C}_6\text{H}_4\text{NOH}$   
nitrolic acid (2) [134°],

which forms a blue solution in  $\text{NaOH}$  aq.  $\text{K}_2\text{FeCy}_6$  reoxidises it to benzene-azo-*p*-nitrobenzene. By complete reduction it yields aniline and *p*-phenylene-diamine (Laurent a. Gerhardt, *A.* 75, 73; Janovsky, *B.* 18, 1133; *M.* 6, 164, 455).

**Benzene-azo-tri-nitro-benzene**  
 $\text{C}_6\text{H}_5\text{N}_2\text{C}_6\text{H}_2(\text{NO}_2)_3$ . [112°]. By action of  $\text{HgO}$  on an alcoholic solution of the corresponding hydrazo-compound (E. Fischer, *A.* 190, 133). Slender red prisms (from alcohol).

**Benzene-azo-nitro-iso-butane**  
 $\text{C}_6\text{H}_5\text{N}_2\text{CH}(\text{NO}_2)\text{Pr}$ . From diazobenzene nitrate and potassium nitro-iso-butane (Züblin, *B.* 10, 2088). Oil. Forms an orange solution in alkalis.

**Benzene-azo-nitro-ethane**  $\text{C}_6\text{H}_5\text{N}_2\text{C}_2\text{H}_5$  i.e.  $\text{C}_6\text{H}_5\text{N}_2\text{CH}(\text{NO}_2)\text{CH}_3$ . [137°]. From diazobenzene nitrate and sodium nitroethane (V. Meyer a. Ambühl, *B.* 8, 751, 1073). Rectangular orange crystals; v. sol. alcohol and ether, insol. cold water, sol. aqueous alkalis forming a blood-red solution. Dyes silk yellow. Conc.  $\text{H}_2\text{SO}_4$  forms a violet solution. It crystallises unaltered from aqueous  $\text{NH}_3$  (Barbieri, *B.* 9, 386) but such a solution gives pps. with metallic salts.

Salts.— $\text{C}_6\text{H}_5\text{K}_2\text{N}_2\text{O}_2\text{aq.}$ — $\text{C}_6\text{H}_5\text{Na}_2\text{N}_2\text{O}_2\text{7aq.}$ — $\text{C}_6\text{H}_5\text{ZnN}_2\text{O}_2\text{3aq.}$ — $\text{C}_6\text{H}_5\text{PbN}_2\text{O}_2\text{PbO2aq.}$

**Benzene-az-nitro-methane**  
 $\text{C}_6\text{H}_5\text{N}_2\text{CH}(\text{NO}_2)$ . [153°]. From diazobenzene nitrate and sodium nitromethane in very dilute solution (Fries, *B.* 8, 1078). Slender red needles (from alcohol). Conc.  $\text{H}_2\text{SO}_4$  gives a purple solution. Decomposed by  $\text{HCl}$  aq. only after long boiling.

**Benzene-azo-tri-nitro-phenol**  
 $\text{C}_6\text{H}_2\text{N}_2\text{C}_6\text{H}_2(\text{NO}_2)_3\text{OH}$ . Long brown prisms. Insol. cold, sl. sol. hot, water; v. sol. alcohol. Explodes at 70°. Dyes silk and wool orange-yellow. Prepared by the action of a salt of diazobenzene on an alcoholic solution of picric acid (Stebbins, jun., *A. C. J.* 1, 465; 2, 236; *C. N.* 41, 117; *J.* 13, 43).

**Benzene-azo-nitro-propane**  
 $\text{C}_6\text{H}_5\text{N}_2\text{CH}(\text{NO}_2)\text{CH}_2\text{CH}_3$ . [99°]. From potassium nitropropane and diazobenzene nitrate (V. Meyer, *B.* 9, 386). Orange needles; sol. alkalis.

**Benzene-azo-iso-nitro-propane**  
 $\text{C}_6\text{H}_5\text{N}_2\text{C}(\text{NO}_2)(\text{CH}_3)_2$ . From aqueous diazobenzene nitrate and potassium nitro-isopropane. Oil; insol. alkalis (V. Meyer a. Ambühl, *B.* 8, 1076).

**Benzene-azo-o-oxy-benzoic-acid**  
 $\text{C}_6\text{H}_3\text{N}_2\text{C}_6\text{H}_3(\text{OH})\text{CO}_2\text{H}$ . From diazobenzene nitrate and an alkaline solution of salicylic acid (Stebbins, jun., *A. C. J.* 1, 465; *B.* 13, 715; *C. N.* 41, 117). Orange-red needles; insol. water, v. sol. alcohol or ether. Dyes wool orange.

**Benzene-azo-di-oxy-naphthalene**  
 $\text{C}_6\text{H}_5\text{N}_2\text{C}_{10}\text{H}_6(\text{OH})_2$  or  $\text{C}_{10}\text{H}_6(\text{OH})_2\text{N}_2\text{C}_6\text{H}_5$  {  
Oxy-(a)-naphthoquinone phenyl-hydrazide. [230°]. Formed by the action of phenylhydrazine on oxy-naphthoquinone in aqueous-alcoholic solution. Yellowish-red glistening needles. V. sol. ether, hot alcohol, and but acetic acid.

**Salts.**—The alkali salts form slender orange needles, sol. alcohol.— $\text{A}'\text{Ba}$  10aq; yellowish-brown plates or long red needles.— $\text{A}'\text{Ca}$  4aq; slender orange needles.— $\text{A}'\text{Ag}$ ; reddish-brown amorphous pp.

*Acetyl derivative*: [179°]; red needles.  
*Methyl ether*  $\text{A}'\text{Me}$ : [175°]; red needles.

*Ethyl ether*  $\text{A}'\text{Et}$ : [173°]; yellowish-red needles, v. sol. hot alcohol and hot acetic acid.

*Bromo-derivative*  $\text{C}_{16}\text{H}_{11}\text{BrO}_2\text{N}_2$ : [198°]; large red needles, sl. sol. alcohol (Zincke a. Thelen, *B.* 17, 180).

**Benzene-azo-phenol**  $\text{C}_6\text{H}_5\text{N}_2\text{C}_6\text{H}_4\text{OH}$  [14°]. *Oxy-azo-benzene*. [154°].

*Formation*.—1. A product of the action of  $\text{BaCO}_3$  on diazobenzene nitrate in the cold (Griess, *A.* 137, 84).—2. From benzene-azo-benzene sulphonic acid by potash fusion (Griess, *A.* 154, 211).—3. From diazo-benzene nitrate and  $\text{C}_6\text{H}_5\text{OK}$  (Kekulé a. Heidegh, *Z.* [2] 6, 384).—4. By the action of *p*-nitroso-phenol (20 pps.) on aniline acetate (60 pps.) (Kimich, *B.* 8, 1499).—5. By gently warming benzene-azoxy-benzene,  $\text{C}_6\text{H}_5\text{N}_2\text{O}\text{C}_6\text{H}_5$ , with  $\text{H}_2\text{SO}_4$  (Wallach, *B.* 13, 525; 14, 2617).

*Properties*.—Purple pyramidal plates. Insol. cold water, sol. alkalis; v. sol. alcohol. Bromine in acetic acid gives a compound [139°].

**Salt**.— $\text{AgA}'$ .

*Acetyl derivative*.— $\text{Ph.N}_2\text{C}_6\text{H}_4\text{OAc}$ . [85°]. (above 300°). Golden scales.

*Methyl ether*.— $\text{Ph.N}_2\text{C}_6\text{H}_4\text{OMe}$  [54°]. Yellow scales.

**Benzene-azo-phenol sulphonic acid**  
 $\text{C}_6\text{H}_5\text{N}_2\text{C}_6\text{H}_4(\text{OH})(\text{SO}_3\text{H})$  [14:3]. From diazobenzene nitrate and an alkaline solution of phenol *o*-sulphonic acid (Griess, *B.* 11, 2194). Red needles or tables; sol. water and alcohol.— $\text{KA}'$ .

**Benzene-azo-phenol sulphonic acid**  
 $\text{C}_{12}\text{H}_9\text{N}_2(\text{OH})(\text{SO}_3\text{H})$ . From benzene-azo-phenol and fuming  $\text{H}_2\text{SO}_4$  (Tschirvinsky, *B.* 6, 560).— $\text{BaA}'_2\text{2aq.}$ — $\text{CuA}'_2\text{6aq.}$ — $\text{MgA}'_2\text{6aq.}$ — $\text{KA}'$ .

**Benzene-azo-phenol di-sulphonic acid**  
 $\text{C}_{12}\text{H}_9\text{N}_2(\text{OH})(\text{SO}_3\text{H})_2$ . From azoxybenzene (1 pt.) and fuming  $\text{H}_2\text{SO}_4$  (10 pps.) by heating for 3 hours at 150° (Limpricht a. Wilsing, *A.* 215, 232; *B.* 15, 1297). Orange needles, v. e. sol. water, v. sol. dilute acids.

Salts.— $\text{KA}'$  2aq; red needles, sl. sol. cold water; not attacked by  $\text{Br}$ .— $\text{BaA}'$  aq; orange crystalline pp.— $\text{Ag}_2\text{A}'$ : red crystalline pp.

**Benzene-azo-phenol tetra-sulphonic acid**  
 $\text{C}_{12}\text{H}_9\text{N}_2(\text{OH})(\text{SO}_3\text{H})_4$ . From azoxybenzene and fuming  $\text{H}_2\text{SO}_4$  (L. a. W.). Will not crystallise. Salts.— $\text{C}_{12}\text{H}_9\text{N}_2(\text{OK})(\text{SO}_3\text{K})_4$  aq; long yellow needles. Giv. swith bromine-water a pp. of tri-bromo-phenol [92°].— $\text{Ba}_4\text{A}'$  7aq; orange crystalline pp.

**Other benzene-azo-phenol sulphonic acids** are described as *Oxy-benzene-azo-benzene sulphonic acids*, and *sulpho-benzene-azo-phenol sulphonic acids*.

**Benzene-azo-diphenylamine**  
 $\text{C}_6\text{H}_5\text{N}_2\text{C}_6\text{H}_4\text{NH.C}_6\text{H}_5$  [82°] (O. N. Witt, *C. J.* 35, 185; *B.* 12, 259). A solution of diphenylamine (17 g.) in alcohol (100 c.c.) is added to a solution of diazo-benzene chloride (14 g.) in alcohol (50 g.). The brown mixture is cooled with ice, and alcoholic  $\text{NMe}_3$  (used instead of  $\text{NH}_3$ , because  $\text{NMe}_3\text{HCl}$  is soluble in alcohol) is

added from time to time to neutralise the liquid. The oil which separates is purified by a lengthy process, and finally crystallised from benzoline.

**Properties.**—Golden leaflets or needles. Sol. benzene, alcohol, and ether. HCl turns its alcoholic solution violet; steel-grey crystals of the hydrochloride separating. The base forms a green solution with  $H_2SO_4$  turned, by adding water, into indigo, violet, and finally red. With amyl nitrite and acetic acid it forms a nitrosamine,  $Ph.N(NO).C_6H_4.N_2Ph$ , [120°], forming orange needles, sparingly soluble in alcohol and acetic acid, readily in benzene.

#### Benzene-azo-*m*-phenylene diamine

$C_6H_5-N_2-C_6H_4(NH_2)_2$  [1:2:4]. *Chrysoidine*. [117.5°] (W.); [110°] (H.). From diazobenzene salts and *m*-phenylene diamine (Witt, B. 10, 850, 654; Hofmann, B. 10, 213, 388; Griess, B. 10, 390). Slender yellow needles (from water); sl. sol. water, v. sol. alcohol. Reduced by ammonium sulphide at 150° to aniline and (1, 2, 4)-tri-amido-benzene. The absorption-spectrum has been examined by Hartley (C. J. 51, 178).— $B''HCl$ : black octahedra or small red silky crystals; its aqueous solution is orange, but turned red by  $HCl-B''H_2PtCl_6-B''HNO_3$ .

#### Di-acetyl derivative

$Ph-N_2-C_6H_4(NHAc)_2$  [251°].

**Benzene-azo-*m*-phenylene-diamine sulphonio acid**  $C_6H_5-N_2-C_6H_4(NH_2)(SO_3H)$ . *Chrysoidine sulphonio acid*. Glistening spangles or needles. Sl. sol. water and alcohol. Prepared by the action of diazobenzene-chloride on a salt of *m*-phenylene-diamine sulphonio acid.  $A'Na$ : soluble golden needles— $A''Ba$ : orange needles (Ruhemann, B. 14, 2655). By the sulphonation of chrysoidine an isomeric acid is formed (v. Di-amido-benzene-azo-benzene sulphonio acid').

**Benzene-azo-di-phenyl-methyl-pyrrol-carboxylic acid**  $C_{12}H_{11}O_2N_3$ , i.e.  $HO_2C.CMe$

by saponification of its ethyl ether, which is formed from an acetic acid solution of aceto-phenone-aceto-acetic ether (1 mol.) and benzene-*p*-azo-aniline (1 mol.) on standing for two days. Large red crystals. V. sol. alcohol, ether, and benzene; sl. sol. ligroin and acetic acid; insol. water, and conc. acids. Gives Laubenheimer's reaction.

**Ethyl ether EtA'**: [123°]; splendid red crystals; v. sol. benzene and ligroin, sl. sol. alcohol, ether, and acetic acid (Paul a. Schneider, B. 19, 3162).

#### Benzene-azo-phenyl-( $\beta$ )-naphthyl-amine

$C_{12}H_{11}N_3$ , i.e.  $C_6H_5-N_2-C_{10}H_7NHC_6H_5$  or

**Benzene-phenyl-hydrazimido-naphthalene**. [142°]. Obtained by combining diazo-benzene chloride with phenyl-( $\beta$ )-naphthyl-amine in alcoholic solution. It is also formed by the action of an acetic acid solution of aniline upon phenyl-( $\beta$ )-naphthyl-nitrosamine. Small red glistening needles.

**Reactions.**—1. By heating with conc. HCl it yields naphthophenazine  $C_{12}H_8$  and

aniline.—2. **Bromine** acting on the hot acetic acid solution forms tetra-bromo-phenyl-( $\beta$ )-naphthylamine with evolution of nitrogen.—3. It is reduced by  $SnCl_2$  to aniline and phenyl-*o*-naphthylene diamine  $C_{10}H_7(NH_2)NHC_6H_5$ .—4. By oxidation with  $K_2Cr_2O_7$  in acetic acid solution the chromate of a powerful ammonium-base  $C_{22}H_{16}N_4OH$  is formed; the latter possibly

has the constitution  $C_{10}H_8$ .  
v. *Naphthalene di-phenyl-azammonium-hydrate* (Henriques, B. 17, 2671; Zincke a. Lawson, B. 20, 1167).

#### Benzene-azo-di-phenyl-thio-urea

$C_6H_5-N_2-C_6H_4NH.CS.NHPh$ . [179°]. Plates. Formed by combination of phenyl-mustard-oil with benzene-azo-aniline (Berju, B. 17, 1405).

#### Benzene-azo-pyrogallol

$C_6H_3-N_2-C_6H_2(OH)_3$ . Prepared by adding an aqueous solution of diazobenzene nitrate to an alkaline solution of pyrogallol (Stebbins, jun., A. C. J. 1, 465; 2, 236; B. 13, 44; C. N. 41, 117). Red needles (from acetic acid). Insol. water, sol. alcohol. Its alcoholic solution dyes silk and wool orange.

#### Benzene-*p*-azo-resorcin

$C_6H_5-N_2-C_6H_2(OH)_2$  [1:2:4]. [161°] or [170°]. From diazobenzene nitrate and resorcin (Typke, B. 10, 1577; Wallach, B. 15, 2819; It. Meyer, B. 16, 1329). Formed also by gently warming diazobenzene anilide with resorcin, aniline being eliminated (Heumann a. Oeconomides, B. 20, 905). Slender orange needles [170°] or short red needles [161°], insol. water, sol. aqueous alkalis, v. e. sol. alcohol.

#### Acetyl derivative [102°].

**Mono-ethyl ether** [87°]. Scarlet needles.

**Diethyl ether** [70°]. Yellowish-red needles.

**Benzene-*o*-azo-resorcin**  $C_6H_5.N_2.C_6H_3(OH)_2$  [1:2:6]. Formed in small quantity (about 5 p.c.) in the preparation of the *p*-isomeric.

**Mono-ethyl ether**  $C_6H_5.N_2.C_6H_3(OH)(OEt)$

[150°]. Long fine scarlet needles; v. e. sol. alcohol and ether, insol. water; dissolves in aqueous alkalis with a brownish-red colour.

**Di-ethyl-ether**  $C_6H_5.N_2.C_6H_3(OEt)_2$  [90°].

Large red glistening tables; v. sol. ether, hot alcohol and acetic acid, insol. water (Fukall, B. 20, 1145).

#### Benzene-azo-thymol

$C_6H_5-N_2-C_6H_4MePr(OPr)$  [1:2:5:4] [85°–90°]. From diazobenzene chloride, and an alkaline solution of thymol (Mazzara, G. 15, 52, 228). Reddish-yellow needles. Reduction followed by oxidation gives thymoquinone.

#### Benzene-azo-thymol-sulphonic acid

$C_6H_5-N_2-C_6H_3(CH_3)(SO_3H)$  [216°]. Small yellow prisms. Yellow colouring matter. Prepared by the action of diazobenzene chloride on a salt of thymol-sulphonic acid. Salts.— $A'Na$ : small yellow crystals.— $A''Ba$ : fine hair-like needles (Stebbins, B. 14, 2793).

**Benzene-*p*-azo-toluene**  $C_6H_5-N_2-C_6H_4(CH_3)$  [63° corr.]. Formed by diazotising amido-benzene-*p*-azo-toluene  $C_6H_4(CH_3)-N_2-C_6H_4(NH_2)$  dissolved in alcohol and boiling the solution (Schultz, B. 17, 466). Orange-red plates; v. sol. alcohol. Volatile with steam. By treatment with alcoholic  $SnCl_4$  and  $H_2SO_4$  it is converted into a base melting at [116°].

**Benzene-azo-*m*-tolylene diamine**

$\text{O}_2\text{H}-\text{N}_2-\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)_2$ . Yellow needles. Easily soluble in alcohol, sparingly in water. Prepared by the action of diazobenzene chloride on (1, 2, 4) tolylene-diamine, [99°].— $\text{B}^*\text{HCl}$ : orange red needles (Stebbins, jun., *A. C. J.* 1, 465; *B.* 13, 717; *C. N.* 41, 117).

**Benzene-azo-*x*-ylenol**  $\text{C}_6\text{H}_4\text{N}_2\text{C}_6\text{H}_3\text{Me}_2\text{OH}$  [1:3:5:2]. [175°]. Formed by combining diazobenzene chloride with *m*-xylenol  $\text{C}_6\text{H}_3\text{Me}_2(\text{OH})$  [1:3:4] (Grevink, *B.* 19, 148). Slender brownish-red needles. V. sol. alcohol, ether, and benzene, insol. water. On reduction it yields aniline and *o*-amido-*m*-xylenol  $\text{C}_6\text{H}_3\text{Me}_2(\text{NH}_2)(\text{OH})$  [5:3:2:1].

**Bromo-amido-benzene-azo-*p*-bromo-aniline****Diacetyl derivative**

[2:5:1]  $\text{NHAc.C}_6\text{H}_4\text{Br}-\text{N}_2-\text{C}_6\text{H}_4\text{Br.NHAc}$  [1:5:2] [282°]. Formed by warming acetyl-bromo-nitro-aniline  $\text{C}_6\text{H}_4(\text{NHAc})\text{Br}(\text{NO}_2)$  [2:5:1] with zinc and conc.  $\text{NH}_4\text{Ac}$  (C. H. Matthiessen & Mixer, *Am.* 8, 847). Pale red substance.

***p*-Bromo-benzene-azo-benzene-*p*-sulphonic acid** [4:1]  $\text{C}_6\text{H}_4\text{Br}-\text{N}_2-\text{C}_6\text{H}_4(\text{SO}_3\text{H})$  [1:4]. Formed by sulphonation of benzene-*p*-azo-bromo-benzene or by bromination of benzene-azo-benzene-*p*-sulphonic acid. Flat needles (containing 3 aq).

**Salts.**— $\text{KA}'$ : rhombic tables. — $\text{NaA}'$ : yellow silky needles, sl. sol. water (Janovsky, *M.* 5, 162; *B.* 20, 358; *M.* 8, 53).

***m*-Bromo-benzene-azo-benzene-*p*-sulphonic acid** [3:1]  $\text{C}_6\text{H}_4\text{Br}-\text{N}_2-\text{C}_6\text{H}_3(\text{SO}_3\text{H})$  [1:4]. Formed by sulphonation of benzene-*m*-azo-bromo-benzene with fuming sulphuric acid. Glistening golden plates (containing 1½ aq).

**Salts.**— $\text{KA}'$ : yellow pearly pp. of microscopic needles. — $\text{NaA}'$ : pp. v. sl. sol. water (Janovsky & Erb, *B.* 20, 359).

***o*-Bromo-benzene-*o*-azo-bromo-benzene**

[2:1]  $\text{C}_6\text{H}_4\text{Br}-\text{N}_2-\text{C}_6\text{H}_3\text{Br}$  [1:2]. [185°]. A product of the bromination of benzene-azo-benzene in  $\text{HOAc}$  (Janovsky, *M.* 8, 50; *B.* 20, 397). Golden plates, sl. sol. alcohol. On nitration it gives a tri-nitro-derivative [135°].

***p*-Bromo-benzene-*p*-azo-bromo-benzene**

[4:1]  $\text{C}_6\text{H}_4\text{Br}-\text{N}_2-\text{C}_6\text{H}_4\text{Br}$  [1:4]. [205°]. Formed by bromination of benzene-azo-benzene (Werigo, *A.* 135, 178; 165, 189). Formed also by reduction of *p*-bromo-nitro-benzene with zinc-dust and alcoholic  $\text{KOH}$  (Schultz, *B.* 17, 465). Yellow needles. By alcoholic  $\text{SnCl}_2$  and  $\text{H}_2\text{SO}_4$  it is converted into a di-bromo-di-amido-diphenyl. Fuming  $\text{H}_2\text{SO}_4$  forms a sulphonic acid  $\text{C}_6\text{H}_3\text{Br}_2\text{N}_2\text{SO}_3\text{H}$  3aq (W.).

***m*-Bromo-benzene-*m*-azo-bromo-benzene**

[3:1]  $\text{C}_6\text{H}_4\text{Br}-\text{N}_2-\text{C}_6\text{H}_3\text{Br}$  [1:3]. [126°]. From the corresponding hydrazo-compound by  $\text{Fe}_2\text{Cl}_6$  (Gabriel, *B.* 9, 1407).

**Tri-bromo-benzene-azo-dimethyl-aniline**

$\text{C}_6\text{H}_3\text{Br}_3-\text{N}_2-\text{C}_6\text{H}_4(\text{NMe}_2)_2$ . [161°]. Formed by adding an alcoholic solution of dimethylaniline (2 mol.) to  $\text{C}_6\text{H}_3\text{Br}_3\text{N}_2\text{NO}_2$  (1 mol.). Crystalline pp.

Red plates (from glacial acetic acid). Insol. water, hardly soluble in alcohol. It combines with conc.  $\text{HCl}$  (Silberstein, *J. pr.* [2] 27, 124).

**Tri-bromo-benzene-azo-methyl-diphenylamine**

$\text{C}_6\text{H}_3\text{Br}_3-\text{N}_2-\text{C}_6\text{H}_4\text{NPhMe}$ . [188°]. From  $\text{C}_6\text{H}_3\text{Br}_3\text{N}_2\text{NO}_2$  and  $\text{NPhMe}$  in alcohol. Small brownish-red plates (from glacial acetic acid). Insol. water, sl. sol. alcohol. Does not combine with  $\text{HCl}$  (Silberstein, *J. pr.* [2] 27, 126).

**Bromo-benzene-azo-( $\alpha$ )-naphthol**

[4:1]  $\text{C}_6\text{H}_4\text{Br}-\text{N}_2-\text{C}_{10}\text{H}_7\text{OH}$  [1:4]. [196°]. From *p*-diazobromo-benzene and ( $\alpha$ )-naphthol, or by bromination of benzene-azo-( $\alpha$ )-naphthol (Mazzara, *G.* 14, 271).

***p*-Bromo-benzene-azo-( $\beta$ )-naphthol**

[4:1]  $\text{C}_6\text{H}_4\text{Br}-\text{N}_2-\text{C}_{10}\text{H}_7\text{OH}$  [1:2]. [161°]. From *p*-diazobromo-benzene and ( $\beta$ )-naphthol, or from benzene-azo-( $\beta$ )-naphthol and bromine (Mazzara, *G.* 13, 438). Orange needles.

***p*-Bromo-benzene-*p*-azo-nitro-benzene**

[4:1]  $\text{C}_6\text{H}_4\text{Br}-\text{N}_2-\text{C}_6\text{H}_4(\text{NO}_2)$  [1:4]. [108°]. Formed by nitration of benzene-*p*-azo-bromo-benzene. Yellow needles. V. sol. alcohol (Janovsky & Erb, *B.* 20, 358).

**Bromo-benzene-azo-di-nitro-benzene (?)**

[4:1]  $\text{C}_6\text{H}_4\text{Br}-\text{N}_2-\text{C}_6\text{H}_3(\text{NO}_2)_2$  [1:2:4] (?). [190°]. Formed by nitrating benzene-*p*-azo-bromo-benzene (Janovsky, *M.* 8, 52).

***p*-Bromo-benzene-azo-nitro-ethane**

[4:1]  $\text{C}_6\text{H}_4\text{Br}-\text{N}_2-\text{CH}(\text{NO}_2)\text{CH}_3$ . [c. 187°]. From *p*-diazobromo-benzene nitrate and potassium nitro-ethane (Wald, *B.* 9, 393). Brick-red crystals (from dilute alcohol); sol. ether, glacial  $\text{HOAc}$ , and chloroform. Salt.— $\text{C}_6\text{H}_4\text{Br.N}_2\text{O}_2\text{Br}$ .

**Di-bromo-di-imido-di-hydro-anthracene-azo-di-bromo-di-imido-di-hydro-anthracene**  
 $\text{C}_{14}\text{H}_8\text{Br}_2\text{N}_2$  or

[233°]. Prepared by heating dibromo-nitro-anthraquinone with alcoholic  $\text{NH}_3$  (Claus & Diernfellner, *B.* 14, 1335). Red needles. Sublimable. Sl. sol. alcohol and ether, insol. water or aqueous acids and alkalis.

**Bromo-di-oxy-benzene-azo-bromo-hydroquinone. Tetra-methyl derivative**  
 $\text{C}_6\text{H}_3\text{Br}(\text{OMe})_2-\text{N}_2-\text{C}_6\text{H}_3\text{Br}(\text{OMe})_2$ . [220°]. Formed by bromination of the tetra-methyl derivative of di-oxy-benzene-azo-hydroquinone (Baessler, *B.* 17, 2125). Red crystalline solid, v. sol. benzene, chloroform, and  $\text{CS}_2$ , v. sl. sol. alcohol, insol. water.

**Bromo-sulpho-benzene-azo-benzene sulphonic acid**

[6:3:1]  $\text{C}_6\text{H}_3\text{Br}(\text{SO}_3\text{H})-\text{N}_2-\text{C}_6\text{H}_4\text{Br}(\text{SO}_3\text{H})$  [1:6:3]. Formed by oxidation of a neutral aqueous solution of bromo-amido-benzene sulphonic acid  $\text{C}_6\text{H}_4\text{Br}(\text{NH}_2)(\text{SO}_3\text{H})$  [4:3:1] with  $\text{KMnO}_4$ . Salts.— $\text{KA}''$  2aq; glistening red tables (Limpriecht, *B.* 18, 1422).

**Di-bromo-sulpho-benzene-azo-di-bromo-benzene sulphonic acid**

[2:6:4:1]  $\text{C}_6\text{H}_3\text{Br}_2(\text{SO}_3\text{H})_2-\text{N}_2-\text{C}_6\text{H}_3\text{Br}_2\text{SO}_3\text{H}$  [1:2:6:4]. From potassic di-bromo-*o*-amido-benzene sulphonate and  $\text{KMnO}_4$  (Rodatz, *A.* 215, 222). Red plates (containing 2aq). V. sol. water or alcohol. Reduced by  $\text{SnCl}_2$  to the original  $\text{C}_6\text{H}_3(\text{NH}_2)_2\text{Br}_2\text{SO}_3\text{H}$ . Salts.— $\text{KA}''$  2aq.— $\text{BaA}''$  3aq.— $\text{CaA}''$  4aq.— $\text{PbA}''$ .

**Chloride.**—[258°-262°]. Brown plates.

**Amide.**—Violet silky needles.

**Di-bromo-sulpho-benzene-azo-di-bromo-benzene sulphonic acid**

[4:6:3:1]  $\text{C}_6\text{H}_3\text{Br}_2(\text{SO}_3\text{H})_2-\text{N}_2-\text{C}_6\text{H}_3\text{Br}_2\text{SO}_3\text{H}$  [1:4:6:3]. From potassic di-bromo-amido-benzene sulphonate and  $\text{KMnO}_4$  (Rodatz, *A.* 215, 216). Slender red needles, containing 1½ aq (from water). V. sol. water, v. e. sol. alcohol. Reduced by  $\text{SnCl}_2$

to the original  $C_6H_5(NH_2)Br_2SO_3H$ . Salts.— $K_2A''3aq.$ — $BaA''aq.$ — $CaA''4aq.$ — $PbA''2\frac{1}{2}aq.$

*Chloride*.—[233°]. Brick-red needles.

*Amide*.—Microscopic orange needles (from alcohol). Does not melt.

An acid isomeric with the above may be got by the action of  $KMnO_4$  on the tetra-bromohydrazo-benzene di-sulphonic acid of Jordan, *A.* 202, 361.

Tri-bromo-sulpho-benzene-azo-tri-bromo-benzene sulphonic acid [2:4:6:3:1]

$C_6HBr_3(SO_3H)-N_2-C_6HBr_3(SO_3H)$  [1:2:4:6:3].

From potassic tri-bromo-*m*-amido-benzoate by  $KMnO_4$  (Rodatz, *A.* 215, 225). Flat orange needles. Reduced by  $SnCl_2$  to the original  $C_6H(NH_2)Br_3SO_3H$ .

$K_2A''3aq.$ — $BaA''2aq.$ — $CaA''7aq.$ — $PbA''4aq.$

*Chloride*.—[222°-224°]. Dark violet tables.

*Amide*.—Brown crystals that do not melt.

Di-bromo-sulpho-benzene-azo-( $\beta$ )-naphthol  $C_{10}H_7Br_2(SO_3H)-N_2-C_{10}H_7OH$  (Stebbins, *C. N.* 42, 44; *A. C. J.* 2, 236). From diazo-dibromobenzene sulphonic acid and an alkaline solution of ( $\beta$ )-naphthol.

Di-bromo-sulpho-benzene-azo-di-oxy-naphthalene  $C_{10}H_6Br_2(SO_3H)-N_2-C_{10}H_6(OH)_2$ . From diazo-dibromobenzene sulphonic acid and an alkaline solution of dioxynaphthalene. Needles (Griess, *B.* 11, 2199).

Bromo-sulpho-toluene-azo-bromo-toluene sulphonic acid  $N_2(C_6H_4BrMe.SO_3H)_2$  [1:2:4:5]. From potassic bromo-*p*-toluidine sulphonate (of Jensen) and  $KMnO_4$  (Kornatzki, *A.* 221, 186). Red tables with pointed ends. Salts.— $K_2A''4aq.$ — $BaA''5aq.$ — $CaA''4\frac{1}{2}aq.$ — $PbA''5aq.$

*Chloride*.—[226°]. Groups of red prisms.

*Amide*.—[above 260°]: red powder.

Di-bromo-sulpho-toluene-azo-di-bromo-toluene sulphonic acid  $N_2(C_6H_4BrMe.SO_3H)_2$  [1:2:2:2:5]. From potassic dibromo-*o*-toluidine sulphonate (of Hayduck) and  $KMnO_4$  (Kornatzki, *A.* 221, 188). Blood-red plates. Salts.— $K_2A''2aq.$ — $BaA''9aq.$ — $CaA''8aq.$ — $PbA''9aq.$

*Chloride*. [243°]. Red swallow-tailed plates.

*Amide*.—[218°]. Powder.

Di-butyl-*p*-amido-benzene-azo-di-butylaniline  $(C_4H_9)_2N.C_6H_4-N_2-C_6H_4N(C_4H_9)_2$ . Di-butyl-aniline-azylane. [158°]. Red needles. Formed by passing  $NO$  through an alcoholic solution of di-butyl-aniline.

*Periodide*.— $B''I_8$ : dark crystals with blue reflection (Lippmann & Fleissner, *B.* 15, 2142 and *B.* 16, 1421; *M.* 3, 713).

*m*-Carboxy-benzene-azo-aceto-acetic acid  $C_6H_4(CO_2H)-N_2-CHAc.CO_2H$ . Formed by the action of the sulphate of *m*-diazo-benzoic acid upon acetoacetic ether in alkaline aqueous solution (Griess, *B.* 18, 962). Small yellow plates or needles. Soluble in alcohol, nearly insoluble in water. Bitter taste.

*o*-Carboxy-benzene-*o*-azo-benzoic acid [3:1]  $C_6H_4(CO_2H)-N_2-C_6H_4(CO_2H)$  [1:2]. From *o*-Azo-benzoic acid. [238]. Mol. w. 270. From *o*-nitro-benzoic acid and sodium-amalgam (Griess, *B.* 10, 1868). Dark yellow hair-like needles. Insol. water; m. sol. alcohol.

Salts.— $BaA''7aq.$ — $BaA''9aq.$ — $Ag_2A''$ .

*Ethyl ether Et.A''*. [139°]. From *o*-nitro-benzoic ether by sodium-amalgam. Scarlet needles (Fittica, *J. pr.* [2] 17, 216).

#### *m*-Carboxy-benzene-*m*-azo-benzoic acid

$N_2(C_6H_4.CO_2H)_2$  [1:8]. *m*-Azo-benzoic acid. From *m*-nitro-benzoic acid by sodium-amalgam (Strecker, *A.* 129, 134). Amorphous powder, decomposed by heat, v. sl. sol. water, alcohol, and ether. Gives phenazine when distilled with lime. Its copper salt gives azobenzene on distillation.  $HgO$  and iodine gives an amorphous di-iodo-derivative,  $C_{12}H_8I_2N_2O_4$  (Benedikt *B.* 8, 386). Salts.— $BaA''5aq.$ — $Ag_2A''$ .

*Ethyl ether Et.A''*. [99°]. By the action of  $EtI$  on  $Ag.A''$  Golubeff (*B.* 7, 1651) obtained two bodies isomeric with this ether, one melting at 76°, the other being a monobasic acid.

#### *p*-Carboxy-benzene-*p*-azo-benzoic acid

$N_2(C_6H_4.CO_2H)_2$  [1:4]. From *p*-nitro-benzoic acid and sodium-amalgam (Beilstein & Reichenbach, *A.* 129, 144; Bilingier, *A.* 135, 154). Formed, together with azoxybenzoic acid, by boiling nitro-benzil with alcoholic  $KOH$  (Zinin, *Z.* 1868, 563). Flesh-coloured amorphous powder, insol. water, alcohol, and ether. Gives phenazine when distilled with lime. Salts.— $(NH_4)_2A''aq.$ — $Na_2A''$ .— $CaA''3aq.$ — $BaA''$ .— $Ag_2A''$ .

*Ethyl ether Et.A''*. [88°] (Fittica, *J. pr.* [2] 17, 216).

#### *m*-Carboxy-benzene-azo-malonic acid

$C_6H_4(CO_2H)-N_2-CH(CO_2H)_2$ . Formed by the action of the nitrate of *m*-diazo-benzoic acid on malonic ether in alkaline aqueous solution (Griess, *B.* 18, 962). Microscopic orange needles or plates. Easily soluble in alcohol.

Carboxy-benzene-azo-di-methyl-amido-benzoic acid  $C_6H_4(CO_2H).N_2.C_6H_4NMe.CO_2H$ . From *m*-diazo-benzoic acid and dimethyl-*m*-amido-benzoic acid (Griess, *B.* 10, 525). Brown pp.

#### *m*-Carboxy-benzene-azo-nitro-methane

$C_6H_4(CO_2H).N_2.CH_3(NO_2)$ . Formed by adding the nitrate of *m*-diazo-benzoic acid to a dilute aqueous alkaline solution of nitromethane (Griess, *B.* 18, 961). Yellowish-red plates. Sol. hot alcohol and ether, v. sl. sol. water.

#### *m*-Carboxy-benzene-azo-( $\beta$ )-naphthol

$C_6H_4(CO_2H)-N_2-C_{10}H_7(OH)$ . [235°]. Prepared by the action of *m*-diazo-benzoic acid on an alkaline solution of ( $\beta$ )-naphthol (Griess, *B.* 14, 2035). Reddish-yellow needles or plates. Sol. hot alcohol, sl. sol. cold alcohol and ether, insol. water.

Salts:  $A'_2Ba_3\frac{1}{2}aq.$ : red microscopic needles.  $A'K_2aq.$ : easily soluble yellow needles or plates.

*Ethyl ether A.Et.* [104°]. Yellowish-red needles or plates. Sol. ether, insol. water.

*Amide*.—Slender orange needles. Sl. sol. alcohol and ether, insol. water.

*m*-Carboxy-benzene-azo-( $\beta$ )-naphthol sulphonic acid  $C_6H_4(CO_2H)-N_2-C_{10}H_7(OH)(HSO_3)$ . Prepared by the action of *m*-diazo-benzoic acid on an alkaline solution of ( $\beta$ )-naphthol sulphonic acid (Griess, *B.* 14, 2036). Brown needles or plates. Sol. hot water, sl. sol. cold water and alcohol, insol. ether. Dyes wool and silk a splendid orange.— $A'_2H_2Ba_4aq.$ : orange pp. of slender needles.

*m*-Carboxy-benzene-azo-( $\beta$ )-naphthol di-sulphonic acid  $C_6H_4(CO_2H).N_2.C_{10}H_7(OH)(HSO_3)_2$ . Prepared by the action of *m*-diazo-benzoic acid on ( $\beta$ )-naphthol-( $\alpha$ )-disulphonic acid in alkaline solution (Griess, *B.* 14, 2037). Yellowish-red microscopic needles. Dyes silk and wool an orange scarlet.

**Salts.**—BaHA"6aq: red crystalline pp.—A", 12aq: red microscopic needles.

**Carboxy-benzene-azo-phenol v. Oxy-benzene-azo-benzoic acid.**

**Di-carboxy-benzene-azo-phthalic acid**  
 $C_6H_4(CO_2H)_2-N_2-C_6H_4(CO_2H)_2$ . *Azo-phthalic acid*. [about 250°]. Prepared by reduction of nitro-phthalic acid with sodium-amalgam (H. Müller; Claus a. May, *B.* 14, 1330). Small yellow needles: sl. sol. water, alcohol, and ether.

**Salts.**—A"Na, 10aq: yellow monoclinic prisms, v. sol. water.—A"K, 6aq: long yellow needles.—A"Mg, 18aq: large orange crystals.—A"Ag: yellow insoluble pp.—A"Ba: yellow insoluble pp.

**Di-carboxy-benzene-azo-terephthalic acid**  
 $5:2:1$   $C_6H_4(CO_2H)_2-N_2-C_6H_4(CO_2H)_2$  [1:5:2]. *Azo-terephthalic acid*.

**Formation.**—1. By oxidation of hydrazo-terephthalic acid with nitrous acid.—2. By reduction of nitro-terephthalic acid with sodium-amalgam (Homolka a. Löw, *B.* 19, 1032).

**Yellow needles.** Sol. alcohol and ether, sl. sol. water. Decomposes above 200°.

**Carboxy-naphthalene-azo-(β)-naphthoic acid**  
 $3:1$   $C_{10}H_7(CO_2H)-N_2-C_{10}H_7(CO_2H)$ . From a nitro-β-naphthoic acid by ammonium sulphide (Rukowsky, *B.* 5, 1022).

**exo-Carboxy-toluene-azo-phenyl-acetic acid**  
 $2O_2H.C_6H_4.C_6H_4-N_2-C_6H_4.CH_2.CO_2H$ . S. (cold alcohol) 0.375; (hot alcohol) 1.57. Insol. hot water, ether, and benzene. Does not melt below 300°. Formed by the action of sodium amalgam on nitro-phenyl-acetic acid [151] (Wittenberg, *Bl.* [2] 43, 111).

**Carboxy-toluene-azo-toluic acid**  
 $5:2:1$   $C_6H_4.Me(CO_2H)-N_2-C_6H_4.Me(CO_2H)$  [1:5:2]. *Azo-p-toluic acid*. [184]. From nitro-p-toluic acid by sodium amalgam (Fittica, *B.* 7, 1358). Minute yellow needles; m. sol. boiling water, v. sol. alcohol.

**p-Chloro-benzene-azo-benzene p-sulphonic acid** [4:1]  $C_6H_4Cl-N_2-C_6H_4(SO_3H)$  [1:4] [148°]. Formed by warming p-chloro-azo-benzene withuming sulphuric acid (10 p.c.  $SO_3$ ) at 60°-70°. Brown needles; v. e. sol. water and alcohol. It is reduced by  $SnCl_2$  to p-chloro-aniline and p-ulphanilic acid.

**Salts.**—A"Na: large orange-yellow pearly plates or small needles; sl. sol. cold water.—A"Ba: glistening flesh-coloured needles.—The Li, Mg, Ca, Ag, Cr, and Fe salts are white to lark-yellow needles; the Cu salt forms green plates; all are sparingly soluble.

**Chloride**  $C_6H_4Cl.N_2.C_6H_4.SO_3Cl$ : [130°]; glistening red prisms, easily soluble in alcohol and ether.

**Amide**  $C_6H_4Cl.N_2.C_6H_4.SO.NH_2$ : [211°]; yellowish-brown prisms; sol. hot alcohol, sparingly in ether and cold alcohol, insol. water (Mentha a. Heumann, *B.* 19, 2972).

**m-Chloro-benzene-m-azo-chloro-benzene**  
 $1:3$   $C_6H_4Cl-N_2-C_6H_4Cl$  [1:3]. *Azo-chloro-benzene* [101°]. Obtained by acting with  $FeCl_3$  on m-di-chloro-hydrazo-benzene in alcoholic solution (Laubenheimer, *B.* 8, 1025). Orange needles (from alcohol).

**p-Chloro-benzene-p-azo-chloro-benzene**  
 $4:1$   $C_6H_4Cl-N_2-C_6H_4Cl$  [1:4]. [181°]. From p-chloro-benzene-p-azo-nitro-benzene and alcoholic potash (Willgerodt, *B.* 15, 1002); or

from di-chloro-azoxybenzene and fuming  $H_2SO_4$  (Heumann, *B.* 5, 913, 918). Yellow needles.

**p-Chloro-benzene-azo-chloro-benzene sulphonic acid** [4:1]  $C_6H_4Cl.N_2.C_6H_4Cl.SO_3H$  [1:4:7]. Prepared by sulphonation of the preceding body (Calm a. Heumann, *B.* 13, 1183; 15, 2558). Slender reddish-yellow needles. Sol. water and alcohol. **Salts.**—A"Na: golden plates, sl. sol. cold water.—A"K: reddish-yellow glistening plates, sol. hot water, and alcohol.—A"Ag.—A"Ba: yellow crystalline pp.—A"Ca: golden yellow plates.—A"Pb: orange glistening plates.

**Chloride**  $C_6H_4Cl.N_2.SO_3Cl$ : [161°]. Long orange-red needles.

**Chloro-benzene-azo-chloro-phenol**  
 $[3:1]$   $Cl.C_6H_3-N_2-C_6H_3Cl(OH)$  [1:3:7]. [115°] Formed by the action of fuming  $H_2SO_4$  on m-di-chloro-azoxybenzene (Schultz, *B.* 17, 466). Brown plates.

**Chloro-benzene-azo-chloro-nitro-benzene**  
 $[4:1]$   $C_6H_4Cl-N_2-C_6H_4Cl(NO_2)$  [1:3:7]. [210°]. Prepared by reducing di-chloro-nitro-azoxybenzene with cold alcoholic  $NH_4HS$  (Calm a. Heumann, *B.* 13, 1184). Yellow needles. Sl. sol. alcohol.

**m-Chloro-benzene-azo-di-methyl-aniline**  
 $[3:1]$   $C_6H_4Cl-N_2-C_6H_4NMe_2$  [1:4]. [98°]. Yellow plates. Tolerably soluble in alcohol. Prepared by adding sodium nitrite (1 mol.) to a solution of m-chloroaniline (1 mol.) and dimethylaniline (1 mol.) in dilute  $H_2SO_4$  (Staedel a. Bauer, *B.* 19, 1955).

**p-Chloro-benzene-p-azo-nitro-benzene**  
 $[1:4]$   $C_6H_4Cl.N_2.C_6H_4(NO_2)$  [1:4]. [133°]. Formed by nitration of p-chloro-azo-benzene with fuming  $HNO_3$ . Yellow needles; v. sol. acetic acid and hot alcohol, sl. sol. cold alcohol, insol. water. It is reduced by  $SnCl_2$  to p-chloro-aniline and p-phenylene dianiline (Mentha a. Heumann, *B.* 19, 2971).

**p-Chloro-benzene-azo-phenol**  
 $C_6H_4Cl-N_2-C_6H_4(OH)$ . [152°]. Formed by gently warming p-chloro-diazo-benzene-chloro-anilide with phenol, p-chloroaniline being eliminated. Reddish-yellow needles (Heumann a. Oeconomidis, *B.* 20, 906).

**Cumene-azo-cumene**  $PrC_6H_4-N_2-C_6H_4.Pr$ . *Azo-cumene*. [108°]. From nitro cumene, [—35°], by sodium-amalgam (Pospekhoff, *J.* 11, 1886, 49). Thin yellow leaflets, sl. sol. cold alcohol.

**ψ-Cumene-azo-ψ-cumenol**  
 $[2:4:5:1]$   $C_6H_2(CH_3)_3-N_2.C_6H_2(CH_3)_3.OH$  [1:3:5:6:2]. [148°]. Formed by combining di-azo-cumene chloride (from ψ-cumidine) with ψ-cumenol [70°] (Liebermann a. Kostanvski, *B.* 17, 885). Orange needles. Insol. alkalis. Dissolves in  $H_2SO_4$  with an orange colour. No nitrogen is evolved on boiling with HCl.

**ψ-Cumene-azo-ψ-cumidine**  
 $[2:4:5:1]$   $C_6H_2Me_3-N_2.C_6HMe_3.NH_2$  [1:2:4:5:6]. [139°]. Prepared by the action of cumidine hydrochloride upon diazo-cumene-cumide (diazo-amido-cumene) dissolved in cumidine (Nöling a. Baumann, *B.* 18, 1147; *Bl.* [2] 42, 335). Orange plates (from alcohol). V. sol. ether. On reduction with  $SnCl_2$  it yields cumidine and cumylene-o-diamine. **Salt.**—BHCl: yellow crystalline powder; readily loses its HCl; dissolves in phenol with a yellowish-brown colour.

**Cuminic-azo-cuminic acid**  
 $PrC_6H_3(CO_2H)-N_2-C_6H_3.Pr.CO_2H$  [280°]. From

nitro-cumidine acid and sodium-amalgam (Alexéeff, *Bl.* [2] 88, 552; 42, 321; *J. R.* 1892, 198; Alexéeff a. Kissel, *Bl.* [2] 40, 72).

Ethers.— $\text{Me}_3\text{A}^+$ . [166°].— $\text{Et}_3\text{A}^+$ . [104°–108°].

#### Cymene-azo-cymene

$\text{C}_6\text{H}_4\text{MePr}-\text{N}_2-\text{C}_6\text{H}_4\text{MePr}$ . [86°]. From nitro-cymene by sodium-amalgam (Worigo, *Z.* 1864, 721). Cherry-coloured plates.

Ethyl-amido-benzene-azo-benzene-*p*-sulphonic acid [4:1]  $\text{C}_6\text{H}_4(\text{SO}_3\text{H})\text{N}_2\text{C}_6\text{H}_4\text{NH}_2$  [1:4]. *p*-Sulpho-benzene-azo-ethyl-aniline. [c. 244°]. Obtained by combining *p*-diazobenzene-sulphonic acid with ethyl-aniline in acid solution. Steel-blue needles. Nearly insol. alcohol and cold water, sl. sol. hot water. The sodium salt ( $\text{NaA}^+$ ) forms orange-red plates. On reduction with  $(\text{NH}_4)_2\text{S}$  it yields mono-ethyl-*p*-phenylene-diamine and *p*-sulphanilic acid (Berntsen a. Goske, *B.* 20, 329).

Di-ethyl-*p*-amido-benzene-azo-di-ethyl-aniline  $\text{C}_6\text{H}_4(\text{NEt}_2)-\text{N}_2-\text{C}_6\text{H}_4(\text{NEt}_2)$ . *Di-ethyl-aniline-azylane*. [170°]. Prepared by passing NO through an alcoholic solution of di-ethyl-aniline; yield 50 p.c. of the theoretical. Red monoclinic crystals,  $a:b:c = 1:7108:9493$ .  $\beta = 90^\circ 30'$ . V. sol. chloroform, sl. sol. cold alcohol.

Reactions.—1. Nitrous acid acting on the acetic solution gives *p*-nitro-di-ethyl-aniline.—2. On reduction it yields *u*-di-ethyl-*p*-phenylene-diamine.—3. Heated with ethyl iodide at 100° it gives tetra-ethyl-*p*-phenylene-diamine.—4. MeI at 100° gives di-methyl-di-ethyl-*p*-phenylene-diamine.

Salts.— $\text{B}^+\text{H}_2\text{ClPtCl}_2$ ; small brownish-red trimetric tables.—Ferrocyanide  $\text{B}^+\text{H}_2\text{FeCy}_6$ ; brown plates.—Picrate  $\text{B}^+(\text{C}_6\text{H}_4(\text{NO}_2)_2\text{OH})_2$ ; yellow sparingly soluble needles (Lippmann a. Fleissner, *B.* 15, 2136; 16, 1415; *M.* 3, 286, 788).

#### Di-ethyl-amido-benzene-azo-toluidine

##### Acetyl derivative

[4:1]  $\text{C}_6\text{H}_4(\text{NEt}_2)-\text{N}_2-\text{C}_6\text{H}_4\text{Me}(\text{NHAc})$  [1:6:3]. [159°]. From diazotised acetyl-tolylene-diamine  $\text{C}_6\text{H}_4(\text{NH}_2)\text{Me}(\text{NHAc})$  [1:6:3] and di-ethyl-aniline (Wallach, *A.* 234, 359).

##### *o*-Ethyl-benzene-*o*-azo-ethyl-benzene

[2:1]  $\text{C}_6\text{H}_4(\text{C}_2\text{H}_5)-\text{N}_2-\text{C}_6\text{H}_4(\text{C}_2\text{H}_5)$  [1:2]. [47° corr.]. Formed by reduction of *o*-nitro-ethyl-benzene with zinc dust and alcoholic NaOH (Schultz, *B.* 17, 473). Long red dimetric prisms,  $a:c = 1:3455$ . V. sol. alcohol. By treatment with  $\text{SnCl}_2$  and  $\text{HCl}$  in alcoholic solution it yields a di-amido-di-ethyl-diphenyl.

##### *p*-Ethyl-benzene-*p*-azo-ethyl-benzene

[4:1]  $\text{C}_6\text{H}_4(\text{C}_2\text{H}_5)-\text{N}_2-\text{C}_6\text{H}_4(\text{C}_2\text{H}_5)$  [1:4]. [63° corr.]. (above 340°). Formed by reduction of *p*-nitro-ethyl-benzene with zinc-dust and alcoholic NaOH (Schultz, *B.* 17, 475). Orange-red plates or thick prisms. V. sol. alcohol. By treatment with  $\text{SnCl}_2$  and  $\text{H}_2\text{SO}_4$  in alcoholic solution it yields a di-amido-di-ethyl-diphenyl.

##### *p*-Ethyl-phenyl-amido-benzene-*p*-azo-ethyl-di-phenylamine

[4:1]  $\text{C}_6\text{H}_4\text{NEtPh}-\text{N}_2-\text{C}_6\text{H}_4\text{NEtPh}$  [1:4]. [178°]. From ethyl-di-phenyl-amino and NO (Lippmann a. Fleissner, *M.* 4, 796). Monoclinic red crystals.

##### Ethyl-pyrrol-azo-( $\beta$ )-naphthalene

$\text{C}_6\text{H}_4\text{N}_2\text{C}_{10}\text{H}_7\text{NET}$ . [74°]. Obtained by adding ( $\beta$ )-diazonaphthalene chloride (1 mol.) to ethyl-pyrrol (1 mol.) dissolved in alcohol containing sodium acetate. Thick red tables. Sparingly

soluble in dilute  $\text{HCl}$ . Dissolves in conc.  $\text{H}_2\text{SO}_4$  with a dark reddish-yellow colour. The platinum-chloride forms small sparingly soluble red needles (O. Fischer a. Hepp, *B.* 19, 2255).

##### Ethyl-pyrrol-azo-*p*-toluene

$\text{C}_6\text{H}_4\text{MeN}_2\text{C}_6\text{H}_4\text{NET}$  probably  
 $\text{HC}=\text{CH}$   
 $\text{NET}$

[62°]. Formed by adding *p*-diazotoluene chloride (1 mol.) to an alcoholic solution of ethyl-pyrrol (1 mol.) containing sodium acetate. Thick red prisms. Dissolves in conc.  $\text{H}_2\text{SO}_4$  with a yellow colour, in dilute  $\text{HCl}$  with a reddish yellow colour. The platinum-chloride forms sparingly soluble red needles (O. Fischer a. Hepp, *B.* 19, 2257).

Iodo-carboxy-benzene-azo-iodo-benzoic acid  $\text{C}_6\text{H}_3(\text{CO}_2\text{H})-\text{N}_2-\text{C}_6\text{H}_3(\text{CO}_2\text{H})$ . *Azo-iodo-benzoic acid*. From *m*-amido-benzoic acid, iodine, and  $\text{HgO}$  (Benedikt, *B.* 8, 386).

##### Mesitylene-azo-mesitylene

$\text{C}_6\text{H}_3(\text{CH}_3)_3-\text{N}_2-\text{C}_6\text{H}_3(\text{CH}_3)_3$ . *Azo-mesitylene*. [75° corr.]. Prepared by oxidising an aqueous solution of mesidine hydrochloride (5 pts.) with a solution of 45 pts. of potassium ferricyanide and 10 pts. of  $\text{KOH}$  (Schultz, *B.* 17, 476). Thin red needles. Sol. hot alcohol. It does not appear to yield a hexa-methyl-benzidine by treatment with  $\text{SnCl}_2$  and  $\text{HCl}$  in alcoholic solution.

Methyl-amido-benzene-azo-benzene-sulphonic acid [4:1]  $\text{C}_6\text{H}_4(\text{SO}_3\text{H})\text{N}_2\text{C}_6\text{H}_4\text{NHMe}$  [1:4]. *p*-Sulpho-benzene-azo-methyl-aniline. Obtained by combining *p*-diazobenzene sulphonic acid with methyl-aniline in acid solution; yield 30 p.c. of theoretical. Also formed by the action of cold dilute acids upon *p*-sulpho-diazo-benzene-methyl-anilide  $\text{C}_6\text{H}_4(\text{SO}_3\text{H})\text{N}_2\text{NMeC}_6\text{H}_4$ . Steel blue needles, sl. sol. water. The sodium-salt ( $\text{A}^+\text{Na}$ ) forms large orange-red plates, v. sol. hot water. On reduction with  $(\text{NH}_4)_2\text{S}$  it yields *p*-sulphanilic acid and mono-methyl-*p*-phenylene-diamine (Berntsen a. Goske, *B.* 20, 925).

Di-methyl-amido-benzene-azo-benzene-sulphonic acid [4:1]  $\text{C}_6\text{H}_4(\text{NMe}_2)-\text{N}_2-\text{C}_6\text{H}_4\text{SO}_3\text{H}$  [1:4] *Helianthin*, or *Orange III*.

Preparation.—1. From dimethylaniline and *p*-diazobenzene sulphonic acid (Griess, *B.* 10, 525).—2. Dimethylamido-azobenzene (1 pt.) is dissolved in 20 pts. cold sulphuric acid of 30 p.c. anhydride value and allowed to stand for 24 hours (Möhlau, *B.* 17, 1491). The absorption spectrum has been mapped by Hartley (*C. J.* 51, 192).

##### Di-methyl-amido-benzene-azo-benzoic acid

[4:1]  $\text{C}_6\text{H}_4\text{NMe}_2-\text{N}_2-\text{C}_6\text{H}_4\text{CO}_2\text{H}$  [1:3]. From di-methyl-aniline and *m*-diazobenzoic acid (Griess, *B.* 10, 525).

Di-methyl-amido-benzene-azo-di-methyl-aniline [1:4]  $\text{C}_6\text{H}_4(\text{NMe}_2)-\text{N}_2-\text{C}_6\text{H}_4\text{NMe}_2$  [1:4] [266°]. *Dimethylaniline-azylane*. Red needles.

Formation.—1. By diazotising *p*-amido-dimethyl-aniline and combining the diazo-compound  $\text{C}_6\text{H}_4(\text{NMe}_2)\text{N}_2\text{Cl}$  with dimethylaniline (Nöling, *B.* 18, 1143).—2. By passing NO through an alcoholic solution of di-methyl-aniline for several days.

Reactions.—1. Nitrous acid acting on the acetic acid solution gives *p*-nitro-di-methyl-aniline.—2. On reduction it gives *u*-di-methyl-*p*-phenylene-diamine.

**Salts.**— $B^+H_2Cl.PtCl_4$ : dichroic crystalline powder.—Picrate  $B^+C_6H_4(NO_2)_2.OH + C_6H_5.OH$ : glistening green needles (Lippmann a. Fleissner, *B.* 15, 2136; 16, 1415; *M.* 3, 708).

**Di-methyl-amido-benzene-azo-*p*-toluene**  
 $C_6H_3(N_2-C_6H_4.NMe_2)_2$  [168?]. Golden plates. Easily soluble in alcohol and ether.

**Preparation.**—A solution of 65 pts. of  $NaNO_2$  (100 p.c.) and 35 pts.  $NaOH$  in 465 pts. of water is slowly added to a cooled solution of 100 pts. of *p*-toluidine, 113 pts. of dimethylaniline and 200 pts. of  $HCl$  in 300 pts. of water.

On reduction it yields *p*-toluidine and dimethyl-*p*-phenylene-diamine. The hydrochloride and sulphate form violet prisms, giving a red solution in alcohol (Möhlau, *B.* 17, 1492).

**Di-methyl-amido-benzene-azo-*p*-toluene-sulphonic acid**  $C_6H_4(HSO_3)(N_2-C_6H_4.NMe_2)_2$ . Formed by the combination of *p*-diazo-toluene sulphonic acid ( $Me.HSO_3.N_2=1:3:4$ ) with dimethylaniline (Möhlau, *B.* 17, 1493). Dark-violet prisms. Soluble in water and alcohol with an orange colour, insoluble in ether. The sodium salt forms orange glistening plates.

**Di-methyl-amido-benzene-azo-toluidine**  
[4:1]  $C_6H_4(NMe_2)(N_2-C_6H_4.Me(NH_2))$  [1:6:3] [145?]. From its acetyl derivative [200?] which is formed by the action of diazotised-acetyl-tolylene-diamine  $C_6H_3(NH_2)Me(NHAc)$  [1:6:3] upon di-methyl-aniline (Wallach, *A.* 234, 355).

**Di-methyl-amido-benzene-azo-toluidine**  
[4:1]  $C_6H_4(NMe_2)(N_2-C_6H_4.Me(NH_2))$  [1:4:3] [215?]. From its acetyl derivative, [192?] which is formed by the action of diazotised acetyl-tolylene-diamine  $C_6H_3(NH_2)Me(NHAc)$  [1:4:3] upon di-methyl-aniline (Wallach, *A.* 234, 359).

***p*-Methyl-phenyl-amido-benzene-azo-methyl-di-phenyl-amine**

[4:1]  $C_6H_4.NMePh.N_2.C_6H_4.NMePh$  [1:4] [150?]. Yellow crystals, got by the action of  $NO$  on methyl-diphenyl-amine (Lippmann a. Fleissner, *M.* 4, 798).

**( $\alpha$ )-Naphthalene-( $\alpha$ )-azo-naphthalene**  
[ $\alpha$ ]  $C_{10}H_7.N_2.C_{10}H_7$ . [190?]. Prepared by boiling diazo-naphthalene-azo-naphthalene with alcohol: 1 pt. of naphthalene-azo-naphthylamine is dissolved in 100 pts. of 95 p.c. alcohol and 5 pts. of  $H_2SO_4$  are added; the still warm solution is then treated with a saturated solution of (1 mol. of)  $NaNO_2$ ; the fluid is heated and finally boiled for a few hours, and the azonaphthalene precipitated by water. It is recrystallised by dissolving it in hot aniline and adding alcohol (Nietzki a. Goll, *B.* 18, 298, 3252). Steel-blue crystals. Sublimes in thin yellow plates. Soluble in aniline, sparingly in alcohol. It dissolves in cold  $H_2SO_4$  with a blue colour, but on heating the solution to about  $180^\circ$  it becomes violet and exhibits a red fluorescence. By alcoholic  $NH_4HS$ , or zinc-dust and alcoholic  $KOH$ , it is reduced to hydrazonaphthalene.

**( $\alpha$ )-naphthalene-( $\beta$ )-azo-naphthalene**  
[ $\alpha$ ]  $C_{10}H_7.N_2.C_{10}H_7$  [8]. [136?]. Obtained by diazotisation of ( $\beta$ )-naphthalene-*p*-azo-( $\alpha$ )-naphthylamine and boiling with alcohol. Dark-brown plates with steel-blue reflex. Sol. alcohol, acetic acid, &c. Dissolves in conc.  $H_2SO_4$  with a violet colour (Nietzki a. Götting, *B.* 20, 612). Laurent's naphthase [275?], got by heating nitro-naphthalene with zinc dust, or ( $\alpha$ )-naphthylamine with  $PbO$ , has been regarded as naphtha-

lene-azo-naphthalene, but Witt has lately (*B.* 19, 2794) shown it to be an azine  $C_{10}H_7.N_2$ , v. ( $\alpha\beta$ )-NAPHTHAZINE (Laurent, *A.* 109, 384; Doer, *B.* 3, 291; Alexéeff, *B.* 3, 868; Schichuzky, *B.* 5, 365; Klobulowsky, *B.* 10, 670, 772, 878).

**Naphthalene-*p*-azo-( $\alpha$ )-naphthol**  
 $C_{10}H_7.N_2-C_{10}H_7.OH$ . Formed by adding diazo-naphthalene chloride to a solution of ( $\alpha$ )-naphthol in  $NaOH$  aq; it is pptd. by  $HCl$ . Crimson powder. Soluble in alkalis forming crimson solutions (P. F. Frankland, *C. J.* 37, 752).

**Naphthalene-o-azo-( $\beta$ )-naphthol**  
 $C_{10}H_7.N_2-C_{10}H_7.OH$ . [176?]. Formed by diazotising ( $\beta$ )-amido-azo-naphthalene and heating the diazo-compound with water (Nietzki a. Goll, *B.* 19, 1282). Sublimes in glistening golden needles.

**( $\alpha$ )-Naphthalene-( $\alpha$ )-azo-( $\alpha$ )-naphthylamine**  
 $C_{10}H_7.N_2-C_{10}H_7.NH_2$ . [180?]. Prepared by adding  $KNO_2$  (1 mol.) to a dilute solution of ( $\alpha$ )-naphthylamine hydrochloride (2 mol.) and making the mixture slightly alkaline with  $Na_2CO_3$  (Perkin a. Church, *A.* 129, 108; Nietzki a. Goll, *B.* 18, 298). Hartley (*C. J.* 51, 190) has mapped the absorption-spectrum. —  $B^+HCl$  —  $B^+HCl$  —  $B^+2HCl$  —  $B^+H_2SO_4$ .

**( $\beta$ )-Naphthalene-*p*-azo-( $\alpha$ )-naphthylamine**  
 $C_{10}H_7.N_2.C_{10}H_7.NH_2$  [152?]. Formed by mixing aqueous solutions of equal mols. of ( $\beta$ )-diazo-naphthalene chloride (from ( $\beta$ )-naphthylamine) and ( $\alpha$ )-naphthylamine hydrochloride. Yellowish-brown needles with green reflex (from alcohol). The base and its salts are far more soluble than the ( $\alpha$ )-azo-( $\alpha$ )-naphthalene.  $H_2SO_4$  dissolves it with a violet colour (Nietzki a. Götting, *B.* 20, 612).

**( $\beta$ )-Naphthalene-azo-( $\beta$ )-naphthylamine**  
 $C_{10}H_7$   $\begin{array}{c} NH \\ | \\ N_2H.C_6H_5 \end{array}$  or  $C_{10}H_7.N_2.C_{10}H_7.NH_2$  [149?].

Reddish-yellow needles. Easily soluble in benzene and acetic acid, insoluble in water. Formed by the action of amyl nitrite upon ( $\beta$ )-naphthylamine. The absorption-spectrum has been mapped by Hartley (*C. J.* 51, 191).

**Reactions.**—1. By heating with dilute  $H_2SO_4$  (20 p.c.) it is decomposed with evolution of nitrogen.—2. On reduction with  $SnCl_2$  it yields ( $\beta$ )-naphthylamine and (1:2)-naphthylenediamine.—3. Treated with bromine in alcoholic or acetic acid solution it is converted into di-bromo-( $\beta$ )-naphthylamine and a brominated  $\beta$ -naphthol. 4. May be diazotised in the following manner: 15 grms. of the amidoazonaphthalene are finally suspended in a mixture of 90 grms.  $H_2SO_4$  and 90 grms. of water, cooled with ice and slowly treated with a concentrated solution of 5 grms. sodium nitrite. The diazo-compound is very unstable (Nietzki a. Goll, *B.* 19, 1281).

**Acetyl derivative**  $C_{20}H_{11}N_4Ac$  [218?]; prisms; easily soluble in benzene, sparingly in alcohol and petroleum-spirit.

**Benzoyl derivative**  $C_{20}H_{11}N_4Bz$  [177?]; silky red needles; easily soluble in benzene, sparingly in alcohol and petroleum-spirit (Lawson, *B.* 18, 2422).

**( $\alpha$ )-Naphthalene-azo-*peri*-naphthylene-diamine**  $C_{10}H_7.N_2-C_{10}H_7(NH_2)_2$ . Prepared by the action of ( $\alpha$ )-diazonaphthalene chloride on *peri*-naphthylene-diamine (Stebbins, jun., *B.* 18,

717; *C. N.* 41, 117; *A. C. J.* 1, 445). Sol. alcohol, insol. water.— $\text{B'HCl}$ : sl. sol. water, m. sol. alcohol with a brown colour; dissolves in strong  $\text{H}_2\text{SO}_4$  with a blue colour.

( $\beta$ )-Naphthol-azo-naphthalene sulphonic acid  $\text{C}_{10}\text{H}_7(\text{OH})-\text{N}_2-\text{C}_{10}\text{H}_7\text{SO}_3\text{H}$ . From ( $\beta$ )-naphthol and ( $\alpha$ )-diazonaphthalene sulphonic acid (W. v. Miller, *B.* 13, 268).

( $\alpha$ )-Naphthol-*p*-azo-diphenyl sulphonic acid  $\text{C}_{10}\text{H}_7(\text{OH})-\text{N}_2-\text{C}_6\text{H}_4\text{SO}_3\text{H}$ . From ( $\alpha$ )-naphthol and *p*-diazodiphenyl sulphonic acid (Carnelley a. Schlevelmann, *C. J.* 49, 383).— $\text{NaA}'$ : dyes wool brown.— $\text{BaA}'$ .

( $\beta$ )-Naphthol-*p*-azo-diphenyl sulphonic acid  $\text{C}_{10}\text{H}_7(\text{OH})-\text{N}_2-\text{C}_6\text{H}_4\text{SO}_3\text{H}$ . From ( $\beta$ )-naphthol and *p*-diazodiphenyl sulphonic acid.— $\text{NaA}'$ : bright red pp., sl. sol. cold, v. sol. hot, water; dyes wool red.— $\text{BaA}'_2$  (Carnelley a. Schlevelmann, *C. J.* 49, 383).

*o*-Nitro-benzene-azo-aceto-acetic acid  $\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{CH}(\text{CO}_2\text{CH}_3)\cdot\text{CO}_2\text{H}$ . [185°]. Obtained by saponification of the ethyl-ether which is prepared by the action of *o*-nitro-diazobenzene chloride on an alkaline solution of aceto-acetic ether (Bamberger, *B.* 17, 2415). Glistening brown plates. V. sol. acetic acid and hot alcohol, v. sl. sol. ether and cold alcohol. On heating it evolves  $\text{CO}_2$  and yields *o*-nitro-benzene-azo-acetone  $\text{C}_6\text{H}_4(\text{NO}_2)\cdot\text{N}_2\cdot\text{CH}_2\cdot\text{CO}_2\text{CH}_3$ . The same decomposition is produced by heating with alkalis.

Salts.— $\text{A'NH}^+$ : yellow needles.— $\text{A'Ag}$ : crystalline pp.— $\text{A'Cu}^+$ : green pp., sol. hot water.— $\text{A'Ba}^+$ : yellow needles.— $\text{A'Hg}$ : glistening plates.

Ethyl ether  $\text{A'Et}$  [93°], glistening yellow plates or fine needles, sol. alcohol, ether, acetic acid, and hot water.

*o*-Nitro-benzene-azo-acetone  $\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{CH}_2\cdot\text{CO}_2\text{CH}_3$ . [124°]. Formed by heating *o*-nitro-benzene-azo-aceto-acetic acid to its melting-point, or by boiling the acid or its ether with alkalis.

Preparation.—*o*-Nitriline dissolved in absolute alcohol is diazotised by passing into the well-cooled solution a stream of  $\text{N}_2\text{O}_4$ , the product is poured into iced water, the solution filtered and mixed without cooling with a dilute solution of acetaacetic ether (1 mol.), and  $\text{KOH}$  (1 mol.), after mixing the fluid must be acid, it is digested at about 40° for 40 hours, the red pp. is then filtered off and purified (Bamberger, *B.* 17, 2418). Long silky yellow needles. Easily soluble in hot water, alcohol, ether, &c.

*o*-Nitro-benzene-azo-acetophenone  $[\text{2:1}] \text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{CH}(\text{CO}_2\text{C}_6\text{H}_5)$ . [141°].

Formed together with *o*-nitro-benzene-azobenzoyl-acetic ether, by adding a solution of *o*-nitro-diazobenzene chloride to an iced alkaline solution of benzoyl-acetic ether (Bamberger a. Calman, *B.* 18, 2565). Glistening yellow needles. Easily soluble in ordinary solvents.

*m*-Nitro-benzene-azo-aniline  $[\text{3:1}] \text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{N}_2\cdot\text{C}_6\text{H}_4\cdot\text{NH}_2$  [1:4]. [c. 210°]. From diazotised *m*-nitriline hydrochloride and aniline hydrochloride (Meldola, *C. J.* 45, 112).

$\alpha$ -Orange fern-like leaflets (from alcohol). Insol. in hot and dilute acids; forms yellow solutions in  $\text{C}_6\text{H}_6$ ,  $\text{CH}_2\text{Cl}_2$ , acetone, and benzene (Meldola, *C. J.* 45, 112). On reduction it gives *m*- and *p*-phenylene-pyrrol (see Salt.— $\text{B'HCl}$ ),  $\text{PtCl}_4$ , sodium.

**Nitro-benzene-azo-benzene sulphonic acid**  $[\text{3:1}] \text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{C}_6\text{H}_4\text{SO}_3\text{H}$  [1:4]. From benzene-azo-benzene sulphonic acid by nitration (Janovsky, *M.* 3, 505; 8, 60).— $\text{KA}$ .— $\text{BaA}'_2$ .— $\text{PbA}'_2$ .

**Nitro-benzene-azo-benzene sulphonic acid**  $[\text{4:1}] \text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{C}_6\text{H}_4\text{SO}_3\text{H}$  [1:4]. Formed, together with the less soluble isomeric just described, by heating benzene-azo-benzene *p*-sulphonic acid with nitric acid (S.G. 1:41). Leaflets.— $\text{KA}$  (Janovsky, *M.* 3, 506; 5, 157; *B.* 16, 1486). Ammonium sulphide reduces it to an amido-benzene-azo-benzene sulphonic acid which is different from that formed from diazotised sulphanilic acid and *p*-phenylene-diamine, although on complete reduction it gives sulphanilic acid and *p*-phenylene-diamine.

**Di-nitro-benzene-azo-benzene-sulphonic acid**  $[\text{3:4:1}] \text{C}_6\text{H}_3(\text{NO}_2)_2-\text{N}_2-\text{C}_6\text{H}_3\text{SO}_3\text{H}$  [1:4]. From either of the two preceding acids or from benzene-azo-benzene sulphonic acid and nitric acid (S.G. 1:45). Orange leaflets.— $\text{KA}$ .— $\text{BaA}'_2$ : S. 7 at 68° (Janovsky, *M.* 3, 507; 5, 157).

***o*-Nitro-benzene-azo-benzoyl-acetic acid**  $[\text{2:1}] \text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{CH}(\text{CO}_2\text{C}_6\text{H}_5)\cdot\text{CO}_2\text{H}$  [177°]. Its ethyl-ether is formed, together with *o*-nitro-benzene-azo-acetophenone, by adding a solution of *o*-nitro-diazobenzene chloride to an iced alkaline solution of benzoyl-acetic ether (Bamberger a. Calman, *B.* 18, 2565). Long, yellow silky needles. Sl. sol. alcohol and ether. By long heating at its melting-point it loses  $\text{CO}_2$  giving *o*-nitro-benzene-azo-acetophenone.

Oxim  $\text{C}_6\text{H}_4(\text{NO}_2)\cdot\text{N}_2(\text{CO}_2\text{H})\text{NOH}$  [142°]; orange-yellow needles.

*m*-Nitro-benzene-azo-*m*-chloro-di-methylaniline  $[\text{3:1}] \text{C}_6\text{H}_3(\text{NO}_2)\cdot\text{N}_2\cdot\text{C}_6\text{H}_3\text{Cl}_2\text{NMe}_2$  [12:4] [156°]. Prepared by adding sodium nitrite (1 mol.) to a solution of *m*-nitriline (1 mol.) and *m*-chloro-di-methylaniline (1 mol.) in dilute  $\text{H}_2\text{SO}_4$  (Staedel a. Bauer, *B.* 19, 1956). Reddish-yellow plates (from alcohol).

*p*-Nitro-benzene-azo-di-methylaniline  $[\text{4:1}] \text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{N}_2\cdot\text{C}_6\text{H}_4\text{NMe}_2$  [1:4]. [230°]. The hydrochloride is deposited as crystals with steel-blue reflex when aqueous diazo-*p*-nitro-benzene chloride is added to aqueous dimethylaniline hydrochloride (Meldola, *C. J.* 45, 107).

Properties.—Chocolate-brown powder, slightly soluble in alcohol whence it separates as brown needles. Solutions are orange in benzene and in glacial acetic acid, orange in conc.  $\text{H}_2\text{SO}_4$ , red on dilution. Salt.— $\text{B'HCl}$ ,  $\text{PtCl}_4$ .

*m*-Nitro-benzene-*p*-azo-dimethylaniline  $[\text{3:1}] \text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{N}_2\cdot\text{C}_6\text{H}_4\text{NMe}_2$  [1:4]. [159°]. From  $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{N}_2\text{Cl}$  and  $\text{C}_6\text{H}_4\text{NMe}_2\text{HCl}$  (Meldola, *C. J.* 45, 120; Staedel a. Bauer, *B.* 19, 1954). Orange crystalline powder. Solutions in alcohol, benzene, acetone, and glacial acetic acid, are yellowish-orange; in conc.  $\text{H}_2\text{SO}_4$ , pale orange, turned red by dilution. After reduction by  $\text{HCl}$  and zinc-dust,  $\text{Fe}_2\text{Cl}_6$  forms a blue dye.

*m*-Nitro-benzene-azo-( $\alpha$ )-naphthol  $[\text{3:1}] \text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{C}_{10}\text{H}_7\text{OH}$  [1:4]. From *m*-diazonitrobenzene and ( $\alpha$ )-naphthol (Stebbins, jun., *A. C. J.* 2, 446). Brown pp., sol. water.

*p*-Nitro-benzene-azo-( $\alpha$ )-naphthol  $[\text{4:1}] \text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{C}_{10}\text{H}_7\text{OH}$  [1:4]. From *p*-diazonitrobenzene chloride and an alkaline solution of ( $\alpha$ )-naphthol (Meldola, *C. J.* 47, 661). Dull red powder, melts above 360°. V. sl. sol.

illing alcohol.  $\text{H}_2\text{SO}_4$  forms a violet solution; of NaOH aq gives a blue colour.

*m*-Nitro-benzene-azo-( $\beta$ )-naphthol

[3:1]  $\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{C}_{10}\text{H}_7\text{OH}$  [1:2] or

$\text{H}_2\text{N}-\text{C}_6\text{H}_4-\text{N}_2-\text{C}_{10}\text{H}_7\text{OH}$  [194°]. From *m*-diazotro-benzene chloride and an alkaline solution

( $\beta$ )-naphthol (Meldola, *C. J.* 47, 668). Lustrous range scales (from toluene). Insol. aqueous alkalis; sol. alcoholic KOH.  $\text{H}_2\text{SO}_4$  gives a magenta red solution. It is not reduced by ammonium sulphide.

*p*-Nitro-benzene-azo-( $\beta$ )-naphthol

[4:1]  $\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{C}_{10}\text{H}_7\text{OH}$  (?) [1:2]. [249°]. From *p*-diazotro-benzene chloride and sodium ( $\beta$ )-naphthol (Meldola, *C. J.* 47, 663). Orange needles. Insol. hot NaOH aq. Conc.  $\text{H}_2\text{SO}_4$  gives a magenta-red solution.

*m*-Nitro-benzene-azo-( $\beta$ )-naphthol-disulphonic acid [3:1]  $\text{C}_6\text{H}_3(\text{NO}_2)\text{N}_2\text{C}_{10}\text{H}_6(\text{SO}_3\text{H})_2(\text{OH})$  (?). Prepared by acting on di-azo-*m*-nitro-benzene with ( $\beta$ )-naphthol disulphonic acid in alkaline solution. V. sol. water; dyes an old gold colour (Stebbins, jun., *A. C. J.* 2, 446).

*m*-Nitro-benzene-( $\alpha$ )-azo-( $\alpha$ )-naphthylamine

[3:1]  $\text{NO}_2\text{C}_6\text{H}_4-\text{N}_2-\text{C}_{10}\text{H}_7\text{NH}_2$  [1:4]. [203°]. From  $\text{NO}_2\text{C}_6\text{H}_4\text{NH}_2$  and  $\text{C}_{10}\text{H}_7\text{NH}_2\text{HCl}$  (Meldola, *C. J.* 45, 114).

*Properties*.—Red needles. Solutions in alcohol, acetone, and benzene, are orange; in acetic acid, red; in conc.  $\text{H}_2\text{SO}_4$ , violet-red turned red by dilution. Completely decomposed by ammonium sulphide.

*p*-Nitro-benzene-azo-( $\alpha$ )-naphthylamine

[4:1]  $\text{NO}_2\text{C}_6\text{H}_4\text{N}_2\text{C}_{10}\text{H}_7\text{NH}_2$  [1:4]. [252°]. From aqueous *p*-nitro-diazo-benzene chloride and alcoholic ( $\alpha$ )-naphthylamine hydrochloride (Meldola, *C. J.* 43, 430). Brown needles (from benzene). Forms a crimson alcoholic solution. (B'HC1).  $\text{PtCl}_4$ . Salts hardly soluble in alcohol.

*Reactions*.—Reduces to *p*-phenylene-diamine and ( $\alpha,\alpha$ ) naphthylene-diamine.

*m*-Nitro-benzene-azo-( $\beta$ )-naphthylamine

[3:1]  $\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{C}_{10}\text{H}_7\text{NH}_2$  or  $\text{NH}_2-\text{C}_{10}\text{H}_7-\text{N}_2-\text{C}_6\text{H}_4(\text{NO}_2)$  [177°]. From

$\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2\text{H}$  and ( $\beta$ )-naphthylamine. Splendid orange needles. Solutions in toluene, chloroform, and glacial acetic acid, are orange; in alcohol and in acetone, orange but turned red by HCl; in conc.  $\text{H}_2\text{SO}_4$ , violet (Meldola, *C. J.* 45, 117).

*p*-Nitro-benzene-azo-( $\beta$ )-naphthylamine

[4:1]  $\text{NO}_2\text{C}_6\text{H}_4-\text{N}_2-\text{C}_{10}\text{H}_7\text{NH}_2$  (?) [1:2]. [180°]. From aqueous *p*-nitro-diazo-benzene chloride and aqueous ( $\beta$ )-naphthylamine hydrochloride (Meldola, *C. J.* 43, 420). Needles, with golden lustre (from alcohol). Its solutions in alcohol, acetone, and chloroform are red, in benzene and toluene, orange, in conc.  $\text{H}_2\text{SO}_4$ , violet. Its salts are readily soluble in alcohol. (B'HC1).  $\text{PtCl}_4$ .

*p*-Nitro-benzene-azo-*p*-nitro-benzene

[4:1]  $\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{C}_6\text{H}_4(\text{NO}_2)$  [1:4]. *Di-nitro-azo-benzene*. [201°]. Formed by nitration of benzene-azo-benzene (Laurent a. Gerhardt, *A.* 75, 73; Janovsky, *M.* 6, 159; 7, 135; *B.* 18, 1134). Red crystals (from glacial HOAc). Gives, when reduced by ammonium sulphide, a nitrolic

VOL. I.

acid ( $\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{C}_6\text{H}_4(\text{NOH})$ ) (?) [181°] of which the sodium salt is blue. It is re-oxidized by  $\text{K}_2\text{FeO}_4$  to *p*-nitro-benzene-azo-*p*-nitro-benzene.

*m*-Nitro-benzene-azo-*m*-nitro-benzene

[3:1]  $\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{C}_6\text{H}_4(\text{NO}_2)$  [1:3]. A red oil, formed in the preparation of the preceding (Janovsky, *M.* 6, 455). Ammonium sulphide and NaOH give a violet colour.

*o*-Nitro-benzene-*p*-azo-nitro-benzene

[2:1]  $\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{C}_6\text{H}_4(\text{NO}_2)$  [1:4]. [208°]. From nitro-benzene- $\delta$ -azo-nitro-benzene (Janovsky, *M.* 7, 131). Orange laminae. Alcoholic ammonium sulphide mixed with NaOH aq gives a permanent blue.

Nitro-benzene-azo-nitro-benzene

$\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{C}_6\text{H}_4(\text{NO}_2)$  [1:4]. [205°]. A by-product in the nitration of benzene-azo-benzene-*p*-sulphonic acid (Janovsky, *M.* 7, 132). Orange laminae. Ammonium sulphide and NaOH gives a permanent blue nitrolic.

Nitro-benzene-azo-nitro-benzene

$\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{C}_6\text{H}_4(\text{NO}_2)$  [180°]. A product of nitration of benzene-azo-benzene (Janovsky, *M.* 7, 134). Pale, asbestos-like, needles. Ammonium sulphide and NaOH give a blue nitrolic changing to brown.

Nitro-benzene-azo-di-nitro-benzene

[4:1]  $\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{C}_6\text{H}_3(\text{NO}_2)_2$  [1:2:3 or 5 or 6] or [1:3:5]. [112°]. Formed by nitration of benzene-azo-benzene (Petrie, *Z.* [2] 6, 564) or benzene-azo-*p*-nitro-benzene (Janovsky, *M.* 7, 125). Yellow needles. Boiling with a mixture of alcoholic NaOH and aqueous ammonium sulphide gives a green colour, changing to brown.

Nitro-benzene-azo-di-nitro-benzene

[3:1]  $\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{C}_6\text{H}_3(\text{NO}_2)_2$  [1:3:4]. [170°]. Formed by nitration of benzene-*p*-azo-nitro-benzene or *m*-nitro-benzene-*m*-azo-nitro-benzene (Janovsky, *M.* 7, 126). Yellow tablets. Alcoholic ammonium sulphide and aqueous NaOH give an olive-green colour, turning brown.

Nitro-benzene-azo-di-nitro-benzene

[3:1]  $\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{C}_6\text{H}_3(\text{NO}_2)_2$  [1:3:2 or 5 or 6]. [124°]. Formed by nitrating *m*-nitro-benzene-*m*-azo-nitro-benzene (J.). Yellow prisms. Nitrolic reaction: emerald-green changing to orange.

Nitro-benzene-azo-di-nitro-benzene

[4:1]  $\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{C}_6\text{H}_3(\text{NO}_2)_2$  [1:4:3 or 2]. [185°]. Formed by nitrating *p*-nitro-benzene-*p*-azo-nitro-benzene or benzene-azo-benzene (Janovsky, *M.* 6, 461; *B.* 18, 1135). Needles.

Nitro-benzene-azo-di-nitro-benzene

[4:1]  $\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{C}_6\text{H}_3(\text{NO}_2)_2$  [1:4:2 or 3]. [160°]. Formed in the preparation of the preceding substance (Janovsky, *M.* 6, 462; 7, 125; *B.* 18, 1134). Yellow needles (from alcohol). Nitrolic reaction: green, turning blue. This body and the preceding, both give (1, 2, 4)-tri-amido-benzene and *p*-phenyl-*ne*-diamine on reduction.

Nitro-benzene-azo-nitro-ethane

[3:1]  $\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{CH}(\text{NO}_2)\text{CH}_3$ . From potassium nitro-ethane and *m*-diazotro-benzene nitrate (Hallmann, *B.* 9, 391). Yellow powder. Reduced by tin and HCl to the tin salt  $\text{B}^3\text{H}_2\text{SnCl}_4$  of an unstable base di-amido-phenyl-ethyl-hydrazine  $\text{C}_6\text{H}_4(\text{NH}_2)-\text{N}_2\text{H}_2-\text{CH}(\text{NH}_2)\text{CH}_3$ .

Nitro-benzene-azo-nitro-phenol

[3:1]  $\text{C}_6\text{H}_3(\text{NO}_2)_2-\text{N}_2-\text{C}_6\text{H}_4(\text{NO}_2)(\text{OH})$  [1:3:1]. [173°]. Formed by heating the isomeric di-*m*-nitro-azoxy-benzene  $\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2\text{O}-\text{C}_6\text{H}_4(\text{NO}_2)$  C C

with strong  $\text{H}_2\text{SO}_4$  for some time to about  $140^\circ$  (Klinger & Pitschke, *B. 18*, 2552). Yellowish-brown crystals. Dissolves in alkalis with an orange colour.—A'Ag: red crystalline pp.

***p*-Nitro-benzene-azo-o-oxy-benzoic acid**  
[4:1]  $\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{C}_6\text{H}_3(\text{CO}_2\text{H})(\text{OH})$  [1:3:4]. From diazotised *p*-nitro-aniline and a cooled alkaline solution of salicylic acid (Meldola, *C. J.* 47, 666). Brown needles (from dilute acetic acid); sol. alkalis.  $\text{H}_2\text{SO}_4$  gives an orange solution. Blackens at  $225^\circ$ .

***p*-Nitro-benzene-azo-phenol**  
[4:1]  $\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{C}_6\text{H}_4(\text{OH})$  [1:4]. [184°]. From diazotised *p*-nitro-aniline and sodium phenol (Meldola, *C. J.* 47, 658). Golden scales; v. sl. sol. water; sol. boiling dilute alkalis.  $\text{H}_2\text{SO}_4$  gives an orange solution.

***m*-Nitro-benzene-*p*-azo-diphenylamine**  
[3:1]  $(\text{NO}_2)\text{C}_6\text{H}_4-\text{N}_2-\text{C}_6\text{H}_4(\text{NHC}_6\text{H}_5)_2$  [1:4]. [137°]. From  $\text{NO}_2\text{C}_6\text{H}_4\text{N}_2\text{Cl}$  and  $\text{NH}(\text{C}_6\text{H}_5)_2$  (Meldola, *C. J.* 45, 118). Reddish-brown scales (from dilute alcohol). Solutions in alcohol, acetone, glacial acetic acid, and benzene are orange. On adding  $\text{HCl}$  to the alcoholic solution the liquid turns crimson, and, if concentrated, a brown gelatinous hydrochloride is ppd. Conc.  $\text{H}_2\text{SO}_4$  forms a violet solution. After reduction by  $\text{Zn}$  and  $\text{HCl}$ ,  $\text{FeCl}_3$  forms a blue dye. Its salts are unstable.

**Nitroso derivative** [128°].

***p*-Nitro-benzene-azo-di-phenylamine**  
[4:1]  $(\text{NO}_2)\text{C}_6\text{H}_4-\text{N}_2-\text{C}_6\text{H}_4(\text{NHC}_6\text{H}_5)_2$  [1:4] [151°]. From aqueous diazotised *p*-nitraniline and alcoholic diphenylamine. The pp. is treated with ammonium carbonate, and the base crystallised from dilute alcohol (Meldola, *C. J.* 43, 440). Brown leaflets. Solutions are orange in alcohol, turned violet by  $\text{HCl}$ ; violet in conc.  $\text{H}_2\text{SO}_4$ . The hydrochloride forms needles, with violet reflex, but is very unstable.

***p*-Nitro-benzene-azo-resorcin**  
[4:1]  $\text{C}_6\text{H}_4(\text{NO}_2)-\text{N}_2-\text{C}_6\text{H}_3(\text{OH})_2$  [1:2:4]. From *p*-diazonitro-benzene nitrate and resorcin in alkaline solution (Meldola, *C. J.* 47, 660). Brick-red crystalline powder;  $\text{KOH}$  forms a violet,  $\text{H}_2\text{SO}_4$  an orange, solution.

***p*-Nitro-benzene-azo-*m*-xylydine**  
[4:1]  $(\text{NO}_2)\text{C}_6\text{H}_4-\text{N}_2-\text{C}_6\text{H}_3\text{Me}_2(\text{NH}_2)$  [1:3:5:2]. [141°]. From aqueous *p*-nitro-diazo-benzene chloride and alcoholic *m*-xylydine hydrochloride (Meldola, *C. J.* 43, 428). There results a bulky reddish pp. of  $\text{NO}_2\text{C}_6\text{H}_4\text{N}_2\text{NHC}_6\text{H}_3\text{Me}_2$ , which, on standing, changes to the scarlet hydrochloride of the azo-compound.

**Properties.**—Brick-red needles (from dilute alcohol). Forms orange solutions in alcohol, acetone, benzene, chloroform, and conc.  $\text{H}_2\text{SO}_4$ .

**Salts.**—The chloride, sulphate, and nitrate form red needles with violet reflex, insoluble in alcohol.—( $\text{B'}$  $\text{HCl}$ )  $\text{PtCl}_4$ .

**Nitro-carboxy-benzene-azo-nitro-benzoic acid**  
 $\text{N}_2(\text{C}_6\text{H}_3(\text{NO}_2)(\text{CO}_2\text{H}))_2$  (?). Formed by nitrating carboxy-benzene-azo-benzoic acid (Golubeff, *J. R.* 6, 197).— $\text{NaA''}$ .— $\text{KA''}$  3aq.— $\text{BaA''}$ .— $\text{EtA''}$ : [104°].

**Di-nitro-oxy-amido-benzene-azo-xylene**  
 $\text{C}_6\text{H}_3(\text{NO}_2)_2(\text{NH}_2)(\text{OH})-\text{N}_2-\text{C}_6\text{H}_4\text{Me}_2$ . From diazo-xylene chloride and di-nitro-amido-phenol in alkaline solution (Stebbins, jun., *A. C. J.* 2, 236). Brown powder, sl. sol. cold water.

**Nitro-oxy-benzene-azo-benzene sulphonic acid** [3:4:1]  $\text{C}_6\text{H}_3(\text{NO}_2)(\text{OH})-\text{N}_2-\text{C}_6\text{H}_4\text{SO}_3\text{H}$  [1:4]. From diazotised sulphanilic acid and *o*-nitro-phenol (Griess, *B. 11*, 2195; R. Meyer & A. Kreis, *B. 16*, 1331).

**Nitro - oxy - benzene - azo - naphthalene sulphonic acid**  $\text{C}_6\text{H}_3(\text{NO}_2)(\text{OH})-\text{N}_2-\text{C}_{10}\text{H}_7\text{SO}_3\text{H}$ . From diazotised (*a*)-naphthylamine sulphonic acid and *o*-nitro-phenol (Stebbins, jun., *A. C. J.* 2, 236). Red needles, v. sol. water.

**Di-nitro-oxy-benzene-azo-naphthylamine sulphonic acid**  $\text{C}_6\text{H}_3(\text{NO}_2)_2(\text{OH})-\text{N}_2-\text{C}_{10}\text{H}_7(\text{NH}_2)\text{SO}_3\text{H}$ . From diazo-di-nitro-phenol and (*a*)-naphthylamine sulphonic acid (Stebbins, jun., *A. C. J.* 2, 446). Reddish-brown dye; sol. water.

**Nitro-oxy-benzene-azo-nitro-phenol.**

**Ethyl ether**

[2:2:1]  $\text{C}_6\text{H}_3(\text{OEt})(\text{NO}_2)-\text{N}_2-\text{C}_6\text{H}_4(\text{OEt})(\text{NO}_2)$  [1:2:2]. [190°]. Formed by nitrating *o*-oxy-benzene-*o*-azo-phenol ethyl ether, and separated from the isomeric compound by alcohol, in which it dissolves (Andreae, *J. pr.* [2] 21, 322). Needles (from alcohol).

**Nitro-oxy-benzene-azo-nitro-phenol.**

**Ethyl ether**

[2:2:1]  $\text{C}_6\text{H}_3(\text{OEt})(\text{NO}_2)-\text{N}_2-\text{C}_6\text{H}_4(\text{OEt})(\text{NO}_2)$  [1:2:2]. [235°]. Formed together with the preceding (*q. v.*). Brownish-red crystals (from chloroform). Insol. alcohol. Dissolves without change in conc.  $\text{H}_2\text{SO}_4$ . Reduced by alcoholic ammonium sulphide to the di-ethyl ether of dinitro-dioxy-di-phenylhydrazine.

**Di-nitro-oxy-benzene-azo-phenol sulphonic acid**  $\text{C}_6\text{H}_3(\text{NO}_2)_2(\text{OH})-\text{N}_2-\text{C}_6\text{H}_4(\text{OH})\text{SO}_3\text{H}$ . From diazotised di-nitro-amido-phenol and an alkaline solution of phenol *o*-sulphonic acid (Stebbins, jun., *A. C. J.* 2, 236; *C. N.* 42, 44). Brown lustrous needles, sl. sol. hot water.

**Nitro-diphenyl-azo-nitro-diphenyl (?)**

[4:1]  $\text{C}_6\text{H}_4(\text{NO}_2)\text{C}_6\text{H}_4-\text{N}_2-\text{C}_6\text{H}_4\text{C}_6\text{H}_4(\text{NO}_2)$  [1:4]. [187°]. From *p*-dinitro-diphenyl and sodium amalgam (Wald, *B. 10*, 137). Yellow powder (from alcohol).

***m*-Nitro-toluene-azo-aceto-acetic acid**

[4:2:1]  $\text{C}_6\text{H}_3(\text{CH}_3)(\text{NO}_2)-\text{N}_2-\text{CH}(\text{CO}_2\text{CH}_3)\text{CO}_2\text{H}$  [176°]. Obtained by saponification of the ethyl-ether formed by the action of nitro-diazo-toluene chloride (from nitro-*p*-toluidine [114°]) on an alkaline solution of aceto-acetic ether (Bamberger, *B. 17*, 2421). Long yellow silky needles. V. sol. hot alcohol and  $\text{HOAc}$ .—A'Ba.

***m*-Nitro-toluene-azo-acetone**

[4:2:1]  $\text{C}_6\text{H}_3(\text{CH}_3)(\text{NO}_2)-\text{N}_2-\text{CH}_2\text{CO}_2\text{CH}_3$  [134°]. Formed by the action of a dilute solution of aceto-acetic ether (1 mol.) and  $\text{KOH}$  (1 mol.) on a solution of nitro-diazo-toluene nitrate (from nitro-*p*-toluidine [114°]) (Bamberger, *B. 17*, 2421). Orange-red prisms. V. sol. alcohol and ether.

***m*-Nitro-toluene-azo-acetophenone**

[4:2:1]  $\text{C}_6\text{H}_3(\text{CH}_3)(\text{NO}_2)-\text{N}_2-\text{CH}_2\text{CO}_2\text{C}_6\text{H}_5$ . [168°]. Glistening yellow needles. Formed, together with nitro-toluene-azo-benzoyl-acetic ether, by adding a solution of nitro-diazo-toluene chloride (from *m*-nitro-*p*-toluidine [114°]) to an acid alkaline solution of benzoyl-acetic ether.

**Ketozim**  $\text{C}_6\text{H}_3\text{N}_2(\text{NO}_2)::\text{NOH}$  [174°]; orange needles (Bamberger & Calman, *B. 18*, 2566).

***m*-Nitro-*p*-toluene-azo-benzoyl-acetic acid**

[4:2:1]  $\text{C}_6\text{H}_3(\text{CH}_3)(\text{NO}_2)-\text{N}_2-\text{CH}(\text{CO}_2\text{C}_6\text{H}_5)\text{CO}_2\text{H}$  [194°]. Its ethyl-ether is formed, together with

*m*-nitro-*p*-toluene-azo-acetophenone, by adding a solution of *m*-nitro-*p*-diazo-toluene chloride to an iced alkaline solution of benzoyl-acetic ether (Bamberger a. Calman, *B.* 18, 2566). Silky yellow needles. V. sl. sol. cold alcohol and acetic acid, more easily at the boiling-point.

*p*-Oxy-benzene-azo-benzene-*m*-sulphonic acid [4:1]  $C_6H_4(OH) \cdot N_2 \cdot C_6H_4SO_3H$  [1:3]. From diazotised amido-benzene *m*-sulphonic acid and an alkaline solution of phenol. Leaflets, with violet reflex; insol. ether, v. sol. water and alcohol. —KA': long needles (Griess, *B.* 11, 2191).

*p*-Oxy-benzene-azo-benzene-*p*-sulphonic acid [4:1]  $C_6H_4(HSO_3) \cdot N_2 \cdot C_6H_4(OH)$  [1:4]. *Tropaeoline* Y. Prepared by the action of an aqueous alkaline solution of phenol on *p*-diazobenzene sulphonic acid (Griess, *B.* 11, 2192). Yellowish red prisms. V. sol. water and alcohol.

Salts. —BaA': orange pp. —BaA', 2aq. —BaA', 5aq: minute orange tables, sl. sol. water. —KA': yellow rhombic leaflets, S. 26 at 15° (Wilsing, *A.* 215, 232).

*p*-Oxy-benzene-azo-benzene sulphonic acid [4:1]  $C_6H_4(OH) \cdot N_2 \cdot C_6H_4SO_3H$ . From azoxy-benzene (1 pt.) and fuming  $H_2SO_4$  (5 pts.) at 110° (Limpficht, *B.* 15, 1295; Wilsing, *A.* 215, 229); Tschirwinsky (*J.* R. 5, 217) considers this acid to be identical with the preceding. Small lustrous reddish plates, v. sol. water, m. sol. dilute acids or alcohol. Br does not act on the potassium salt.  $SnCl_2$  forms no aniline by reduction. Salts. —KA' aq: S. 35 at 15°. —BaA', 2aq. —MgA', 2aq. —CuA', 2aq.

*Chloride*. [122°]. Orange 6- or 8-sided plates.

*Amide*. [212°]. Plates.

*Di*-oxy-benzene-azo-benzene sulphonic acid [4:2:1]  $C_6H_4(OH)_2 \cdot N_2 \cdot C_6H_4SO_3H$  [1:4]. *Tropaeolin* O. *Chrysoine*. Formed by sulphonating benzene-azo-resorcin at 100° (Witt, *C. J.* 35, 183) or from diazotised amido-benzene *p*-sulphonic acid and resorcin dissolved in KOHAq (Griess, *B.* 11, 2195). Red leaflets with steel-blue reflex; v. sl. sol. alcohol and cold water. —KA'. —BaA', 4aq.

The absorption-spectrum has been examined by Hartley (*C. J.* 51, 182).

*Di*-oxy-benzene-azo-benzene *m*-sulphonic acid [4:2:1]  $C_6H_4(OH)_2 \cdot N_2 \cdot C_6H_4SO_3H$  [1:3]. From resorcin and diazotised amido-benzene *m*-sulphonic acid. Orange needles. —KA': hygroscopic needles.

*Tri*-oxy-benzene-azo-benzene sulphonic acid [2:4:6:1]  $C_6H_3(OH)_3 \cdot N_2 \cdot C_6H_4SO_3H$  [1:4]. From diazotised amido-benzene *p*-sulphonic acid and an alkaline solution of phloroglucin (Stebbins, *C. N.* 42, 44; *A. C. J.* 1, 465; 2, 236; *B.* 13, 716). Yellow leaflets with green lustre. —NaA': yellow leaflets, easily soluble in water.

*p*-Oxy-benzene-*m*-azo-benzoic acid [4:1]  $C_6H_4(OH) \cdot N_2 \cdot C_6H_4CO_2H$  [1:3]. [220°]. *Formation*. —1. From *m*-diazo-benzoic acid and phenol (Griess, *B.* 14, 2032). —2. By gently warming *m*-carboxy-diazo-benzene-*m*-carboxy-anilide  $C_6H_4(CO_2H)_2 \cdot NH \cdot C_6H_4(CO_2H)$  with phenol, *m*-amido-benzoic acid being eliminated (Heumann a. Oeconomides, *B.* 20, 906). Red needles or plates; sl. alcohol and ether, sl. sol. water. Dyes wool and silk yellow. —BaA', 3½aq.

*Di*-oxy-benzene-*m*-azo-benzoic acid [4:2:1]  $C_6H_4(OH)_2 \cdot N_2 \cdot C_6H_4CO_2H$  [1:3]. Pre-

pared by the action of *m*-diazobenzoic acid on an alkaline solution of resorcin (Griess, *B.* 14, 2034). Brownish-red needles or brownish-yellow plates. Sol. alcohol. Dyes wool and silk yellow.

*Oxy*-benzene-azo-*p*-cresol. *Ethyl ether* [4:1]  $C_6H_4(OEt) \cdot N_2 \cdot C_6H_4(CH_3)(OH)$  [1:5:2]

or  $C_6H_4Me \cdot \begin{array}{c} O \\ | \\ N_2 \cdot H \cdot C_6H_4Me \cdot (OEt) \end{array}$ . [104°]. Formed

by combining *p*-diazophenol with *p*-cresol (Liebermann a. Kostanecki, *B.* 17, 883). Golden plates. Sol. alkalis. Dissolves in  $H_2SO_4$  with a brown colour. On reduction it gives *p*-amido-phenetol and amido-*p*-cresol.

*o*-Oxy-benzene-azo-*o*-cresol. *Methyl ether*  $C_6H_4(OMe) \cdot N_2 \cdot C_6H_4Me(OH)$ . [68°]. From diazotised *o*-anisidine and *o*-cresol (Kanonnikoff, *J. R.* 1885, 369). *Di*-methyl ether [103°].

*o*-Oxy-benzene-azo-*m*-cresol. *Methyl ether*. [161°]. Prepared like the preceding (K.).

*Di*-oxy-benzene-azo-*ψ*-cumene

[4:2:1]  $C_6H_4(OH)_2 \cdot N_2 \cdot C_6H_4Me_3$  [199°]. Formed, together with the disazo-compound, by combining diazo-cumene chloride (from amido-pseudo-cumene (62°)) with resorcin (Liebermann a. Kostanecki, *B.* 17, 131, 882). Small red needles. Dissolves in alkalis with a brownish-yellow colour.

*Di*-oxy-benzene-azo-hydroquinone

[5:2:1]  $C_6H_4(OH)_2 \cdot N_2 \cdot C_6H_4(OH)_2$  [1:2:5]. *Aso*-hydroquinone. *Tetra-methyl derivative*  $C_6H_4(OMe)_2 \cdot N_2 \cdot C_6H_4(OMe)_2$ . [140°]. Formed by reduction of nitro-di-methyl-hydroquinone in alkaline solution (Baessler, *B.* 17, 2124; *C. C.* 1886, 671). Red needles. V. sol. alcohol, benzene, chloroform, and  $CS_2$ , v. sl. sol. water. Dissolves in strong HCl with a blue colour.

*Tetra-ethyl derivative* [128°].

From nitro-di-ethyl-hydroquinone, powdered zinc, and alcoholic potash (Nietzki, *B.* 12, 39).

*Di*-oxy-benzene-azo-naphthalene sulphonic acid [4:2:1]  $C_6H_4(OH)_2 \cdot N_2 \cdot C_{10}H_6SO_3H$  [1:4]. From diazotised (α)-naphthylamine sulphonic acid and an alkaline solution of resorcin (Stebbins, jun., *A. C. J.* 2, 36; *C. N.* 42, 44). Dark-brown needles, sol. water.

*p*-Oxy-benzene-azo-(α)-naphthylamine

[4:1]  $C_6H_4(OH) \cdot N_2 \cdot C_{10}H_6NH_2$  [1:4]. [170°]. Prepared by the action of *p*-diazophenol nitrate on (α)-naphthylamine (Weselsky a. Benedikt, *B.* 12, 229). Orange needles (containing 3aq). —B',  $H_2SO_4$ , 6aq: green needles, insol. water.

*o*-Oxy-benzene-azo-(β)-naphthylamine

[2:1]  $C_6H_4(OH) \cdot N_2 \cdot C_{10}H_6$  or  $C_{10}H_6 \cdot \begin{array}{c} NH \\ | \\ N_2 \cdot H \cdot C_6H_4OH \end{array}$

*o*-Oxy-benzene-hydrazimido-naphthalene. [139°]. Formed by combining *o*-diazophenol with (β)-naphthylamine. Slender red needles (from alcohol or acetic acid), or dark red plates (from benzene). It dissolves in aqueous or alcoholic NaOH, but is insoluble in water. By heating at 150° with HCl it is split up into (β)-naphthylamine, pyrocatechin, and nitrogen. Bromine in cold acetic acid solution gives di-bromo-(β)-naphthylamine, a brominated pyrocatechin, and nitrogen. On reduction with zinc dust and acetic acid it yields (1:2)-naphthylene-diamine.

*Acetyl derivative* [198°].

*Benzoyl derivative* [183°].

**Methyl ether**  $C_6H_4(OMe).N_2C_6H_5$  [188°]; dark-red monoclinic prisms; insoluble in water (Sachs, B. 18, 3125).

**p-Oxy-benzene-azo-( $\beta$ )-naphthylamine**

[4:1]  $C_{12}H_9(OH).N_2C_{10}H_7$  or  $C_{10}H_7$    $N_2H_5C_6H_4OH$ .

**p-Oxy-benzene-hydrazimido-naphthalene** [193°]. Formed by combining *p*-dialzo-phenol with ( $\beta$ )-naphthylamine. Flat red prisms. V. sol. benzene and acetic acid, insol. water. By heating at 150° with HCl it is split up into ( $\beta$ )-naphthylamine, hydroquinone, and nitrogen. Bromine in cold acetic acid solution gives di-bromo-( $\beta$ )-naphthylamine, a brominated hydroquinone, and nitrogen. On reduction with zinc dust and acetic acid it yields (1:2)-naphthylene-diamine (Sachs, B. 18, 3125).

**Mono-acetyl derivative** [218°].

**Mono-benzoyl derivative** [214°].

**Oxy-benzene-azo-orein. Methyl ether**

$C_6H_4(OMe).N_2C_6H_4(OH).Me$ . Hair-like needles (Stebbins, A. C. J. 5, 32).

**o-Oxy-benzene-azo-phenol**

[2:1]  $C_6H_4(OH).N_2C_6H_4(OH)$  [1:2]. **o-Azo-phenol** [171°]. S. (alcohol) -3 at 20°. Prepared by fusing *o*-nitro-phenol with KOH (Weselsky a. Benedikt, B. 11, 398; A. 196, 344). Golden leaflets; may be sublimed. Insol. water.

**Reactions.**—1. Bromine added to an ethereal solution forms a tetra-bromo-derivative. 2. Chlorine passed into an acetic acid solution forms a tri-chloro derivative  $C_6H_3Cl_3(OH).N_2$  [235°] (Bohn a. Hermann, B. 17, 275).—3. Nitric acid forms (1, 2, 4)-di-nitro-phenol.

**Ethyl ether**  $\{C_6H_4(OEt)_2\}_n$  [131°].

*o*-Nitro-phenyl-ethyl ether  $C_6H_4(OEt)(NO_2)$  is dissolved in alcohol and reduced with sodium-amalgam (5 per cent.), the liquid being allowed to become hot. The product is poured into water, and the pp. extracted by strong HCl which dissolves the azo-compound. On pouring the HCl solution into water, *o*-azo-phenol is thrown down (R. Schmitt a. Möhlau, J. pr. 126, 202).

**Properties.**—Long red prisms (from alcohol). Melts under water, but insoluble therein and not volatile with steam. It begins to boil at 240°, but suffers decomposition at the same time. **Reactions.**—1. Reduced by alcoholic ammonium sulphide to the corresponding hydrazo-compound (q. v.). 2. Cold fuming HNO<sub>3</sub> forms a nitro-, and a di-nitro-, derivative.

**m-Oxy-benzene-m-azo-phenol Ethyl ether** [3:1]  $C_6H_4(OEt)_2-N_2-C_6H_4(OEt)$  [1:3]. **m-Azo-phenol** [91°]. Formed by reducing *m*-nitro-phenol in alcoholic solution with sodium amalgam (M. Buchstab, J. pr. [2] 29, 299).

**Properties.**—Orange prisms (from alcohol). Sol. ether. Insol. water and (difference from *o*-compound) in conc. HCl. Reduced by H<sub>2</sub>S and alcoholic ammonia to *m*-hydrazo-phenol.

**p-Oxy-benzene-p-azo-phenol**

[4:1]  $C_6H_4(OH).N_2-C_6H_4(OH)$  [1:4]. **p-Azo-phenol** [204°].

**Formation.**—1. By potash-fusion from *p*-nitroso-phenol (Jaeger, B. 8, 1439), *p*-nitro-phenol (Weselsky a. Benedikt, A. 196, 339), *p*-oxy-benzene-azo-benzene *p*-sulphonic acid, or *p*-sulpho-benzene-azo-benzene *p*-sulphonic acid (Bohn a. Hermann, B. 15, 5037).—2. From *p*-dialzo-phenol nitrate and phenol potassium.

**Properties.**—Slender brown needles with blue reflex (containing aq); sl. sol. water, v. sol. alcohol. Bromine gives a tetra-bromo derivative. Nitric acid (1, 2, 4)-di-nitro-phenol. Chlorine gives tri-chloro-phenol.

**Salt.**— $BaC_{12}H_9N_2O_4$ , 4aq.

**Ethyl ether**  $C_6H_4(OEt)_2-N_2-C_6H_4(OEt)$ . **p-Azo-phenol** [160°] (S. a. M.); [158°] (A.). Formed by adding sodium-amalgam (5 p.c.) to an alcoholic solution of *p*-nitro-phenyl-ethyl ether, precipitating the product with water, boiling it with dilute HCl to remove amido-phenyl-ethyl-ether, and crystallising from alcohol (Schmitt a. Möhlau, J. pr. 126, 199; Hepp, B. 10, 1652; Andrae, J. pr. 129, 333). **Properties.**—Glittering golden plates. M. sol. cold alcohol, v. sol. ether and chloroform. Distils with difficulty. **Reactions.**—1. Fuming HNO<sub>3</sub> forms the ethyl ether of di-nitro-phenol (q. v.) and two isomeric tri-nitro-azoxy-phenol ethyl ethers.—2. HClAq at 130° gives EtCl and *p*-azo-phenol  $N_2(C_6H_4OH)_2$ , but at 150° chloro-*p*-amido-phenol is got (Schmitt, J. pr. [2] 19, 313).

**p-Oxy-benzene-azo-diphenyl sulphonic acid**

[4:1]  $C_6H_4(OH).N_2-C_6H_4-C_6H_4.SO_3H$ . From diazotised *p*-amido-diphenyl sulphonic acid and phenol (Carnelley a. Schlevelmann, C. J. 49, 380). Yellow dye.— $BaA'_2$ ; insol. cold water.

**m-Di-oxy-benzene-azo-diphenyl sulphonic acid** [4:2:1]  $C_6H_4(OH)_2-N_2-C_6H_4-C_6H_4.SO_3H$ .

From diazotised *p*-amido-diphenyl sulphonic acid and resorcin (Carnelley a. Schlevelmann, C. J. 49, 382).— $NaA'$ .— $BaA'_2$ .

**p-Di-oxy-benzene-azo-diphenylsulphonic acid** [5:2:1]  $C_6H_4(OH)_2.N_2.C_6H_4.C_6H_4.SO_3H$ .

From diazotised *p*-amido-diphenyl sulphonic acid and hydroquinone (Carnelley a. Schlevelmann, C. J. 49, 382).

**p-Oxy-benzene-azo-phloroglucin**

$C_6H_4(OH).N_2-C_6H_4(OH)_3$ . Two modifications appear to be formed by the action of *p*-dialzo-phenol nitrate on phloroglucin (Weselsky a. Benedikt, J. 12, 227). (a) Red crystalline powder (containing 3aq), sol. alcohol. (b) Green amorphous mass, insol. alcohol.

**p-Oxy-benzene-azo-resorcin. Ethyl ether**

[4:1]  $C_6H_4(OEt)_2-N_2-C_6H_4(OH)_2$  [1:2:4]. [167°]. Formed by the action of *p*-dialzo-phenol on resorcin (Liebermann a. Kostanecki, B. 17, 883). Red plates. Sol. alkalis. Dissolves in H<sub>2</sub>SO<sub>4</sub> with a brownish-red colour.

**Di-oxy-benzene-azo-resorcin**

[2:6:1]  $C_6H_4(OH)_2-N_2-C_6H_4(OH)_2$  [1:2:4]. **Tetra-oxy-azo-benzene**.

**Di-ethyl ether**  $C_6H_4(OEt)_2.N_2.C_6H_4(OH)_2$ .

[182°]. Formed by combination of the di-ethyl ether of *o*-dialzo-resorcin  $C_6H_4(OEt)_2.N_2.OH$  [6:2:1] with resorcin. Light reddish-yellow needles. V. sol. alcohol and ether, insol. water. Dissolves in conc. alkali with a reddish yellow colour, which becomes a splendid carmine-red on dilution (Fukall, B. 20, 1151).

**Di-oxy-benzene-azo-resorcin**

[2:1:1]  $C_6H_4(OH)_2.N_2.C_6H_4(OH)_2$  [1:4:2]. **Tetra-oxy-azo-benzene**.

**Di-ethyl ether**

$C_6H_4(OEt)_2-N_2-C_6H_4(OH)_2$  [193°]. Formed by combination of the di-ethyl ether of *p*-dialzo-resorcin  $C_6H_4(OEt)_2.N_2.OH$  [4:2:1] with resorcin. Small brown needles or short prisms with green reflex. V. sol. alcohol, ether, and aqueous

alkalis, insol. water. Carmine-red dyestuff (Pukall, *B. 20*, 1144).

**Oxy-benzene-azo-resorcin-di-sulphonic acid**

*Mono-methyl ether*

$C_6H_4(OMe).N_2.C_6H_4(OH)(SO_3H)_2$ . Yellow plates (Stebbins, *A. C. J.* 5, 55).—BaA<sup>aq</sup>: needles.

*p*-Oxy-benzene-*p*-azo-toluene

[4:1]  $C_6H_4Me-N_2-C_6H_4(OH)$  [1:4]. [151°]. Formed by gently warming *p*-diazotoluene-*p*-toluide with phenol, *p*-toluidine being split off (Heumann a. Oeconomides, *B. 20*, 905), or by warming *p*-nitroso-toluene with *p*-toluidine acetate (Kimieli, *B. 8*, 1030). Orange prisms, with blue reflex.

*m*-Di-oxy-benzene-*o*-azo-toluene

[2:1]  $C_6H_4(CH_3)-N_2-C_6H_3(OH)_2$  [1:2:4]. [195°]. (W.); [178°] (F.). Formed by the action of *o*-diazotoluene on resorcin. Brownish-red felted needles.

*Acetyl derivative* [75°]. Orange-yellow plates (Wallach, *B. 15*, 2825; cf. Fischer, *B. 20*, 1579).

*m*-Di-oxy-benzene-*p*-azo-toluene

[4:1]  $C_6H_4(CH_3)-N_2-C_6H_4(OH)_2$  [1:2:4] [181°]. Prepared by the action of *p*-diazotoluene on resorcin, or by gently warming *p*-diazotoluene-*p*-toluide with resorcin, *p*-toluidine being split off (Heumann a. Oeconomides, *B. 20*, 906). Reddish-yellow needles: sol. alcohol, ether, and aqueous alkalis. *Acetyl derivative* [98°].

Oxy-benzene-azo-toluidine

[5:2:1]  $C_6H_4(CH_3)(NH_2)-N_2-C_6H_4OH$  [1:4]. [172°]. Formed by saponification of the acetyl derivative. Slender brown needles. Sol. alcohol and ether, v. sl. sol. cold water. Dissolves in aqueous acids and alkalis.

*Acetyl derivative*

$C_6H_4(CH_3)(NHAc)-N_2-C_6H_4OH$ . [253°]. Prepared by diazotising the mono-acetyl derivative of (1:2:4)-tolylene-diamine and combining it with phenol (Wallach, *B. 15*, 2826). Yellow plates. Sol. acetic acid and in aqueous alkalis, sl. sol. alcohol.

**Di-oxy-benzene-azo-xylene** (Wallach, *B. 15*, 25). Formed by adding diazo-xylene chloride to an alkaline solution of resorcin.

**Di-oxy-benzene-azo-xylene sulphonic acid**

[4:2:1]  $C_6H_4(OH)_2-N_2-C_6H_4Me.SO_3H$ . Prepared by the action of an alkaline solution of resorcin upon diazo-xylene sulphonic acid. Slender orange needles, sl. sol. hot water; m. sol. alcohol (Griess, *B. 11*, 2197).

**Oxy-carboxy-benzene-azo-naphthalene**

$C_{10}H_7-N_2-C_6H_4(OH)(CO_2H)$  [1:4:3]. From naphthylamine hydrochloride (9 g.), HCl, water (500 g.), and NaNO<sub>2</sub> (3.45 g.) at 0°, the filtrate being poured into a solution of salicylic acid (6.9 g.) and NaOH (6 g.) in water (500 g.). The liquid is filtered and the sodium salt ppd. by NaCl (P. F. Frankland, *C. J.* 37, 747). Salt.—NaA'. S. 07 (cold). Dyes silk pale yellow. Reduced by Sn and HCl to naphthylamino and amido-salicylic acid,  $C_{10}H_7(NH_2)(OH)CO_2H$ .

**Oxy-carboxy-benzene-azo-(β)-naphthol**

*Mono-methyl derivative*

$C_6H_4(OMe)(CO_2H)-N_2-C_{10}H_7(OH)$ . Prepared by the action of diazo-anisic acid on an alkaline solution of (β)-naphthol (Griess, *B. 14*, 2039). Small red needles or plates (containing 1½ aq.). Sl. sol. alcohol. A<sup>aq</sup>. BaA<sup>aq</sup>: red minute needles.

**Oxy-carboxy-benzene-azo-(β)-naphthol sulphonic acid.** *Methyl derivative*

$C_6H_4(OMe)(CO_2H)-N_2-C_{10}H_7(OH)(SO_3H)$ . From diazo-anisic acid and (β)-naphthol sulphonic acid. Brown needles. Dyes wool scarlet. BaA<sup>aq</sup>, 8 aq (Griess, *B. 14*, 2039).

**Oxy-carboxy-benzene-azo-(β)-naphthol-(α)-di-sulphonic acid** *Methyl derivative*

$C_6H_4(OMe)(CO_2H)-N_2-C_{10}H_6(OH)(SO_3H)_2$ . Prepared by the action of diazo-anisic acid on an alkaline solution of (β)-naphthol-(α)-di-sulphonic acid (Griess, *B. 14*, 2010). Small dark-red needles (containing 3 aq.). Sol. water, and alcohol, insol. ether. Dyes a bluish shade of scarlet. A<sup>aq</sup>. HK, 6 aq: red crystals, sol. hot water.

**Oxy-carboxy-benzene-azo-oxy-benzoic acid**

*Di-methyl derivative*

$C_6H_4(OMe)_2(CO_2H)-N_2-C_6H_4(OMe)_2(CO_2H)$ . Formed by the action of sodium-amalgam on an alkaline solution of nitro-anisic acid. Insol. water. BaA<sup>aq</sup> (Alexceff, *C. R.* 55, 172).

**Dioxy-carboxy-methyl-phthalide-azo-dioxy-phthalide-acetic acid**

*Tetra-methyl derivative*  $C_{12}H_{12}N_2O_{12}$  i.e.

*Azo-meconic-acetic acid*. [c. 257°]. Obtained by reduction of nitro-di-methoxy-phthalide-acetic acid  $C_6H(OMe)_2(NO)_2 \begin{array}{c} \diagup CO \\ \diagdown CH_2CH_2CO_2H \end{array}$  with zinc-dust and aqueous NH<sub>3</sub>. Yellow crystals. Insol. water. Dissolves in conc. H<sub>2</sub>SO<sub>4</sub> with a deep blueish-violet colour (Kleeman, *B. 20*, 880).

**Tri-oxy-carboxy-toluene-azo-tri-oxy-toluic acid.** *Anhydride of the tetra-methyl derivative.*

[c. 245]. Formed by reduction of nitroso-opianic acid  $C_6H(OMe)_2(NO)(CH(O)(CO_2H))$  with zinc-dust and aqueous NH<sub>3</sub>. Dissolves in alkalis with a yellow colour, in conc. H<sub>2</sub>SO<sub>4</sub> with an intense purple colour. — AgA': microscopic needles (from hot water). — EtA': [101°], yellow needles, v. sl. alcohol, ether, and benzene (Kleemann, *D. 20*, 878).

**(β)-Oxy-naphthalene-azo-hippuric acid**

$CO_2H.CH_2.NH.CO.C_6H_4-N_2-C_{10}H_6(OH)$ . Prepared by the action of diazo-hippuric acid on an alkaline solution of (β)-naphthol (Griess, *B. 14*, 2010). Reddish-yellow needles. Sl. sol. alcohol, v. sl. sol. water and ether.

**(α)-Oxy-(α)-naphthalene-(α)-azo-naphthalene-(α)-sulphonic acid**

[4:1]  $C_{10}H_6(OH)-N_2-C_{10}H_6SO_3H$  [1:4]. From diazotised (α)-naphthylamine sulphonic acid and (α)-naphthol. The absorption-spectrum has been examined by Hartley (*C. J.* 51, 198).

**(β)-Oxy-naphthalene-azo-naphthalene sulphonic acid**  $C_{10}H_7(OH)-N_2-C_{10}H_6SO_3H$ . From diazotised (α)-naphthylamine sulphonic acid and (β)-naphthol (Caro; Griess, *B. 11*, 2199). Reddish-brown needles (from alcohol). Red dye.—BaA<sup>aq</sup>. The absorption-spectrum has been examined by Hartley (*C. J.* 51, 197).

**Oxy-propyl-carboxy-benzene-azo-oxy-propyl-benzoic acid**

$CO_2H.C_3H_7(C(OH)Me_2)-N_2-C_6H_4(C(OH)Me_2)CO_2H$ . Formed by reduction of nitro-oxy-propyl-benzoic acid with sodium-amalgam and water (Widmann, *B. 15*, 2550). Yellow plates. V. sl. sol.

most ordinary solvents, sl. sol. acetic acid.— $\text{Na}_2\text{A}''$  10aq: thin red rectangular tables.

**Oxy-sulpho-benzene-azo-benzoic acid**

[3:1]  $\text{C}_6\text{H}_4(\text{CO}_2\text{H})-\text{N}_2-\text{C}_6\text{H}_4(\text{OH})(\text{HSO}_3\text{H})$  [1:4:3]. Prepared by the action of *m*-diazobenzoic acid on an alkaline solution of phenol-*o*-sulphonic acid (Griess, *B.* 14, 2033). Brownish-red crystals (containing  $\frac{1}{2}$ aq). Sol. water, alcohol and ether. Yellow dye. Salts.— $\text{A}''\text{HKaq}$ : yellow plates or needles, sl. sol. cold water.— $\text{A}''_2\text{H}_2\text{Ba}$ : small yellow needles or plates.— $\text{A}''\text{Ba aq}$ : yellow crystalline pp.

**Oxy-sulpho-benzene-azo-naphthalene sulphonic acid**  $\text{C}_{10}\text{H}_7(\text{OH})(\text{SO}_3\text{H})-\text{N}_2-\text{C}_{10}\text{H}_6\text{SO}_3\text{H}$ . From diazotising (a)-naphthylamine sulphonic acid and phenol sulphonic acid (Stebbins, *A. C. J.* 2, 446).

**Oxy-toluene-azo-toluene sulphonic acid**

[4:2:1]  $\text{C}_6\text{H}_4(\text{CH}_3)(\text{SO}_3\text{H})-\text{N}_2-\text{C}_6\text{H}_4(\text{CH}_3)(\text{OH})$  [1:5:2]. Formed by the action of *p*-diazotoluene sulphonic acid (by diazotising *p*-toluidine-sulphonic acid) on an alkaline solution of *p*-cresol (Nölting a. Kohn, *B.* 17, 358). Reddish-brown crystals with violet reflection. V. sol. water, sl. sol. alcohol. Salts.— $\text{A}''\text{Na}$ : soluble yellow plates.— $\text{A}''_2\text{Ba aq}$ : small reddish-brown needles, sl. sol. hot water.

**Diphenyl-azo-diphenyl**

$\text{C}_6\text{H}_5\text{C}_6\text{H}_5-\text{N}_2-\text{C}_6\text{H}_5\text{C}_6\text{H}_5$  [250°]. Orange-red plates. Sol. ether, insol. water, alcohol, and acetic acid. Formed by reduction of *p*-nitro-diphenyl with sodium-amalgam, and by the dry distillation of hydrazo-diphenyl. Prepared by oxidising an alcoholic solution of hydrazo-diphenyl with  $\text{FeCl}_3$  (Zimmermann, *B.* 13, 1962).

**Phenyl-acetic-azo-phenyl-acetic acid v. exo-CARBOXY-TOLUENE-AZO-PHENYL-ACETIC ACID.**

**Phenyl-amido-benzene-azo-benzene-sulphonic acid**

[4:1]  $\text{C}_6\text{H}_4(\text{SO}_3\text{H})-\text{N}_2-\text{C}_6\text{H}_4\text{NPh}$  [1:4]. *Tropaeoline O.O.* Prepared by the action of *p*-diazobenzene sulphonic acid on an alcoholic solution of diphenylamine (Witt, *C. J.* 35, 187; *B.* 13, 262). Steel-blue hair-like needles. Sl. sol. water. Salts.— $\text{A}''\text{K}$ : flat yellow needles; sl. sol. cold water.— $\text{A}''\text{Na}$ .— $\text{A}''\text{NH}_4$ .— $\text{A}''\text{NHMe}$ : large yellow leaflets.— $\text{A}''_2\text{Ba}$  and  $\text{A}''_2\text{Ca}$ : insoluble yellow pps.

**Phenyl-glycollic-azo-phenyl glycollic acid**  $\text{N}_2(\text{C}_6\text{H}_4\text{OCH}_2\text{CO}_2\text{H})_2$  [162°].

**Preparation.**—*o*-Nitrophenylglycollic acid (18.6 g.) water (140 g.) and  $\text{Na}_2\text{CO}_3$  (5 g.) are treated at 60° with sodium-amalgam (215 g. of 4 p.c. amalgam). The crystals which separate on cooling are dissolved in very little water and the acid is pptd. by acetic acid. The product is recrystallised several times from alcohol (A. Thate, *J. pr.* [2] 29, 161).

**Properties.**—Orange silky needles, containing 2aq (from water or dilute alcohol). When dry (at 110°) it is brick-red. Sol. ether, alkalis and strong acids. Its solutions are yellow or red.

**Reactions.**—1. Aqueous solution is acid to litmus and gives with  $\text{AgNO}_3$  a red gelatinous pp., and with  $\text{Pb}(\text{OAc})_2$  a flocculent yellow pp.—2. Reduced by alcoholic  $\text{NH}_4$  and  $\text{H}_2\text{S}$  to the corresponding hydrazo-compound, the potassium salt of which,  $\text{N}_2\text{H}_2(\text{C}_6\text{H}_4\text{OCH}_2\text{CO}_2\text{K})_2$  3aq, crystallises from alcohol in rhombohedra.

**Salts.**— $\text{K}_2\text{A}''$  3aq. Orange plates. Its solution gives with  $\text{BaCl}_2$  a red crystalline pp.; with  $\text{Pb}(\text{OAc})_2$  an orange flocculent pp.; with

$\text{AgNO}_3$ , a red flocculent pp.; with  $\text{FeCl}_3$ , an orange pp.; with  $\text{CuSO}_4$ , a brownish-yellow pp.; with  $\text{HgCl}_2$ , on boiling, a red pp.; with  $\text{MgSO}_4$ , after some time, an orange crystalline pp.— $\text{Na}_2\text{A}''$  3aq.— $\text{Ag}_2\text{A}''$  3aq.— $\text{BaA}''$  2aq.— $\text{CaA}''$  8aq.

**Ethyl ether.** Et<sub>2</sub>A''. [111°]. Red crystals.

**Phenyl-glyoxylic-azo-phenyl-glyoxylic acid**  $\text{CO}_2\text{H.CO}_2\text{C}_6\text{H}_4-\text{N}_2-\text{C}_6\text{H}_4\text{CO.CO}_2\text{H}$ . *Azo-benzoyl-formic acid*. Orange needles (containing 2aq and melting at [135°]. When dry it melts at about 151°. Prepared by reduction of *m*-nitro-benzoyl-formic acid with  $\text{FeSO}_4$  and  $\text{KOH}$ ; yield, 50 p.c. (Thompson, *B.* 16, 1308). Sl. sol. ether and cold water, insol. acidulated water, chloroform, or benzene. Very stable body. A cold saturated aqueous solution of the acid gives with  $\text{BaCl}_2$  or  $\text{CaCl}_2$  a micro-crystalline pp., with  $\text{AgNO}_3$  a yellow flocculent precipitate.— $\text{A}''\text{Ba}$ : orange crystalline pp., insol. water.— $\text{A}''\text{Ag}_2$ : orange-yellow slightly soluble pp.

**Phenyl-pyrrol-azo-benzene**

$\text{C}_6\text{H}_5\text{N}_2\text{C}=\text{CH}$   
 $\text{C}_6\text{H}_5\text{N}_2\text{C}_6\text{H}_4\text{NPh}$  probably  $\text{NPh} \mid$   
 $\text{HC}=\text{CH}$

[117°]. Prepared by adding diazobenzene chloride (1 mol.) to phenyl-pyrrol (1 mol.) dissolved in alcohol containing  $\text{AcONa}$ . Brown prisms or long reddish-yellow needles with blueish reflection. V. sol. alcohol. Dissolves in conc.  $\text{H}_2\text{SO}_4$  with a reddish-violet colour, in alcoholic  $\text{HCl}$  with a blood-red colour. Reduced by zinc-dust and  $\text{NH}_4$  or  $\text{NaOH}$  to aniline and (probably) amido-phenyl-pyrrol (O. Fischer a. Hepp, *B.* 19, 2256).

**Di-propyl-amido-benzene-azo-di-propyl-aniline**  $\text{C}_6\text{H}_4\text{N}(\text{C}_3\text{H}_7)_2-\text{N}_2-\text{C}_6\text{H}_4\text{N}(\text{C}_3\text{H}_7)_2$ . *Di-propyl-aniline-azylane*. [96°]. Formed by passing  $\text{NO}$  through an alcoholic solution of di-propyl-aniline (Lippmann a. Fleissner, *B.* 15, 2140; 16, 1417). Large trimetric crystals,  $a:b:c = 1:629:913$ . Pictate  $\text{B}''(\text{C}_6\text{H}_4\text{NO}_2)_2\text{OH}_2$ : orange-red insoluble crystals.—Periodide  $\text{B}''_2\text{I}_2$ : violet glistening needles.

**Pyrrol-azo-benzene**  $\text{C}_6\text{H}_5-\text{N}_2-\text{C}_6\text{H}_4\text{NH}$   
 $\text{C}_6\text{H}_5\text{N}_2\text{C}=\text{CH}$   
 probably  $\text{NH} \mid$ . [62°]. Prepared by  $\text{HC}=\text{CH}$

adding the calculated quantity of a moderately conc. solution of diazo-benzene chloride to a well-cooled solution of pyrrol (2 pts.) in alcohol (100 pts.) with addition of sodium acetate (5 pts.) (Fischer a. Hepp, *B.* 19, 2251). Yellow needles. V. sol. alcohol, ether, and petroleum spirit, sl. sol. water. It has basic properties. Easily reduced (e.g., by zinc-dust and alkalis) to aniline and (probably) amido-pyrrol. Readily combines in alkaline or neutral solution with a further quantity of diazo-compound, giving disazo-bodies. Dissolves easily in dilute  $\text{HCl}$  with a reddish-yellow colour. Dissolves in conc.  $\text{H}_2\text{SO}_4$  with a yellow colour. The platino-chloride forms small red sparingly soluble needles.

**Pyrrol-*p*-azo-di-methyl-aniline**

$\text{C}_6\text{H}_4(\text{NMe})_2-\text{N}_2-\text{C}_6\text{H}_4\text{NH}$ . [159°]. Formed by combining *p*-diazodi-methyl-amido-benzene with pyrrol in dilute alkaline solution. Glittering green plates. Dissolves in very dilute  $\text{HCl}$  with a grass-green colour, in conc.  $\text{HCl}$  with a greenish-yellow colour.  $\text{PtCl}_4$  gives a dark green amorphous pp. (Fischer a. Hepp, *B.* 19, 2257).

**Pyrrol-( $\alpha$ )-azo-naphthalene**  $C_{10}H_7.N_2.C_6H_4NH$   
 $C_6H_4.N_2.Q = CH$   
probably  $\begin{array}{c} NH \\ | \\ HC = CH \end{array}$  [103°]. Formed by

adding ( $\alpha$ )-diao-naphthalene chloride (1 mol.) to pyrrol (1 mol.) dissolved in alcohol containing sodium acetate. Reddish-yellow plates. V. sol. alcohol (O. Fischer a. Hepp, B. 19, 2255).

**Pyrrol-( $\beta$ )-azo-naphthalene**

$C_{10}H_7-N_2-C_6H_4NH$  probably  $\begin{array}{c} NH \\ | \\ HC = CH \end{array}$  [101°]. Prepared by adding ( $\beta$ )-diao-naphthalene chloride to an alcoholic solution of pyrrol containing sodium acetate. Gold-bronzy plates (O. Fischer a. Hepp, B. 19, 2255).

**Pyrrol- $p$ -azo-toluene**  $C_6H_4.Me-N_2-C_6H_4NH$   
 $C_6H_4.N_2.Q = CH$   
probably  $\begin{array}{c} NH \\ | \\ HC = CH \end{array}$  [82°]. Prepared by

adding  $p$ -diao-toluene chloride (1 mol.) to pyrrol (1 mol.) dissolved in alcohol containing sodium acetate (Fischer a. Hepp, B. 19, 2254).

**$m$ -Sulphi-benzene-azo-benzene- $m$ -sulphinic acid**  $C_6H_4(SO_2H)-N_2-C_6H_4(SO_2H)$ . *Azo-benzene di-sulphinic acid*. Obtained from  $C_6H_4(SO_2SH).N_2.C_6H_4(SO_2SH)$  by treatment with sodium amalgam (Limpricht, B. 18, 1473; Bauer, A. 229, 363). Yellowish amorphous mass, sl. sol. cold water, insol. ether.

**Salts.**— $NaA''$  2aq. —  $CaA''$  1½aq. —  $BaA''$  —  $PbA''$ . These salts are readily oxidised (e.g. by  $KMnO_4$  or  $I$  in  $KI$ ) to the corresponding di-sulphonates. Conc. ammoniac sulphide converts them into the di-thio-di-sulphonates. They are not reduced by sodium amalgam. Boiled with  $HCl$  the acid clots together, but conc.  $HCl$  at 110° forms (2 p.c. of) an isomeric base.

**$p$ -Sulphi-benzene-azo-benzene- $p$ -sulphinic acid**  $SO_2H.C_6H_4-N_2-C_6H_4.SO_2H$ .

*Azo-benzene  $p$ -di-sulphinic acid*. Prepared from  $SO_2Cl.C_6H_4-N_2-C_6H_4.SO_2Cl$  and  $Ba(SH)_2$ , or from  $NaS.SO_2.C_6H_4.N_2.C_6H_4.SO_2Na$  by sodium amalgam (Limpricht, B. 18, 1475; Bauer, A. 229, 363). The free acid is ppd. by  $HCl$  from its salts as a bulky yellow mass, sparingly soluble in water or alcohol. Clots together when heated with acids. **Salts.**— $NaA''$  4aq. —  $BaA''$ .

**Sulpho-benzene-azo-amido-ethane v. SULPHO-BENZENE-AZO-ETHYLAMINE.**

**$p$ -Sulpho-benzene-azo-di-amido-benzoic acid** [4:1]  $C_6H_4(SO_3H)-N_2-C_6H_4(NH_2).CO_2H$  [1:4:2:6]. Formed by the action of  $p$ -diao-benzene-sulphonic acid on  $s$ -di-amido-benzoic acid (Griess, B. 15, 2199). Needles or plates. Sl. sol. water, cold alcohol, and ether. Very unstable. Decomposes by boiling with water. On reduction it gives sulphanilic acid and (5:3:2:1)-tri-amido-benzoic acid.

**Sulpho-benzene-azo-aniline-sulphonic acid** [4:1]  $C_6H_4(HSO_3)-N_2-C_6H_4(HSO_3)NH_2$  [1:7:4]. *Amido-azo-benzene disulphonic acid*. Formed by sulphonation of  $p$ -amido-benzene-azo-benzene- $p$ -sulphonic acid (Griess, B. 15, 2187). Violet glistening needles. Sol. hot water. Dyes silk and wool yellow. On reduction with tin and  $HCl$  it gives sulphanilic acid and  $p$ -phenylenediamino-sulphonic acid.  $BaA''$  7½aq: orange needles, sol. hot water.

**$m$ -Sulpho-benzene-azo-benzene- $m$ -sulphonic acid** [3:1]  $SO_3H.C_6H_4-N_2-C_6H_4.SO_3H$  [1:3].

**Formation.**—1. From nitro-benzene  $m$ -sulphonic acid by treatment with sodium-amalgam (Claus a. Moser, B. 11, 762) or, better, with powdered zinc and  $KOH$  (Mahrenholtz a. Gilbert, A. 202, 332).—2. One of the acids got by sulphonating benzene-azo-benzene at 150° (Janovsky, M. 3, 244).—3. From potassium  $m$ -amido-benzene sulphonate and  $KMnO_4$ .

Monoclinic prisms, sl. sol. water and alcohol, insol. ether.

**Salts.**— $NaA''$  3½aq: monoclinic crystals. —  $(NH_4)_2A''$  2aq. —  $CaA''$  4aq. —  $BaA''$  5aq. —  $PbA''$  4½aq.

**Amide** [290°]. Prisms, sl. sol. water.

**Ethyl ether EtA''** [100°].

**Chloride**  $C_6H_4(SO_2Cl).N_2.C_6H_4(SO_2Cl)$  [166°]. Acts upon cold conc. aqueous  $Ba(SH)_2$ , thus:  $C_6H_4(SO_2Cl).N_2.C_6H_4(SO_2Cl) + 2BaH_2S_2 = N_2(C_6H_4(SO_2S)_2)Ba + BaCl_2 + 2H_2S$  forming thio-sulpho-benzene-azo-benzene-thio-sulphonic acid, part of which then decomposes according to the following equation:  $N_2(C_6H_4(SO_2S)_2)Ba + H_2S = H.N_2(C_6H_4(SO_2S)_2)Ba + S$  forming the barium salt of hydrazobenzene di-thio-di-sulphonic acid (Bauer, A. 229, 353).

**$m$ -Sulpho-benzene-azo-benzene- $p$ -sulphonic acid** [4:1]  $C_6H_4(HSO_3)-N_2-C_6H_4(HSO_3)$  [1:3]. Formed, together with the  $p$ - $p$ -acid, by heating benzene-azo-benzene with  $H_2SO_4$  at 160° (Limpricht, B. 14, 1356; Rodatz, A. 215, 216), and by the oxidation of a mixture of  $m$ - and  $p$ -potassium amido-benzene sulphonate with  $KMnO_4$ . Uncrystallised syrup. On heating with dilute  $HCl$  to 150° it gives  $p$ - and  $m$ -amido-benzene-sulphonic acids (Limpricht, B. 15, 1155).

**Salts.**— $K_2A''$  2½aq: yellow needles, v. sol. water. —  $Ag_2A''$ .

**Chloride** [125°]: red needles.

**Amide** [258°]: slender yellow needles.

**$p$ -sulpho-benzene-azo-benzene- $p$ -sulphonic acid** [4:1]  $SO_3H.C_6H_4-N_2-C_6H_4.SO_3H$  [1:4].

**Formation.**—1. By oxidising amido-benzene- $p$ -sulphonic acid with  $KMnO_4$  (Laar, B. 14, 1928; Limpricht, B. 18, 1414).—2. Among the products of the sulphonation of benzene-azo-benzene at 160° (Limpricht, B. 14, 1856; 15, 1155; Janovsky, M. 3, 242).

**Properties.**—Ruby-red needles containing 2 or 3 aq (J.), or aq (L.). Melts at about 60° or, when dry, at about 150°.  $HClAq$  at 150° gives sulphanilic acid and other products.

**Salts:**  $K_2A''$  2½aq: sl. sol. water. —  $Na_2A''$  —  $(NH_4)_2A''$  —  $Ag_2A''$  —  $CaA''$  —  $PbA''$  aq. —  $CuA''$  6aq.

**Chloride** [222°]. Red needles.

**Amide** [above 300°]: orange plates or needles, sl. sol. hot water.

**Di-sulpho-benzene-azo-benzene-disulphonic acid** [5:3:1]  $C_6H_4(SO_3H)_2.N_2.C_6H_4(SO_3H)_2$  [1:3:5]. From nitro-benzene-di-sulphonic acid, zinc dust, and baryta (Reiche, A. 203, 64). Very deliquescent crystals. —  $K_2A''$  3aq. —  $BaA''$  5aq.

**Di-sulpho-benzene-azo-benzene-di-sulphonic acid** [4:3:1]  $C_6H_4(SO_3H)_2.N_2.C_6H_4(SO_3H)_2$  [1:3:4]. From the corresponding nitro-benzene-di-sulphonic acid, zinc dust, and baryta-water (Reiche, A. 203, 70). **Salts.**— $K_2A''$  3aq. —  $BaA''$  4aq.

**Chloride** [58°]: radiating needles.

**Amide** [222°]: white needles.

**$p$ -Sulpho-benzene-azo- $o$ -cresol.**

[4:1]  $C_6H_4(SO_3H)-N_2-C_6H_3(CH_3)(OH)$  [1:3:4].

Formed by the action of diazo-benzene-*p*-sulphonic acid (by diazotising sulphanilic acid) on an alkaline solution of *o*-cresol (Nölting a. Kohn, *B.* 17, 864). Small reddish-brown needles. Sol. hot water. V. sl. sol. alcohol. On reduction with tin and HCl it gives sulphanilic acid and amido-*o*-cresol  $C_6H_3(CH_3)(NH_2)(OH)$  [1:5:2].

Salts:—A'Na 2aq: yellow soluble plates. A'Ba 3aq: yellow tables, sl. sol. hot water.

*p*-Sulpho-benzene-azo-*m*-cresol

[4:1]  $C_6H_4(SO_3H)-N_2-C_6H_3(CH_3)(OH)$  [1:2:4]. Formed by the action of diazobenzene-*p*-sulphonic acid on an alkaline solution of *m*-cresol (Nölting a. Kohn, *B.* 17, 366). Small reddish-brown crystals with violet reflex. V. sol. water and hot alcohol. Orange-yellow dye stuff. On reduction it gives sulphanilic acid and amido-*m*-cresol  $C_6H_3(CH_3)(NH_2)(OH)$  [1:2:5].

Salts: A'Na: small yellow soluble needles.

A'Ba: yellow plates, v. sl. sol. cold water.

Sulpho-benzene-azo-*p*-cresol

[4:1]  $C_6H_4(SO_3H)-N_2-C_6H_3(CH_3)(OH)$  [1:5:2].

or

Formation.—1. By the action of *p*-diazobenzene-sulphonic acid on an alkaline solution of *p*-cresol.—2. By sulphonation of benzene-azo-*p*-cresol (Nölting a. Kohn, *B.* 17, 355). Yellowish-brown plates with violet reflex. V. sol. water and hot alcohol. Dyes silk and wool orange-yellow. On reduction with tin and HCl it yields sulphanilic acid and amido-*p*-cresol  $C_6H_3(CH_3)(NH_2)(OH)$  [1:3:4].

Salts: A'Na: soluble yellow plates. A'K 3aq.—A'Mg 5aq.—A'Ba: yellowish-brown tables, sl. sol. hot water.

*p*-Sulpho-benzene-azo- $\psi$ -cumenol

[4:1]  $C_6H_4(HSO_3)-N_2-C_6H_3(CH_3)_2OH$  [1:3:5:6:2]. Formed by combining diazo-benzene-*p*-sulphonic acid with  $\psi$ -cumenol [70].—KA' 2aq: orange needles (Liebermann a. Kostanecki, *B.* 17, 887).

Sulpho-benzene-azo-ethylamine. Potassium salt.  $C_6H_4(SO_3K)-N_2-CH(NH_2)CH_3$ . From the potassium salt of the corresponding nitro-compound by reducing with ammonium sulphide (Kappeler, *B.* 12, 2285). Silvery plates (from water); sl. sol. water, insol.  $Na_2CO_3$  aq. NaOH aq dissolves it with crimson colour.

*m*-Sulpho-benzene-azo-( $\beta$ )-naphthol

[3:1]  $C_6H_4(HSO_3)-N_2-C_{10}H_7OH$  [1:4]. Prepared by the action of an alkaline solution of ( $\alpha$ )-naphthol on *m*-diazobenzene sulphonic acid (Griess, *B.* 11, 2197). Small greenish leaflets. Sl. sol. cold water and cold alcohol.

*m*-Sulpho-benzene-azo-( $\beta$ )-naphthol

[3:1]  $C_6H_4(HSO_3)-N_2-C_{10}H_7(OH)$  [1:2] or

$C_6H_4(HSO_3)-HN_2 \begin{array}{c} \text{O} \\ \parallel \\ \diagup \\ C_{10}H_7 \end{array}$ . Prepared by the action of an alkaline solution of ( $\beta$ )-naphthol on *m*-diazobenzene sulphonic acid (Griess, *B.* 11, 2197). Slender red needles. V. sol. alcohol and water. BaA' 5aq: yellowish-red scales. Sl. sol. water.

*p*-Sulpho-benzene-azo-( $\alpha$ )-naphthol

[4:1]  $C_6H_4(SO_3H)-N_2-C_{10}H_7(OH)$  [1:4]. Tropaeoline OOO, No. 1. From *p*-diazobenzene sulphonic acid and an alkaline solution of ( $\alpha$ )-naphthol (Liebermann a. Jacobsen, *A.* 211, 61). Orange-

dye. Its absorption spectrum is given by Hartley (*C. J.* 51, 184).

*p*-Sulpho-benzene-azo-( $\beta$ )-naphthol

[4:1]  $C_6H_4(SO_3H)-N_2-C_{10}H_7(OH)$  [1:2] or  $C_6H_4(SO_3H)-HN_2 \begin{array}{c} \text{O} \\ \parallel \\ \diagup \\ C_{10}H_7 \end{array}$  Tropaeoline OOO No. 2

From *p*-diazobenzene sulphonic acid and ( $\beta$ )-naphthol (W. v. Miller, *B.* 13, 268; Hofmann, *B.* 10, 1378; Griess, *B.* 11, 2198). The absorption spectrum has been examined by Hartley (*C. J.* 51, 185).

*p*-Sulpho-benzene-azo-( $\beta$ )-naphthol sulphonic acid [4:1]  $C_6H_4(HSO_3)-N_2-C_{10}H_7(HSO_3)OH$ . Prepared by the action of *p*-diazobenzene sulphonic acid on an alkaline solution of ( $\beta$ )-naphthol sulphonic acid (Griess, *B.* 11, 2198; Stebbins, *A. C. J.* 2, 236). Yellowish red crystals. Excessively soluble in water. BaA' 7½aq: difficultly soluble orange microscopic needles.

*p*-Sulpho-benzene-azo-( $\alpha$ )-naphthylamine

[4:1]  $C_6H_4(HSO_3)-N_2-C_{10}H_7NH_2$  [1:4]. From diazotised sulphanilic acid and ( $\alpha$ )-naphthylamine (Griess, *B.* 12, 427). Brownish-violet needles, v. sl. sol. boiling water. Its acid solutions have a deep magenta colour (Griess's test for nitrous acid); its alkaline solutions are orange. On reduction with tin and HCl it gives sulphanilic acid and (1,4)-naphthylene-diamine.

Salts: KA' 3aq: brownish-yellow plates, sol. hot water.—BaA' 3aq: sparingly soluble brown needles (Griess, *B.* 15, 2190).

*p*-Sulpho-benzene-azo-( $\beta$ )-naphthylamine

[4:1]  $C_6H_4(HSO_3)-N_2-C_{10}H_7NH_2$  [1:2] or  $C_6H_4(HSO_3)-HN_2 \begin{array}{c} \text{HN} \\ \diagup \\ C_{10}H_7 \end{array}$ . Formed by the

action of *p*-diazobenzene-sulphonic acid on ( $\beta$ )-naphthylamine hydrochloride (Griess, *B.* 15, 2191). Small yellowish-red needles. Sl. sol. water, v. sol. hot alcohol, insol. ether. On reduction with tin and HCl it gives sulphanilic acid and (1,2)-naphthylene-diamine.—KA' 7½aq: orange plates, sol. hot water.

Sulpho-benzene-azo-( $\alpha$ )-naphthylamine sulphonic acid  $C_6H_4(SO_3H)N_2C_{10}H_7(SO_3H)NH_2$  [1:4:2]. Formed by the action of *p*-diazobenzene-sulphonic acid on ( $\alpha$ )-naphthylamine-sulphonic acid (Griess, *B.* 15, 2194). Needles or plates. Sol. water and alcohol, insol. ether, dyes silk and wool orange.—BaA' 7½aq: red needles or plates, sol. hot water.—BaH<sub>2</sub>A' 8aq: sparingly soluble violet-brown needles.

*p*-Sulpho-benzene-azo-( $\beta$ )-naphthyl-phenylamine  $C_6H_4(SO_3H)-N_2-C_{10}H_7.NHC_6H_5$  or  $C_6H_4(SO_3H).HN_2.C_{10}H_7 \begin{array}{c} \diagup \\ N.C_6H_5 \end{array}$ . Prepared by slowly

adding dry *p*-diazobenzene-sulphonic acid (18 g.) to a solution of phenyl-( $\beta$ )-naphthylamine (22 g.) in glacial acetic acid (100 c.c.) at c. 50°, followed by finely powdered dry  $K_2CO_3$  (7 g.); the compound separates out in glistening red needles of the potassium-salt. It is a splendid scarlet dyestuff, but is very fugitive in light. The potassium salt is easily soluble in water; when cold its solution solidifies to a transparent red jelly. HCl precipitates the free acid. By SnCl<sub>2</sub> it is reduced to phenyl-*o*-naphthylene-diamine and sulphanilic acid. By boiling with dilute

mineral acids it is converted into naphthophenazine and sulphanilic acid:

$\text{C}_6\text{H}_5\text{N} \begin{smallmatrix} \diagup \\ \diagdown \end{smallmatrix} \text{C}_6\text{H}_4 + \text{C}_6\text{H}_4(\text{NH}_2)\text{SO}_3\text{H}$ . The Ba and Ca salts are crystalline insoluble pps. (Witt, B. 20, 572).

*p*-Sulpho-benzene-azo-nitro-isobutane  $\text{C}_6\text{H}_4(\text{HSO}_3)_2\text{N}_2\text{C}_4\text{H}_8(\text{NO}_2)$ . Prepared by the action of *p*-diazobenzene-sulphonic acid on an alkaline solution of nitro-iso-butane. —KA' aq: orange-yellow needles. Soluble in alkalis to a red solution. Dyes silk orange (Kappeler, B. 12, 2288).

*p*-Sulpho-benzene-azo-nitro-ethane  $\text{C}_6\text{H}_4(\text{HSO}_3)_2\text{N}_2\text{C}_2\text{H}_5(\text{NO}_2)$ . Prepared by the action of *p*-diazobenzene-sulphonic acid on an alkaline solution of nitro-ethane. A'K: golden yellow leaflets, sparingly soluble in cold water, soluble in alkalis to a blood-red solution (Kappeler, B. 12, 2286).

*p*-Sulpho-benzene-azo-nitro-methane  $\text{C}_6\text{H}_4(\text{HSO}_3)_2\text{N}_2\text{CH}_3(\text{NO}_2)$ . Prepared by the action of *p*-diazobenzene-sulphonic acid on an alkaline solution of nitro-methane. —KA' 3aq: orange needles. Dyes silk orange (Kappeler, B. 12, 2286).

*p*-Sulpho-benzene-azo-nitro-propane  $\text{C}_6\text{H}_4(\text{HSO}_3)_2\text{N}_2\text{C}_3\text{H}_7(\text{NO}_2)$ . Prepared by the action of *p*-diazobenzene-sulphonic acid on an alkaline solution of nitro-isopropane. A'K: light-yellow leaflets. Has no dyeing power. Insoluble in alkalis (Kappeler, B. 12, 2287).

*p*-Sulphobenzene-azo-orein  $[4:1] \text{C}_6\text{H}_4(\text{HSO}_3)_2\text{N}_2\text{C}_6\text{H}_4(\text{CH}_3)(\text{OH})_2$ . Small yellowish-red needles. Difficultly soluble in water. Prepared by the action of an alkaline solution of orein upon *p*-diazobenzene-sulphonic acid. —KA' 2aq (Griess, B. 11, 2196).

*p*-Sulpho-benzene-azo-o-oxy-benzoic acid  $[4:1] \text{C}_6\text{H}_4(\text{SO}_3\text{H})\text{N}_2\text{C}_6\text{H}_3(\text{OH})(\text{CO}_2\text{H})$  [1:4:5]. From diazotised sulphanilic acid and an alkaline solution of salicylic acid. Golden needles; sl. sol. hot water (Griess, B. 11, 2196; Stebbins, B. 13, 716). BaH<sub>2</sub>A''.

*p*-Sulpho-benzene-azo-oxy-quinoline  $\text{C}_6\text{H}_4(\text{HSO}_3)_2\text{N}_2\text{C}_8\text{H}_6(\text{OH}) \begin{smallmatrix} \text{CH:CH} \\ | \\ \text{N:CH} \end{smallmatrix}$ . Formed

by the combination of *p*-diazobenzene-sulphonic acid with (B. 4)-oxy-quinoline (Fischer a. Renouf, B. 17, 1642). Small needles. Orange dye.

*p*-Sulpho-benzene-azo-phenol disulphonic acid  $\text{C}_6\text{H}_4(\text{SO}_3\text{H})\text{N}_2\text{C}_6\text{H}_3(\text{SO}_3\text{H})(\text{OH})$ . Formed by heating azoxybenzene with fuming H<sub>2</sub>SO<sub>4</sub>. Small soluble flat red needles with green lustre. On reduction it gives *p*-amido-benzene-sulphonic acid and amido-phenol-di-sulphonic acid.

Salts. —A''K<sub>2</sub> 3aq: yellow microscopic needles, easily soluble. Bromine-water gives tri-bromo-phenol. —A''Ag: unstable red pp. —A''Ba<sub>2</sub> 7aq: brown crystalline pp. —A''Pb<sub>2</sub> 1½aq.

Chloride: red crystalline powder [220°]. Amide: yellow plates [260°], sparingly soluble in alcohol (Limpriecht, E. 15, 1297; Wilsing, A. 215, 234).

*p*-Sulpho-benzene-azo-xyleneol  $[4:1] \text{C}_6\text{H}_4(\text{SO}_3\text{H})\text{N}_2\text{C}_6\text{H}_4\text{Me}_2\text{OH}$  [1:3:5:2]. Formed by combining diazobenzene-*p*-sulphonic acid with *m*-xyleneol C<sub>6</sub>H<sub>3</sub>Me<sub>2</sub>(OH) [1:3:4]

(Grevink, B. 19, 148). Dyes wool and silk a brownish yellow from an acid bath. On reduction it yields sulphanilic acid and *o*-amido-*m*-xyleneol C<sub>6</sub>H<sub>3</sub>Me<sub>2</sub>(NH<sub>2</sub>)(OH) [5:3:1:2].

Sulpho-carboxy-benzene-azo-(β)-naphthol-(a)-di-sulphonic acid

$\text{C}_6\text{H}_4(\text{CO}_2\text{H})(\text{SO}_3\text{H})\text{N}_2\text{C}_{10}\text{H}_7(\text{OH})(\text{SO}_3\text{H})_2$ . Prepared by the action of *m*-diazosulphobenzoic acid on an alkaline solution of (β)-naphthol-(a)-di-sulphonic acid (Griess, B. 11, 2038). Orange needles or prisms. V. sol. water and alcohol, insol. ether. Salts. —A''H<sub>2</sub>Ba<sub>2</sub> 3aq: slightly soluble yellow needles. A''Ba<sub>2</sub> 5aq: nearly insoluble red crystalline pp.

Sulpho-carboxy-benzene-azo-oxy-naphthoic acid  $\text{C}_6\text{H}_4(\text{SO}_3\text{H})(\text{CO}_2\text{H})\text{N}_2\text{C}_{10}\text{H}_7(\text{OH})(\text{CO}_2\text{H})$ . Prepared by the action of diazosulphobenzoic acid on an alkaline solution of (a)-oxy-naphthoic acid (Griess, B. 11, 2199). Brown microscopic needles or leaflets. Sl. sol. water.

Sulpho-naphthalene-azo-(β)-naphthol-di-sulphonic acid  $\text{C}_{10}\text{H}_7(\text{SO}_3\text{H})_2\text{N}_2\text{C}_{10}\text{H}_7(\text{OH})(\text{SO}_3\text{H})_2$ . Grim-on dye (Stebbins, A. C. J. 2, 416).

Sulpho-toluene-azo-toluene-sulphonic acid  $[2:4:1] \text{C}_6\text{H}_4\text{Me}(\text{SO}_3\text{H})_2\text{N}_2\text{C}_6\text{H}_4\text{Me}(\text{SO}_3\text{H})$  [1:2:4]. From potassium *o*-toluidine sulphate (of Gerver) and KMnO<sub>4</sub> (Kornatzki, A. 221, 183). Small red prisms, grouped in tables, very soluble in water and in alcohol. K<sub>2</sub>A'': red plates grouped in clumps. —BaA'' aq. —CaA'' 3aq. —PbA'' aq.

Chloride. [218°]. Red needles (from C<sub>12</sub>H<sub>5</sub>).

Amide. [250°]. Tables (from aqueous NH<sub>3</sub>).

Sulpho-toluene-azo-toluene-sulphonic acid  $[2:5:1] \text{C}_6\text{H}_4\text{Me}(\text{SO}_3\text{H})_2\text{N}_2\text{C}_6\text{H}_4\text{Me}(\text{SO}_3\text{H})$  [1:2:5]. Azo-toluene-disulphonic acid. From *o*-nitro-toluene sulphonic acid, zinc dust, and KOHAq (Neale, A. 203, 74); or from *o*-toluidine sulphonic acid of Hayduck and KMnO<sub>4</sub> (Kornatzki, A. 221, 181). Salts. —BaA'' 1aq. —K<sub>2</sub>A'' 2½aq. —CaA'' 5aq. —PbA'' 4aq.

Chloride. [220°]. Red prisms.

Amide. [300°]. Red powder.

Sulpho-toluene-azo-toluene-sulphonic acid  $[4:6:1] \text{C}_6\text{H}_4\text{Me}(\text{SO}_3\text{H})_2\text{N}_2\text{C}_6\text{H}_4\text{Me}(\text{SO}_3\text{H})$  [1:4:6]. From potassium *p*-toluidine sulphate and KMnO<sub>4</sub> (Kornatzki, A. 221, 182).

Salt. —BaA'' 3aq.

Sulpho-toluene-azo-toluene-sulphonic acid  $[4:5:1] \text{C}_6\text{H}_4\text{Me}(\text{SO}_3\text{H})_2\text{N}_2\text{C}_6\text{H}_4\text{Me}(\text{SO}_3\text{H})$  [1:4:5]. From *p*-nitro-toluene *o*-sulphonic acid, KOHAq, and zinc dust (Neale, A. 203, 80); or from potassium *p*-toluidine sulphate and KMnO<sub>4</sub>.

K<sub>2</sub>A'' 3aq. —CaA'' 3aq. —PbA'' aq. —BaA'' 2aq.

Chloride. [194°]. Red crystals.

Amide. [270°]. Yellow.

*Para*-Sulpho-toluene-azo-toluene-azo-sulphonic acid  $\text{SO}_3\text{H}(\text{CH}_2)_2\text{C}_6\text{H}_4\text{N}_2\text{C}_6\text{H}_4\text{N}_2\text{C}_6\text{H}_4\text{CH}_2\text{SO}_3\text{H}$

Formation. —1. From C<sub>12</sub>H<sub>11</sub>(NO<sub>2</sub>)CH<sub>2</sub>SO<sub>3</sub>H by boiling with zinc dust and KOH or Ba(OH)<sub>2</sub>. —2. From C<sub>12</sub>H<sub>11</sub>(NH<sub>2</sub>)CH<sub>2</sub>SO<sub>3</sub>K and KMnO<sub>4</sub> (Mohr, A. 221, 223). Salts. —K<sub>2</sub>A'' 3aq: orange plates. —BaA'' 1½aq. —Ag<sub>2</sub>A'' aq.

Chloride. [149°].

Sulpho-xylene-azo-di-bromo-naphthol  $\text{C}_{10}\text{H}_6\text{Me}_2(\text{SO}_3\text{H})\text{N}_2\text{C}_{10}\text{H}_6\text{Br}_2(\text{OH})$ . From *p*-diazoxylene sulphonic acid and di-bromo-(a)-naphthol (Stebbins, jun., A. C. J. 2, 446). Sol. hot water, forming a scarlet solution.

Sulpho-xylene-azo-(a)-naphthol  $\text{C}_{10}\text{H}_6\text{Me}_2(\text{SO}_3\text{H})\text{N}_2\text{C}_{10}\text{H}_7\text{OH}$ . From *p*-diazox-

xylylene sulphonie acid and (a)-naphthol (Stebbins, jun., *A. C. J.* 2, 446). Brown dye; sol. water.

**Sulpho-*m*-xylylene-azo-( $\beta$ )-naphthol**

[1:3:6:4]  $C_8H_4Me_2(SO_3H)-N_2-C_{10}H_7(OH)$ . Formed by the action of diazo-*m*-xylylene sulphonie acid (from *m*-xylidine sulphonie acid) upon an alkaline solution of ( $\beta$ )-naphthol (Nörling a. Kohn, *B.* 19, 139). Metallic green crystals. Sl. sol. cold water. Dyes wool and silk from an acid bath a yellowish shade of scarlet.

**Salts.**— $A'Na^+$ : red soluble plates.— $A'Ba$ : sl. sol. hot water.

**Sulpho-xylylene-azo-( $\beta$ )-phenanthrol.** From *p*-diazoxylene sulphonie acid and ( $\beta$ )-phenanthrol (Stebbins, *A. C. J.* 2, 446). Reddish-brown dye.

**Sulpho-xylylene-azo-resorcin v. Di-oxy-benzene-azo-xylylene sulphonie acid.**

**Sulpho-xylylene-azo-xylylene sulphonie acid** [2:4:5:1]  $C_8H_4Me_2(SO_3H)-N_2-C_8H_4Me_2(SO_3H)$  [1:2:4:5]. Formed by oxidising (1, 3, 6, 4)-xylidine sulphonie acid with dilute  $KMnO_4$  (Jacobsen a. Ledderhage, *B.* 16, 194); or by reducing (6, 1, 3, 4)-nitro-xylylene sulphonie acid with zinc-dust and  $NaOH$  (Limpricht, *B.* 18, 2191). Orange plates; v. sol. water; sl. sol. acids.

**Salts.**— $K_2A''4aq.$ — $KHA''4aq.$

**Chloride.** [86°]; red crystals.

**Amide.** [174°].

***m*-Thio-sulpho-benzene-azo-benzene-sulphonie acid** [3:1]  $(HSO_3)C_6H_4.N_2.C_6H_4(SO_3H)$  [1:3] [below 100°]. A solution of the barium thio-sulphate gives, on evaporation, S and the salt of the present acid. This salt forms red crusts which are sparingly soluble in water, but are converted by boiling  $Na_2CO_3$  into the soluble Na salt, whence  $HCl$  separates the free acid as a bulky flocculent pp. hardly soluble in water, but resinsified by boiling with it. It is soluble in alcohol. Oxidised by  $KMnO_4$  to  $N_2(C_6H_4SO_3K)_2$ .

**Salts.**— $BaA''$  (dried at 140°)— $K_2A''$ — $Na_2A''$  aq.— $PbA''$  (dried at 130°).

**Isomer.**—Ammonia converts the acid into a brown amorphous base, isomeric with it (Limpricht, *B.* 18, 1472; Bauer, *A.* 229, 360).

***m*-Thio-sulpho-benzene-azo-benzene-*m*-thio-sulphonie acid**

[3:1]  $HSO_3.C_6H_4.N_2.C_6H_4.SO_3SH$  [1:3] [91°–93°]. From its salts by adding *glacial* acetic acid. A voluminous yellow pp. insol. water or alcohol, and resinsified when boiled with them (Limpricht, *B.* 18, 1471; Bauer, *A.* 229, 358).

**Barium salt.**— $BaA''$  5aq. One of the products of the action of baric sulphhydrate upon the chloride of sulpho-benzene-azo-benzene-sulphonie acid (*q. v.*). V. sol. hot water, sl. sol. cold water, nearly insoluble in alcohol. Yellow ammoniac sulphide slowly converts it into the corresponding hydrazo-compound.

**$Na_2A''$  aq.** Its solutions give amorphous pps. with salts of Cu, Pb, Ag and  $Fe'''$ .

***p*-Thio-sulpho-benzene-azo-benzene-thio-sulphonie acid**

[4:1]  $C_6H_4(SO_3SH)-N_2-C_6H_4(SO_3SH)$  [1:4]. Yellow amorphous solid. Sl. sol. water and alcohol. Formed by the action of a saturated aqueous solution of  $Ba(SH)_2$  upon the chloride of sulpho-benzene-azo-benzene-sulphonie acid.  $Na_2A''$  aq.: very soluble yellow warty crystals.

— $BaA''$ : yellow warty crystals, sol. hot water (Limpricht, *B.* 18, 1474; Bauer, *A.* 229, 368).

***p*-Toluene-azo-aceto-acetic acid**

[4:1]  $C_6H_4(CH_3)-N_2-CH(CO.CH_3).CO_2H$  [189°].

**Ethyl ether  $A'Et$ :** [70°]; yellow needles.

Formed by the action of *p*-diazotoluene chloride on an alcoholic solution of sodio-acetoacetic ether (Züblin, *B.* 11, 1419; Richter a. Münzer, *B.* 17, 1929).

***p*-Toluene-azo-acetone**

[4:1]  $C_6H_4(CH_3)-N_2-CH_2.CO.CH_3$  [115°].

**Formation.**—1. By heating *p*-toluene-azo-aceto-acetic ether with a dilute alcoholic solution of  $NaOH$ .—2. By heating *p*-toluene-azo-aceto-acetic acid above its melting-point,  $CO_2$  being evolved (Richter a. Münzer, *B.* 17, 1929). Yellow needles. Sl. sol. water.

**Toluene-azo-bromo-toluene**

$C_6H_4Me-N_2-C_6H_4BrMe$ . **Bromo-azo-toluene.** [136°] (P); [138–5°] (J. a. E.). Formed by brominating *p*-toluene-azo-toluene (Petrie, *B.* 6, 557; Janovsky a. Erb, *B.* 20, 363). Golden plates or needles. Reduces to a hydrazo-compound [119°].

**Toluene-azo-chloro-toluene**

[4:1]  $C_6H_4Me.N_2.C_6H_4MeCl$  [1:5:2]. [97°]. Formed by the action of cuprous chloride upon diazotised *p*-toluene-*p*-azo-toluidine (from *p*-toluidine); yield, 20 p.c. of theoretical. Brown plates. V. sol. alcohol, ether, and benzene (Montha, *B.* 19, 3026).

***p*-Toluene-azo-*p*-cresol**

[4:1]  $C_6H_4(CH_3)-N_2-C_6H_3(CH_3)(OH)$  [1:5:2] [113°]. Obtained by the action of *p*-diazotoluene chloride on an alkaline solution of *p*-cresol. It is also formed by diazotising *p*-toluene-azo-*p*-toluidine  $C_6H_4(CH_3)-N_2-C_6H_4(CH_3)(NH_2)$  and boiling the product with water (Nörling a. Kohn, *B.* 17, 354). Reddish needles or yellow tables. V. sol. ether, benzene, and hot alcohol.

**Acetyl derivative** [91°], yellow needles.

**Benzoyl derivative** [95°], small yellow needles.

***o*-Toluene-azo-ethyl-( $\beta$ )-naphthyl-amine**

[2:1]  $C_6H_4(CH_3)-N_2-C_{10}H_7(NHET)$  [1:2]. [132°]. Formed by heating ethyl-( $\beta$ )-naphthyl-nitrosamine with an acetic acid solution of *o*-toluidine (Henriques, *B.* 17, 2670).

***p*-Toluene-azo-ethyl-( $\beta$ )-naphthyl-amine**

[4:1]  $C_6H_4(CH_3).N_2.C_{10}H_7(NHET)$  [1:2]. [113°]. Formed by heating ethyl-( $\beta$ )-naphthyl-nitrosamine with an acetic acid solution of *p*-toluidine (Henriques, *B.* 17, 2670).

***o*-Toluene-*p*-azo-(a)-naphthol**

[2:1]  $C_6H_4Me.N_2.C_{10}H_7(OH)$  [1:4]. (***a*-Naphthoquinone-*o*-tolyl-hydrazide.** [146°].

**Formation.**—1. From *o*-diazotoluene and (*a*)-naphthol.—2. From (*a*)-naphthoquinone and *o*-tolyl-hydrazine.

**Properties.**—Red glistening needles. V. sol. alcohol, acetic acid, and benzene, less readily in benzoline.  $HNO_3$  converts it into di-nitro-(*a*)-naphthol. With  $HCl$  and  $HBr$  it gives dark blue metallic-glistening salts. Dissolves in dilute  $NaOH$ .

**Methyl ether**  $C_{11}H_{13}N_2(OMe)$  [93°]; reddish-brown glistening needles; easily soluble in ordinary solvents.

**Ethyl ether**  $C_{11}H_{13}N_2(OEt)$  [94°]; red plates or dark thick needles (Zincke a. Rathgen, *B.* 19, 2488).

**p-Toluene-p-azo-( $\alpha$ )-naphthol**  
[4:1]  $C_9H_7Me.N_2.C_{10}H_7(OH)$  [144]. ( $\alpha$ )-Naphtho-quinone-p-tolyl-hydrazide. [208°].

**Formation.**—1. From p-diazo-toluene and  $\alpha$ -naphthol.—2. From ( $\alpha$ )-naphthoquinone and p-tolyl-hydrazine.

**Properties.**—Metallic-glistening dark-red pangles. V. sol. acetone, aniline, and hot nitrobenzene, sl. sol. alcohol, acetic acid, and benzene. Dissolves in dilute NaOH.  $HNO_3$  converts it into di-nitro-( $\alpha$ )-naphthol. Not attacked by bromine in acetic acid solution. With mineral acids it forms salts which separate in bluish-green metallic-glistening plates. By heating with baryta-water it is rendered insoluble in alkalis.— $B^*HCl$ .— $B^*HBr$ .

**Methyl ether**  $C_9H_7Me.N_2(OMe)$  [104°].

**Ethyl ether**  $C_9H_7Me.N_2(OEt)$  [127°], large red crystals or red needles.

**Acetyl derivative**  $C_9H_7Me.N_2(OAc)$  [102°], fine yellowish needles (from benzoline) (Zincke a. Rathgen, B. 19, 2486).

**o-Toluene-o-azo-( $\alpha$ )-naphthol**

[2:1]  $C_8H_4Me.N_2.C_{10}H_6(OH)$  [2:1] or

$\begin{array}{c} O \\ | \\ C_9H_7Me.HN_2 \end{array} C_{10}H_6$ . ( $\beta$ )-Naphtho-quinone-o-tolyl-hydrazide. [156°]. Formed by the action of o-tolyl-hydrazine upon ( $\beta$ )-naphthoquinone. Glistening red plates. Easily soluble in ordinary solvents.  $HNO_3$  converts it into di-nitro-( $\alpha$ )-naphthol. Bromine gives a di-bromo-derivative [254°] (Zincke a. Rathgen, B. 19, 2492).

**p-Toluene-o-azo-( $\alpha$ )-naphthol**

[4:1]  $C_8H_4Me.N_2.C_{10}H_6(OH)$  [2:1] or

$\begin{array}{c} O \\ | \\ C_9H_7Me.HN_2 \end{array} C_{10}H_6$ . ( $\beta$ )-Naphtho-quinone-p-tolyl-hydrazide. [145°]. Formed by the action of p-tolyl-hydrazine upon ( $\beta$ )-naphthoquinone. Red slender glistening needles. V. sol. alcohol, benzene, and acetic acid, sparingly in benzoline. By  $SnCl_2$  it is reduced to ( $\beta$ )-amido-( $\alpha$ )-naphthol and p-toluidine.  $HNO_3$  converts it into di-nitro-( $\alpha$ )-naphthol. Bromine gives a di-bromo-derivative [236°] (Zincke a. Rathgen, B. 19, 2491).

**p-Toluene-o-azo-( $\beta$ )-naphthol**

[4:1]  $C_8H_4Me.N_2.C_{10}H_6(OH)$  [1:2] or

$\begin{array}{c} O \\ | \\ C_9H_7Me.N_2.H \end{array} C_{10}H_6$ . Formed by combination of p-diazo-toluene with ( $\beta$ )-naphthol. Thick red needles or tables. V. sol. alcohol, benzene, acetic acid, and acetone. Insoluble in cold dilute NaOH. With acids it forms unstable salts. Bromine in acetic acid converts it into a di-bromo-derivative [190°].  $HNO_3$  gives di-nitro-( $\beta$ )-naphthol (Zincke a. Rathgen, B. 19, 2490).

**o-Toluene-o-azo-( $\beta$ )-naphthol**

[3:1]  $C_8H_4Me.N_2.C_{10}H_6(OH)$  [1:2] or

$\begin{array}{c} O \\ | \\ C_9H_7Me.N_2.H \end{array} C_{10}H_6$ . Formed by combination of o-diazo-toluene with ( $\beta$ )-naphthol. Fine red needles or plates. Insol. cold dilute NaOH. With acids it forms unstable salts.  $HNO_3$  converts it into di-nitro-( $\beta$ )-naphthol. Bromine forms a mono-bromo-derivative [167°]. Zincke a. Rathgen, B. 19, 2491; Fischer, B. 20, 580).

**p-Toluene-azo-( $\beta$ )-naphthol disulphonic acid**

$H_3Me.N_2-C_{10}H_6(OH)(SO_3H)_2$ . From sodium-( $\beta$ )-naphthol disulphonate and p-diazo-toluene

nitrate (Stebbins, A. C. J. 2, 236; C. N. 42, 44). Red leaflets, v. sol. water. Scarlet dye. The corresponding o-compound dyes yellow, the m-compound, redder.

**p-Toluene-azo-( $\alpha$ )-naphthylamine**

[4:1]  $C_8H_4(CH_3)-N_2-C_{10}H_7NH_2$  [144]. [145°]. Prepared by the action of p-diazo-toluene sulphate on ( $\alpha$ )-naphthylamine (Weselsky a. Benedikt, B. 12, 229). Red leaflets; insol. water.— $B^*H_2SO_3aq$ : steel-blue needles.

**o-Toluene-azo-nitro-ethane**

[2:1]  $C_8H_4Me-N_2-CH(NO_2)CH_3$  [88°]. From o-diazo-toluene nitrate and potassium nitro-ethane (Barbieri, B. 9, 387). Unstable orange needles.— $NaA'$ : golden spangles.

**p-Toluene-azo-nitro-ethane**. [133°]. Prepared like the preceding (B.). Orange prisms with steel-blue lustre. Its alkaline solutions are deep red.

**Toluene-azo-nitro-toluene**

$C_8H_4Me-N_2-C_6H_4(NO_2)Me$ . Nitro-azo-toluene [114°]. Among the products of the nitration of toluene-azo-toluene dissolved in glacial acetic acid (Janowsky a. Erb, B. 20, 363). Orange monoclinic needles (from 90 p.c. alcohol).

**Toluene-azo-nitro-toluene**, [76°]. From toluene-azo-toluene and  $HNO_3$  (S.G. 1-4) (Petricoff, B. 6, 557).

**o-Toluene-azo-orein**

$C_8H_4Me-N_2-C_6H_4Me(OH)_2$  [203°–206°]. From o-diazo-toluene and orein (Seichilone, G. 12, 223). Red-brown crystals.

**p-Toluene-azo-thymol sulphonic acid**

$C_8H_4(CH_3)-N_2-C_6H_4(CH_3)(CH_3)(HSO_3)OH$ . Prepared by the action of p-diazo-toluene-chloride on sodium thymol-sulphonate.— $AA'$ : slender yellow needles; sol. alcohol and hot water, almost insoluble in cold water (Stebbins, B. 14, 2795).

**o-Toluene-o-azo-toluene**

[2:1]  $Me.C_6H_4-N_2-C_6H_4.Me$  [1:2]. o-Azo-toluene [55°].

**Preparation.**—1. By distilling o-nitro-toluene with alcoholic potash; or by reducing it with zinc-dust and alcoholic NaOH (Schultz, B. 17, 497). Cannot be prepared by reducing o-nitro-toluene in alcoholic solution with sodium-amalgam (Perkin).—2. From o-toluidine and  $KMnO_4$  (Hoogewerf a. van Dorp, B. 11, 1203).

**Properties.**—Dark red trimetric prisms;  $a:b:c = 2.225:1.1708$ . Volatile with steam. Gives a mono-nitro-derivative [c. 67°], a di-nitro-derivative, [142°], and a tri-nitro-derivative that decomposes before melting (Petricoff).

**m-Toluene-m-azo-toluene**

[3:1]  $Me.C_6H_4-N_2-C_6H_4.Me$  [1:3]. m-Azo-toluene [51°] (G.); [55°] (B.). From m-nitro-toluene by boiling with alcoholic KOH (Goldschmidt, B. 11, 1621), or by treatment with zinc-dust and alcoholic KOH (Barsilowsky, B. 10, 2097; A. 207, 114). Orange-red trimetric tables,  $a:b:c = 85:1:54$ . V. sol. alcohol.

**p-Toluene-p-azo-toluene. p-Azo-toluene**

[4:1]  $Me.C_6H_4-N_2-C_6H_4.Me$  [1:4]. [144°].

**Formation.**—From p-toluidine and  $CrO_3$  in glacial acetic acid; or by treating a solution of p-toluidine in chloroform with bleaching-powder (B. Schmitt, J. pr. [2] 18, 198). Or by oxidising p-toluidine with  $H_2O_2$  (Leeds, B. 14, 1882), or benzoyl peroxide. Cannot be prepared by distilling p-nitro-toluene with alcoholic potash

(Perkin), for by such treatment a red condensation product is obtained which on further reduction gives di-*ami* lo-di-phenyl-ethylene [227°]. (Bender a. Schultz, *B.* 19, 3237).

**Preparation.**—*p*-Nitro-toluene (20g.) in alcohol is treated with sodium-amalgam added gradually, the mixture being frequently cooled. The brown solid that separates is crystallised from glacial acetic acid (Perkin, *C. J.* 37, 554, cf. Jaworsky, *J. pr.* 94, 283; Werigo, *Z.* 1864, 640; Alexejeff, *Z.* 1866, 269; Melms, *B.* 3, 549; Schultz, *B.* 17, 472).

**Properties.** Red trimetric needles. *V.* sol. alcohol and ligroin, sl. sol. alcohol. Slowly reduced to hydrazo-toluene by ammonium sulphide. In alcoholic solution it is reduced by  $\text{SnCl}_2$  and  $\text{HCl}$  to toluidine [91°]. (*S.*) Nitric acid forms a mono-nitro-derivative, [76°], a dinitro-derivative [110°], and a tri-nitro-derivative [201°] (Petrieff).

#### *o*-Toluene-*m*-azo-toluene

[2:1]  $\text{C}_6\text{H}_4(\text{CH}_3)-\text{N}_2-\text{C}_6\text{H}_4(\text{CH}_3)$  [1:3]. Obtained by diazotising *o*-toluene-azo-*o*-toluidine (from *o*-toluidine) and treating the diazo-compound with alcohol (Schultz, *B.* 17, 470). Red oil. Volatile with steam. *V.* sol. alcohol and ether. By  $\text{SnCl}_2$  and  $\text{HCl}$  in alcoholic solution it is converted into an unsymmetrical toluidine.

#### *m*-Toluene-*p*-azo-toluene

[4:1]  $\text{C}_6\text{H}_4(\text{CH}_3)-\text{N}_2-\text{C}_6\text{H}_4(\text{CH}_3)$  [1:3]. [58°]. **Formation.**—1. By the action of zinc-dust and alcohol upon *o*-diazo-toluene-azo-toluene.—2. By the action of  $\text{Ag}_2\text{O}$  and alcohol upon the compound  $\text{C}_6\text{H}_4\text{N}_2$ , the reduction-product of *o*-diazo-toluene-azo-toluene (Zincke a. Lawson, *B.* 19, 1458). Brownish-red plates. *V.* sol. alcohol, ether and benzene.

#### *o*-Toluene-azo-toluidine

[2:1]  $\text{C}_6\text{H}_4(\text{CH}_3)-\text{N}_2-\text{C}_6\text{H}_4(\text{CH}_3)(\text{NH}_2)$  [1:3:4] [100°]. Formed by passing nitrous acid gas into *o*-toluidine (Nietzki, *B.* 10, 662). Trimetric crystals, *abz*:*c* = 1.0116:1.1:3.268. Heated with aniline hydrochloride and alcohol at 160° it forms a red dye resembling safranin.

**Salts.**— $\text{B}^+\text{HCl}^-$  orange tables.— $\text{B}^+\text{H}_2\text{PtCl}_6^-$ .

#### Acetyl derivative

$\text{C}_6\text{H}_4-\text{N}_2-\text{C}_6\text{H}_4(\text{NHAc})$ . [185°]. Slender red needles, *v.* sol. alcohol (Schultz, *B.* 17, 469).

#### *m*-Toluene-azo-*m*-toluidine

[3:1]  $\text{C}_6\text{H}_4\text{Me}-\text{N}_2-\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)$  [1:2:4]. [80°]. Formed by treating an alcoholic solution of *m*-toluidine with nitrous acid gas (Nietzki, *B.* 10, 1155). Golden needles.— $\text{B}^+\text{HCl}^-$ .— $\text{B}^+\text{H}_2\text{PtCl}_6^-$ . Gives *p*-tolylene diamine, [64°], on reduction.

#### *p*-Toluene-azo-*o*-toluidine

[4:1]  $\text{C}_6\text{H}_4\text{Me}-\text{N}_2-\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)$  [1:3:4]. [128°]. From *p*-diazo-toluene toluidine and *o*-toluidine hydrochloride (Nietzki, *B.* 10, 832). Gives *p*-tolylene-diamine, [61°], on reduction. Heated with aniline hydrochloride it forms a violet dye. **Salts.**— $\text{B}^+\text{HCl}^-$ .— $\text{B}^+\text{H}_2\text{PtCl}_6^-$ .

#### *p*-Toluene-azo-*m*-toluidine

[4:1]  $\text{C}_6\text{H}_4\text{Me}-\text{N}_2-\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)$  [1:2:4]. [127°]. From *p*-diazo-toluene toluidine and *m*-toluidine hydrochloride in alcoholic solution (Nietzki, *B.* 10, 1156). Large yellow plates. Gives *p*-tolylene-diamine [64°] on reduction.

**Salts.**— $\text{B}^+\text{HCl}^-$ .— $\text{B}^+\text{H}_2\text{PtCl}_6^-$ .

#### *p*-Toluene-azo-*p*-toluidine

[4:1]  $\text{C}_6\text{H}_4\text{Me}-\text{N}_2-\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)$  [1:5:2] or  $\text{NH}$

$\text{C}_6\text{H}_4\text{Me.N.H}$   $\text{C}_6\text{H}_4\text{Me}$ . [119°]. *o*-Amido-azo-toluene. Toluene-hydrazimido-toluene. Prepared by heating *p*-diazo-toluene-*p*-toluidine (diazo-amido-toluene), dissolved in 5 or 6 times its weight of melted *p*-toluidine, with *p*-toluidine hydrochloride (1 mol.) at 65° for 12 hours. Orange-red glistening needles. *V.* sol. hot alcohol, acetic ether, and benzene. On reduction it gives *p*-toluidine and tolylene-*o*-diamine.  $\text{CrO}_3$  oxidises it in acetic acid solution to toluene-azimido-toluene  $\text{C}_6\text{H}_4-\text{N}_2-\text{C}_6\text{H}_4$  (Zincke, *B.* 18, 1342). Heated with *p*-toluidine hydrochloride and *p*-toluidine at 100° it gives a body  $\text{C}_{12}\text{H}_{14}\text{N}_2$ , analogous to azophenine which forms flat red needles. Heated to a higher temperature dyestuffs of the induline series are formed. It is converted into eurhodine  $\text{C}_{12}\text{H}_{14}\text{N}_2$  by heating with (*a*)-naphthylamine hydrochloride (Witt, *C. J.* 49, 393). The salts of *o*-amido-azo-*p*-toluene are yellow in the solid state, but dissolve to green solutions.— $\text{B}^+\text{HCl}^-$ : slender light-yellow needles.

**Acetyl derivative.** [157°]; yellow felted needles.

**Benzoyl derivative.** [135°]; orange-yellow needles (Witt a. Nötling, *B.* 17, 77).

**Disulphonic acid**  $\text{C}_{12}\text{H}_{14}\text{N}_2(\text{SO}_3\text{H})_2$ . Formed by sulphonating with fuming  $\text{H}_2\text{SO}_4$  (N. a. W.). Greyish white needles. Is a yellow dyestuff of redder shade than 'acid yellow.'— $\text{BaA}^+\text{4aq}^-$ : brownish-red crystalline powder.

#### *p*-Toluene-azo-tolylene-diamine

[4:1]  $\text{C}_6\text{H}_4\text{Me}-\text{N}_2-\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)$  [1:3:4:6]. [183°]. From *p*-diazo-toluene nitrate and tolylene-*m*-diamine (Hofmann, *B.* 10, 218). Orange needles, *v.* sol. alcohol, insol. water.— $\text{B}^+\text{HCl}^-$ .— $\text{B}^+\text{H}_2\text{PtCl}_6^-$ .

**Xylene-azo-( $\beta$ )-naphthol-( $\beta$ )-sulphonic acid.** Diazo-xylene does not combine with Rumpf's ' $\alpha$ '-sulphonic acid of ( $\beta$ )-naphthol in dilute alkaline solution, although some other diazo-compounds (such as diazo-benzene) do combine with it under the same conditions. If, however, the solution is very concentrated, the combination with diazo-xylene takes place. The product forms red needles, dissolves in  $\text{H}_2\text{SO}_4$  with a red colour, and dyes wool a somewhat yellower shade than the compound from Schäfer's ' $\beta$ '-acid (Schultz, *B.* 17, 461).

#### Xylene-azo-thymol-sulphonic acid

$\text{C}_6\text{H}_4(\text{CH}_3)_2-\text{N}_2-\text{C}_6\text{H}_4(\text{CH}_3)(\text{C}_2\text{H}_5)(\text{HSO}_3)\text{OH}$ . Slender yellow needles. Prepared by the action of diazo-xylene chloride on sodium thymol-sulphonate.— $\text{A}^+\text{Ba}^-$ : small yellow needles or plates (Stebbins, *B.* 14, 2795).

#### Xylene-azo-xylene

$\text{C}_6\text{H}_4(\text{CH}_3)_2-\text{N}_2-\text{C}_6\text{H}_4(\text{CH}_3)_2$ . *Azo-xylene* [126° corr.] Formed by reduction of nitro-*m*-xylene with sodium-amalgam or with zinc-dust and alcoholic  $\text{NaOH}$ ; very small yield. A better yield is obtained by oxidation of xylydine with alkaline potassium ferricyanide (Werigo, *Z.* 1864, 723; 1865, 312; Samonoff, *Bl.* [2] 39, 597; *J. R.* 1882, 327; Schultz, *B.* 17, 476). Red needles. Sol. hot alcohol. It does not appear to give a dixylyl base by treatment with  $\text{SnCl}_4$  and  $\text{HCl}$  in alcoholic solution.

***m*-Xylene-o-azo-*m*-xylidine**  
 [3:4:1]  $C_6H_4Me_2-N_2-C_6H_4Me_2(NH_2)$  [1:3:5:6]

or 
$$\begin{array}{c} NH \\ | \\ C_6H_4Me_2-NH-C_6H_4Me_2 \end{array}$$
 ***o*-Amido-azo-*m*-xylene.** [78°]

**Preparation.**—Diazo-*m*-xylene-*m*-xylide, prepared by adding a solution of 1 mol. of sodium nitrite to a mixture of 1 mol. of *m*-xylidine  $C_6H_4Me_2NH_2$  [1:3:4] and 1 mol. of its hydrochloride, is dissolved in *m*-xylidine and gently warmed for a long time with about 5 p.c. of *m*-xylidine hydrochloride. The mixture is then acidified with dilute HCl, the precipitated hydrochloride is filtered off, washed with water, alcohol, and ether, basified, and crystallised from alcohol or benzene; the yield is 70 p.c. to 80 p.c. of theoretical. Orange plates. V. sol. benzene, and hot alcohol, v. sl. sol. water.

**Reactions.**—On reduction it yields *m*-xylidine and *m*-xylylene-*o*-diamine  $C_6H_4Me_2(NH_2)_2$  [1:3:5:6].

**Salts.**—B'HCl: yellow crystalline powder, dissolves sparingly in alcohol with a green colour, soluble in phenol with a splendid green colour (Nölting a. Forel, B. 18, 2682).

***m*-Xylene-*p*-azo-*m*-xylidine**  
 [2:6:1]  $C_6H_4Me_2-N_2-C_6H_4Me_2(NH_2)$  [1:3:5:4]  
 [78°]. Yellow plates. Easily soluble in alcohol and benzene. Prepared from *m*-xylidine  $C_6H_4Me_2NH_2$  [1:3:2] by the same method as that described under *m*-xylene-*o*-azo-*m*-xylidine.

**Salts.**—J', H, Cl, PtCl: red crystalline powder. The hydrochloride dissolves in phenol or alcohol with a red colour (Nölting a. Forel, B. 18, 2684).

***m*-Xylene-*p*-azo-*o*-xylidine**  
 [3:5:1]  $C_6H_4Me_2-N_2-C_6H_4Me_2(NH_2)$  [1:2:6:1]  
 [95°]. Prepared from *m*-xylidine  $C_6H_4Me_2NH_2$  [1:3:5] by the same method as that described for *m*-xylene-*o*-azo-*m*-xylidine. Yellow plates. On reduction it gives symmetrical *m*-xylidine and *m*-xylylene-*p*-diamine  $C_6H_4Me_2(NH_2)_2$  [1:3:2:5]. The hydrochloride dissolves in phenol with a violet-red colour (Nölting a. Forel, B. 18, 2684).

***o*-Xylene-*p*-azo-*o*-xylidine**  
 [2:3:1]  $C_6H_4Me_2-N_2-C_6H_4Me_2(NH_2)$  [1:2:3:4]  
 [111°]. Prepared from *o*-xylidine  $C_6H_4Me_2NH_2$  [1:2:3] by the same method as that described under *m*-xylene-*o*-azo-*m*-xylidine (Nölting a. Forel, B. 18, 2684). Glistening yellow plates (from alcohol or benzene). On reduction it yields *o*-xylidine and *o*-xylylene-*p*-diamine  $C_6H_4Me_2(NH_2)_2$  [1:2:3:6]. The hydrochloride dissolves in phenol with a red colour.

***m*-Xylene-*p*-azo-*p*-xylidine**  
 [2:4:1]  $C_6H_4Me_2-N_2-C_6H_4Me_2(NH_2)$  [1:2:5:4]  
 [111°]. Red plates.

**Preparation:** 50 c.c. of a solution of sodium nitrite containing 227 grms.  $NaNO_2$  per litre are added to a mixture of 20 grms. of *p*-xylidine and 26 grms. of hydrochloride of *m*-xylidine  $C_6H_4Me_2(NH_2)$  [1:3:4]; the diazoamide so formed is dissolved in 20 grms. of *p*-xylidine and gently warmed with 4 grms. of *p*-xylidine hydrochloride.

**Reactions.**—On reduction it yields *m*-xylidine and *p*-xylylene-*p*-diamine  $C_6H_4Me_2(NH_2)_2$  [1:4:2:5]. The hydrochloride dissolves in phenol with a red colour (Nietzki, B. 13, 470; Nölting a. Forel, B. 18, 2686).

***p*-Xylene-*p*-azo-*p*-xylidine**  
 [2:5:1]  $C_6H_4Me_2-N_2-C_6H_4Me_2(NH_2)$  [1:2:5:4].

[150°]. Red plates (from alcohol). Prepared from *p*-xylidine  $C_6H_4Me_2(NH_2)$  [1:4:5] by the same method as that described under *m*-xylene-*o*-azo-*m*-xylidine. On reduction it yields *p*-xylidine and *p*-xylylene-*p*-diamine  $C_6H_4Me_2(NH_2)_2$  [1:4:2:5]. The hydrochloride is red, and dissolves in phenol with a violet-red colour (Nölting a. Forel, B. 18, 2685).

***o*-Xylene-*o*-azo-*o*-xylidine**  
 [3:4:1]  $C_6H_4Me_2-N_2-C_6H_4Me_2(NH_2)$  [1:3:4:6] or  

$$\begin{array}{c} NH \\ | \\ C_6H_4Me_2-NH-C_6H_4Me_2 \end{array}$$
 [179°]. Yellow

plates. Sl. sol. alcohol. Prepared from *o*-xylidine  $C_6H_4Me_2(NH_2)$  [1:2:4] by the same method as that described under *m*-xylylene-*o*-azo-*m*-xylidine. On reduction it gives rise to *o*-xylidine and *o*-xylylene-*o*-diamine  $C_6H_4Me_2(NH_2)_2$  [1:2:4:5]. Its hydrochloride dissolves in phenol with a green colour (Nölting a. Forel, B. 18, 2685).

**DIAZO-COMPOUNDS.** A class of bodies formed by the action of nitrous acid upon primary amido-compounds:  $X.N_2H_2 + O.N.OH = X.N_2.OH + H_2O$ . They contain a pair of nitrogen atoms (Fr. *azote*) which are united to only one hydrocarbon radicle, whilst in the azo-compounds the  $N_2$  group is united to two hydrocarbon radicles  $X.N_2.Y$ . The diazo-radicles  $X.N_2$  cannot of course exist in the free state, but they occur as hydrates  $X.N_2.OH$ , chlorides  $X.N_2.Cl$ , amides  $X.N_2.NH_2$ , &c. For the sake of convenience reactions will usually be represented in this article as taking place with the hydrates.

The diazo-salts  $X.N_2A$  may be regarded as derived from the salts of amines  $X.NH_2A$  by the displacement of  $H_2$  by  $N$ . This may take place in two ways. According to Kekulé's view, which is that most generally adopted, both nitrogen atoms are trivalent:  $X.N:N.A$ . On the other hand, Blomstrand (*Chemie der Jetztzeit*, p. 272, and B. 8, 51) assumes that the nitrogen attached to the carbon is pentavalent:  $X.N_2A$ ;

Strecker (B. 4, 786) and Erlenmeyer (D. 7, 1110) also concur in this view. The reduction of diazo-compounds to hydrazines, which have the undoubted constitution  $X.NH.NH_2$ , E. Fischer (A. 190, 67) regards as a proof of the correctness of Kekulé's formula, since a body of the constitution  $X.N_2A$  would, he considers, give on

reduction  $X.NH_2$ . Crum Brown, however, has

pointed out in a private communication that this argument is fallacious, since the product of the reduction is not a hydrazine itself but a hydrazine-salt, and  $X.N_2A$ , by adding  $H_2$  to each

$N$ , would give the hydrazine salt  $X.NH_2A$ . He

considers the pentad  $N$  in the salts of hydrazines is most probably that connected to the hydrocarbon nucleus, in which case to explain their formation by adoption of Kekulé's formula would necessitate a shifting of the acid from one  $N$  to the other. The strongest argument against Kekulé's formula is that it represents diazo-salts, by not containing pentad nitrogen, as differently constituted to the salts of all other nitrogen bases. On the other hand, the

formula  $X.N.N.A$  would necessitate a rearrange-  
ment of the molecule in the formation of azo-  
compounds which undoubtedly have the con-  
stitution  $X.N:N.Y$ .

The simplest member of the series  $H.N_2.OH$  should be formed by the action of nitrous acid upon  $NH_3$ ; but it has not yet been obtained, probably by reason of its extreme instability. The best-known diazo-compounds are those derived from aromatic amines and amido-compounds, some of which are tolerably stable bodies. No diazo-compounds have at present been obtained from fatty amines, for, like the first member of the series,  $H.N_2.OH$ , they are so unstable that they are probably scarcely capable of existence, and at once break up into the alcohol and  $N_2$ . The only known fatty diazo-compounds are a few which have lately been prepared from fatty amido-ethers (e.g. glycecol). In their constitution they differ from the aromatic diazo-hydrates by containing a molecule of water less:  $(EtO_2C)CH_2.N_2.OH - H_2O = (EtO_2C)CH.N_2$ .

**A. Aromatic diazo-compounds.** The discovery of these bodies, and a large portion of our knowledge concerning them, are due to P. Griess (*A.* 106, 123; 113, 201; 117, 1; 120, 125; 121, 257; 137, 39; &c.), who, in a series of classical researches, opened up a field of investigation which in a few years has produced more discoveries of scientific interest and practical utility than almost any other branch of organic chemistry.

**Formation.**—1. By the action of nitrous acid (e.g.  $NOCl$ ,  $NOBr$ ,  $SO_3(OH)(NO_2)$ , zinc-dust and  $HNO_3$ , &c.) upon salts of primary amines.—2. By oxidation of primary hydrazines (R. Fischer, *A.* 190, 97).

**Preparation.**—The details vary very much with individual cases and the purposes for which the diazo-compounds are required. The amine can be dissolved in water, alcohol, acetic acid,  $HCl$ ,  $H_2SO_4$ , &c., and can then be treated with nitrous acid gas, sodium nitrite, or a nitrous ether. When required in the solid form, a common method is to mix the nitrate of the amine with a little water, cool in a freezing-mixture, and saturate with  $N_2O$  gas; the diazo-nitrate is then ppd. by addition of alcohol and ether. Diazo-compounds can also be isolated from their aqueous solutions by ppn. as platino-chlorides, perbromides, picrates, sulphites, &c. When the diazo-compound is required for a subsequent reaction it is seldom necessary to isolate it, but the compound can be prepared under the conditions suitable to the second reaction. For instance, when the diazo-compound is to be conjugated with an amine or phenol to form an azo-compound, the amine is usually dissolved in water containing 2 mol. of  $HCl$  for each  $NH_2$  group, cooled by addition of ice, and mixed with an aqueous solution of sodium nitrite (1 mol. to each  $NH_2$ ). The solution of the diazo-chloride thus prepared can be at once treated with a solution of the phenol or amine.

The diazotisation of simple amines, in not too dilute solutions, usually takes place quantitatively, and the reaction is tolerably rapid. For instance, the diazotisation of aniline in a 10 p.c. solution is so complete within an hour

that it forms the most accurate method of estimating nitrous acid or aniline (Green & Riddell, *C. N.* 49, 173; Green & Evershed, *S. C. I.* 1886, 633). The greater the molecular weight of the amine the slower and less complete is the diazotisation. The diazotisation of heavy amido-bodies is facilitated by the presence of a very large excess of mineral acid, using as little water as possible. Alcohol in many cases appears to have a contrary effect. Amido-groups cannot be diazotised unless combined with an acid: thus if the ordinary hydrochloride of *p*-phenylene diamine  $C_6H_4(NH_2)(NH_2)Cl$  is treated with  $HNO_3$  only one  $NH_2$  group is diazotised; but if a large excess of  $HCl$  is employed so that  $C_6H_4(NH_2)Cl_2$  is present, both  $NH_2$  groups are diazotised. The final products of the action of nitrous acid upon the mono-acid salts of diamines vary with the constitution of the latter. Thus *o*-phenylene diamine gives azimido-benzene:

*m*-Phenylene diamine gives tri-amido-azobenzene, thus:  $C_6H_4(NH_2)_2.N_2.OH + C_6H_4(NH_2)_2 = C_6H_4(NH_2)_2.N_2.C_6H_4(NH_2)_2 + H_2O$ . Whilst the diazo-compound  $C_6H_4(NH_2)_2.N_2.OH$  [1:4], from *p*-phenylene diamine, does not undergo any further transformation. The di-amido-benzoic acids react with nitrous acid in an exactly similar manner according as the  $NH_2$  groups are *o*, *m*, or *p* to each other (Griess, *B.* 17, 607).

**Properties.**—The diazo-salts are in general very unstable crystalline solids. When dry they often decompose with detonation, by heat or percussion. Their solutions slowly decompose at the ordinary temperature, more quickly on heating, with evolution of nitrogen. The hydrates are even more unstable than the salts, and have scarcely ever been isolated. The stability is increased by substitution in the nucleus; thus diazo-benzene-sulphonic acid is more stable than diazo-benzene. The diazo-derivatives of substituted phenols and of *o*- and *p*-sulphonic acids usually occur in the form of anhydro-compounds, e.g.

manner *o*-amido-diazo-compounds form inner amides (e.g. azimido-benzene, *v. supra*).

**Reactions.**—The diazo-compounds are extremely prone to undergo reactions; they play a most important part in organic syntheses and the determination of the constitution of isomeric aromatic compounds, by serving as an intermediate stage by means of which  $NH_2$  groups can be replaced by  $H$ ,  $OH$ ,  $Cl$ ,  $Br$ ,  $I$ ,  $F$ ,  $CN$ ,  $SH$ ,  $NO_2$ , &c. Their power of combining with amines and phenols to form azo-compounds renders them of great technical importance for the production of colouring-matters, for which purpose they are prepared in large quantities. The majority of their reactions consist in the evolution of  $N_2$ , and its replacement by the atom or group ( $Cl$ ,  $OH$ , &c.) previously united to it.

1. By heating the aqueous solution nitrogen is evolved, with formation of the corresponding phenol:  $X.N_2.OH = X.OH + N_2$ . The best method is to dissolve the amine in a considerable excess of dilute  $H_2SO_4$ , diazotise by adding  $NaNO_2$  to the iced solution, and finally heat to boiling.

2. When heated with strong alcohol the normal reaction appears to be the replacement of the  $N_2$  group by  $OEt$ , with formation of ethoxy-compounds (Wroblewski, *Z.* 6, 164; *B.* 17, 2703; Haller, *B.* 17, 1887; Hofmann, *B.* 17, 1917; Remsen, *Am.* 8, 243; *B.* 18, 65; Hayduck, *A.* 172, 212; Zander, *A.* 198, 25; Heffter, *A.* 221, 352; Payson, *A.* 221, 212, 363; Mohr, *A.* 221, 222; Hesse, *A.* 230, 293).

3. Under certain circumstances, at present undetermined, the reaction with alcohol takes a different course, resulting in the substitution of  $H$  for the  $N_2$  group, with production of the corresponding hydrocarbon together with aldehyde:

$X.N_2.OH + C_2H_5O = X.H + C_2H_5O + N_2 + H_2O$  (Griess). (a) The amido-compound is treated with a solution of nitrous acid in absolute alcohol, warmed till nitrogen comes off freely, allowed to cool, resaturated with  $N_2O_5$ , and the operation repeated until but little gas is evolved on heating (Neville a. Winther, *C. J.* 37, 452). (b) The amido-compound is dissolved in a considerable excess of conc.  $H_2SO_4$ , the solution diluted with a small quantity of water is cooled in a freezing-mixture, and the necessary quantity of solid sodium nitrite added. When diazotised the solution is poured in a thin stream into two or three times its bulk of alcohol; the mixture becomes warm enough to complete the reaction without further heating (Meldola, *C. J.* 1885, 507).

4. Mercaptan, when heated with diazo-compounds at  $170^\circ$ , behaves similarly to alcohol in reaction 3, causing the displacement of  $N_2$  by hydrogen with simultaneous formation of diethyl-di-sulphide (Schmitt a. Mittenzwey, *J. pr.* 126, 192).

5. The displacement of the  $N_2$  group by  $H$  is also effected by reduction to the corresponding hydrazine (*q. v.*), and treatment of this with  $CuSO_4$  or  $FeCl_3$  (*B.* 18, 90).

6. Reduction of a diazo-chloride with excess of  $SnCl_2$  also effects the displacement of  $N_2$  by  $H$ :  $X.N_2.Cl + SnCl_2 + H_2O = X.H + SnOCl_2 + HCl + N_2$ . A dilute aqueous solution of the diazo-chloride is treated with an excess of  $SnCl_2$  at  $0^\circ$ , and finally heated for two hours with an inverted condenser; the yield is good (Elfront, *B.* 17, 2329; Gasiorowski a. Wayss, *B.* 18, 337).

7. By treatment of a cold solution of a diazo-compound in conc.  $HCl$  with (2 mols. of)  $SnCl_2$ , the corresponding hydrazine (*q. v.*) is produced:  $X.N_2.Cl + 2SnCl_2 + 3HCl = X.NH.NH_2 + 2SnCl_4$ .

8. The reduction of the sulphates of diazo-compounds with  $SO_2$ , or with zinc-dust and acetic acid, also gives rise to hydrazines.

9. By heating with dilute  $HNO_3$  nitrated phenols are obtained (Nöting a. Wild, *B.* 18, 1338).

10. The platino-chlorides on distillation with dry  $Na_2CO_3$  yield the corresponding chloro-derivatives:  $(X.N_2.Cl)_2PtCl_2 = 2X.Cl + 2N_2 + PtCl_4$ .

11. The replacement of  $N_2$  by  $Cl$  is also effected by boiling the diazo-compound with fuming  $HCl$  in large excess:  $X.N_2.Cl = X.Cl + N_2$

(Griess, *B.* 18, 960; Gasiorowski a. Wayss, *B.* 18, 1936).

12. The same replacement is most readily effected by treating the aqueous solution of the diazo-chloride with cuprous chloride, which appears to act by intermediate formation of an addition product  $R.N_2.Cl.Cu.Cl_2$ . (a) A 10 p.c. solution of  $Cu_2Cl_2$  is prepared by adding 100 pts. of conc.  $HCl$  and 13 pts. of copper turnings to a hot solution of 25 pts. of crystallised  $CuSO_4$  and 12 pts. of  $NaCl$ , boiling till decolourised, and making up the weight to 203 pts. with conc.  $HCl$ . A dilute  $HCl$  solution of the diazo-compound is allowed to run slowly into the above solution (about 5 times the weight of the amine used) heated nearly to boiling; the product, if volatile, is distilled with steam, or it is separated and purified by crystallisation. (b) In most cases instead of separately diazotising the amine, its solution in dilute  $HCl$  can be mixed with about 5 pts. of the 10 p.c.  $Cu_2Cl_2$  solution, and a solution of the calculated quantity of  $NaNO_2$  run into the nearly boiling mixture (Sandmeyer, *B.* 17, 1633, 2650; Lellmann, *B.* 19, 810).

13. The perbromides (*q. v.*) of diazo-compounds, on heating by themselves, or with dry  $Na_2CO_3$ , or best by boiling with glacial acetic acid, yield bromo-derivatives:  $X.N_2.Br_2 = X.Br + Br_2 + N_2$  (Neville a. Winther, *C. J.* 37, 452).

14. The replacement of  $N_2$  by  $Br$  is also effected by boiling the diazo-compound with fuming  $HBr$  in large excess:  $X.N_2.Br = X.Br + N_2$  (Griess, *B.* 18, 960; Gasiorowski a. Wayss, *B.* 18, 1936).

15. The same replacement is most conveniently effected by means of cuprous bromide (*cf.* reaction 12). A solution of 125 pts. of crystallised  $CuSO_4$  ( $\frac{1}{2}$  mol.), 360 pts. of  $KBr$  (3 mols.), 800 pts. of water, and 110 pts. of conc.  $H_2SO_4$  (1 mol.) is boiled with 200 pts. of copper-turnings till decolourised. The amine (1 mol.) is then added, and into the mixture, heated nearly to boiling, is slowly run a solution of 70 pts.  $NaNO_2$  (1 mol.) in 400 pts. of water (Sandmeyer, *B.* 17, 2650; 18, 1492).

16. By boiling diazo-compounds with aqueous  $HI$  the  $N_2$  group is replaced by  $I$  forming iodo-compounds:  $X.N_2.I = XI + N_2$  (Griess, *B.* 18, 960).

17. By boiling with  $HF$  the  $N_2$  group is replaced by  $F$  giving fluoro-compounds:  $X.N_2.F = XF + N_2$  (Griess, *B.* 18, 960; Paterno a. Oliveri, *G.* 12, 85; 13, 533; Wallach, *A.* 235, 255).

18. By heating diazo-salts with  $Cu_2(ON)$ , the  $N_2$  group is replaced by  $CN$  (*cf.* reactions 12 and 15). The nitriles so formed can be converted into carboxylic acids by saponification, so that by means of this reaction an  $NH_2$  group can be replaced by  $CO_2H$ . 28 pts. of  $KCN$  (96 p.c.) are added to a hot solution of 25 pts. of crystallised  $CuSO_4$  in 150 pts. of water; into this solution, heated to about  $90^\circ$ , is slowly run an aqueous solution of the diazo-chloride. If the nitrile is required for conversion into the acid, it is not always necessary to isolate it, but the crude product of the reaction can be at once saponified (Sandmeyer, *B.* 17, 2650; 18, 1492, 1496).

19. By the action of a warm alcoholic solution of  $K_2S$  the  $N_2$  group is replaced by  $SH$ , thus:  $X.N_2.SH = X.SH + N_2$ . The mercaptans so formed can be converted into sulphonic acids by oxida-

tion with cold  $\text{KMnO}_4$ ; so that by means of this reaction an  $\text{NH}_2$  group can be replaced by  $\text{SO}_2\text{H}$  (Klason, *B.* 20, 349).

20. *Hydric sulphide* converts diazo-benzene into phenyl sulphide  $(\text{C}_6\text{H}_5)_2\text{S}$  (Graebe a. Mann, *B.* 15, 1683).

21. Diazo-compounds combine with *ethyl mercaptan* to form unstable bodies  $\text{X.N}_2.\text{SEt}$ , which when boiled with alcohol yield sulphides:  $\text{X.N}_2.\text{SEt} = \text{X.SEt} + \text{N}_2$  (Stadler, *B.* 17, 2075).

22. By heating with *acetic anhydride*, acetylated phenols are formed:  $\text{X.N}_2.\text{OH} + \text{Ac}_2\text{O} = \text{X.OAc} + \text{N}_2 + \text{AcOH}$  (Wallach, *A.* 235, 234).

23.  $\text{SO}_2$  in presence of boiling alcohol converts some diazo-compounds into the corresponding sulphonic acids:  $\text{X.N}_2.\text{OH} + \text{SO}_2 = \text{X.SO}_3\text{H} + \text{N}_2$  (Hubner, *B.* 10, 1715).

24. *Alkalis* give insoluble pps. of complex constitution (Frankland, *C. J.* 37, 750).

25. Action of *cyanogen compounds* (v. Griess, *B.* 9, 132; 12, 2119; Gabriel, *B.* 12, 1637).

26. *Cuprous nitrite* replaces the diazo-group by  $\text{NO}$ . The amine (1 mol.) is dissolved in exactly 2 mols. of dilute  $\text{HNO}_3$  (or 1 mol. of dilute  $\text{H}_2\text{SO}_4$ ) and the acid solution treated with one half of a solution of 2 mols. of  $\text{NaNO}_2$ , the other half being added when the diazotisation is complete. The solution of the diazo-nitrite is added to a paste of 1 mol. of  $\text{Cu}_2\text{O}$  (obtained by reducing  $\text{CuSO}_4$  with glucose and  $\text{NaOH}$ ) and the decomposition allowed to proceed in the cold. The yield of nitrobenzene from aniline is 42 p.c. of the theoretical, but with other bases it is smaller (Sandmeyer, *B.* 20, 1494).

27. *Primary and secondary amines*, react at once with diazo-compounds forming diazo-amides (q. v.):  $\text{X.N}_2.\text{OH} + \text{H.N.Y} = \text{X.N}_2.\text{NH.Y} + \text{H}_2\text{O}$ . In these bodies the diazo-radicle replaces H united to N, and on treatment with excess of acid they readily regenerate the diazo-compound and amine. When diazo-compounds act upon *salts of aromatic amines*, the diazo-residue may replace H in the carbon-nucleus, with formation of amido-azo-compounds:  $\text{X.N}_2.\text{OH} + \text{H.Y}''.\text{NH}_2 = \text{X.N}_2.\text{Y}''.\text{NH}_2 + \text{H}_2\text{O}$ . In the case of tertiary aromatic amines the latter reaction is the only one possible, but with primary and secondary aromatic amines the replacement in the nucleus may be preceded by the formation of a diazo-amide, when there is no large excess of mineral acid present. The readiness with which amido-azo-compounds are formed varies greatly with the amino: in some cases (e.g.  $\alpha$ - and  $\beta$ -naphthylamine, phenylene diamine, &c.) the replacement in the nucleus appears to take place almost instantly; in others (e.g. aniline) the reaction, at the ordinary temperature, takes several hours for its completion, allowing the intermediate formation of the diazo-amide (Friswell a. Green, *C. J.* 1885, 917; *Proceedings* 1887, 26). In many cases the formation of an amido-azo-compound will take place in presence of a large excess of acid, under which conditions the formation of a diazo-amide is precluded. In the formation of amido-azo-compounds of the benzene series the diazo-residue enters in the para-position to the  $\text{NH}_2$  group; but when this place is already occupied it takes the ortho-position. The ortho-amido-azo-compounds appear to be differently constituted to the para-amido-azo-compounds (v. Azo-compounds). If the amine

does not contain any free para- or ortho-position the formation from it of an amido-azo-compound does not appear to be possible. When a diamine contains displaceable H atoms para to each  $\text{NH}_2$  group, it is capable of reacting with 2 mols. of a diazo-compound to form a disazo-compound:

28. Diazo-compounds readily react upon *phenols* and their sulphonic and carboxylic acids in alkaline solution, forming oxy-azo-compounds  $\text{X.N}_2.\text{OH} + \text{H.Y}''.\text{OH} = \text{X.N}_2.\text{Y}''.\text{OH} + \text{H}_2\text{O}$ . Compounds of the form  $\text{X.N}_2.\text{OY}'$  analogous to the diazo-amides have never been obtained. The above remarks (*reaction* 24) with regard to the position taken by the diazo-group in the benzene-nucleus apply equally to oxy- and to amido-azo-compounds. Also, the di-oxy-compounds, similarly to diamines, can give rise to disazo-compounds  $(\text{X.N}_2).\text{Y}''(\text{OH})_2$  when they contain displaceable H atoms para to each OH group.

29. Diazo-compounds readily react with *pyrrol*, with formation of azo- and disazo-bodies  $\text{X.N}_2.\text{C}_4\text{H}_7\text{NH}$  and  $(\text{X.N}_2)_2\text{C}_4\text{H}_7\text{NH}$ , but no compounds analogous to diazo-amides (O. Fischer a. Hepp, *B.* 19, 2251).

30. *Piperidine*, on the other hand, gives rise to piperidides  $\text{X.N}_2.\text{NC}_5\text{H}_{11}$  (O. Wallach, *A.* 235, 233).

31. *Amido-thiophene*, unlike aniline, does not appear to form diazo-amides when treated with diazo-compounds, but gives at once amido-azo-compounds  $\text{X.N}_2.\text{C}_4\text{SH}_4\text{NH}_2$  (Stadler, *B.* 18, 2318). This is no doubt due to the tendency to replacement of the hydrogen being greater in the thiophene ring than in the benzene ring.

32. Diazo-compounds react with those bodies of the fatty series which contain H united to C, replaceable by sodium, e.g. nitro-methane, nitro-ethane, malonic ether, aceto-acetic ether, other ketonic ethers, &c. The products are mixed azo-compounds: those from nitro-methane, for instance, have the constitution  $\text{X.N}_2.\text{CH}_2(\text{NO}_2)$  (Meyer, *B.* 8, 751, 1073; 9, 381; Zabin, *B.* 11, 1117; Kuppeler, *B.* 12, 2286; Richter a. Münzer, *B.* 17, 1926; Griess, *B.* 18, 961; Bamberger, *B.* 17, 2415; 18, 2563).

**Salts.**—The diazo-salts have the general formula  $\text{X.N}_2.\text{A}$ . They are mostly white crystalline solids, very easily soluble in water, but sparingly in alcohol and ether. They are usually very unstable, and in the dry state are often very explosive, especially the nitrates and picrates. By the action of  $\text{K}_2\text{SO}_4$  upon diazo-chlorides, sulphites are formed of the constitution  $\text{X.N}_2.\text{SO}_3\text{K}$ . Stannic and cuprous salts give double compounds of the formula  $(\text{X.N}_2.\text{Cl})_2\text{SnCl}_4$ ,  $(\text{X.N}_2.\text{Cl})_2\text{CuCl}_2$ ,  $(\text{X.N}_2.\text{Br})_2\text{CuBr}_2$ , &c. (Griess, *B.* 18, 965; Lehmann, *B.* 19, 810). The platino-chlorides  $(\text{X.N}_2.\text{Cl})_2\text{PtCl}_2$  are sparingly soluble pps. An excess of bromine produces yellow or red pps. of the per-bromides  $\text{X.N}_2.\text{Br}_2$ . The diazo-sulphonic and carboxylic acids form salts  $\text{X}''(\text{SO}_3\text{M})_2.\text{N}_2.\text{OH}$  with bases, as well as  $\text{X}''(\text{SO}_3\text{H})_2.\text{N}_2.\text{A}$  with acids.

**Amides.** As already mentioned (*reaction* 27), the action of primary and secondary amines upon diazo-compounds gives rise to diazo-amides of the general formula  $\text{X.N}_2.\text{NH.Y}$ , or  $\text{X.N}_2.\text{N.Y.Y}$ . Thus diazo-benzene and aniline

**Diazo-benzene-anilide (diazoamidobenzene):**  $\text{H}_2\text{N}_2\text{OH} + \text{C}_6\text{H}_5\text{NH}_2 = \text{C}_6\text{H}_5\text{N}_2\text{NH.C}_6\text{H}_5$ . These bodies are in general yellow crystalline solids, stable below  $100^\circ$  when free from acid. Treatment with an excess of mineral acid are resolved, even in the cold, into the diazo-salt and amine. When the amine is aniline, the resolution products again slowly combine, if the conditions are favourable, to give an amido-azo-compound  $\text{X.N}_2\text{Y.NH}$ , identical with the original diazo-amide. The resolution and recombination take place constantly when the diazo-amide is treated with a solution of cold dilute  $\text{HCl}$ , or with unstable salts, such as  $\text{ZnCl}_2$ ,  $\text{CaCl}_2$ , aniline chloride, &c., in alcoholic or aniline solution (Friswell a. Green, *C. J.* 1885, 917; Wallach, *A.* 235, 233). When a diazo-amide is treated with a salt of a base different from that of which it is a compound, the diazo-salt generated will react upon the base of the two whose nuclear hydrogen is not readily replaced. Thus diazo-benzene-diethyl-amide  $\text{C}_6\text{H}_5\text{N}_2\text{NMe}_2$ , treated with aniline hydrochloride gives amido-azo-benzene and diethyl-amine; similarly, diazobenzene-anilide  $\text{C}_6\text{H}_5\text{N.NHC}_6\text{H}_5$ , treated with *m*-phenylene-amine hydrochloride yields di-amido-azo-benzene  $\text{C}_6\text{H}_4\text{N}_2\text{C}_6\text{H}_4(\text{NH}_2)_2$ , whilst aniline is set free; but diazo-benzene-anilide treated with *p*-toluidine hydrochloride gives amido-azo-benzene and *p*-toluidine, because the para H of aniline is more readily replaced than the ortho H of the *p*-toluidine. Even very weak acids, such as acetic acid and phenols, are capable of resolving most diazo-amides. In the latter case the diazo-compounds produced immediately combine with the phenol to form oxy-azo-compounds, for diazo-residues replace the hydrogen of the nucleus more readily in phenols than in amines (Heumann a. Oeconomides, *B.* 20, 201).

In general it may be said that the reactions of the diazo-amides towards reagents in presence of acids, are simply the reactions of the free diazo-salts; thus  $\text{SnCl}_2$  and  $\text{HCl}$  reduce them to hydrazines (*cf.* reaction 7); heating with strong halogen acids gives halo-derivatives of the hydrocarbons (*cf.* reactions 11, 14, 16, and 17); &c.

It appears to be proved (Griess, *B.* 7, 1619; Nöling a. Binder, *Bl.* 42, 336; Meldola a. Streatfeild, *C. J.* 1887, 102, 434) that the diazo-amides of the types  $\text{X.N}_2\text{NH.Y}$  and  $\text{Y.N}_2\text{NH.X}$  are identical—that is, the same body is obtained whichever of the two amines is diazotised and combined with the other. The resolution of these unsymmetrical diazo-amides quite corresponds to their formation, for they yield a mixture of both diazo-compounds  $\text{X.N}_2\text{OH}$  and  $\text{Y.N}_2\text{OH}$ , and both amines  $\text{X.NH}_2$  and  $\text{Y.NH}_2$ . For instance, the compound  $\text{C}_6\text{H}_5\text{N}_2\text{H.C}_6\text{H}_4$  is obtained by combining either diazo-benzene with *p*-toluidine, or *p*-diazo-toluene with aniline; and on treatment with  $\text{HCl}$  it splits up equally into diazo-benzene, *p*-diazo-toluene, aniline, and *p*-toluidine. When only 1 mol. of  $\text{HCl}$  is present these resolution products will recombine to form one or more amido-azo-compounds according to circumstances.

Alkalis, even in boiling aqueous or alcoholic solution, usually have no action upon diazo-

amides. The H of the NH group of the primary diazo-amides appears to have slightly acid properties, and by introduction of  $\text{NO}_2$  groups into the nuclei the diazo-amide becomes sufficiently acid to dissolve in aqueous alkalis and form tolerably stable salts  $\text{X''(NO}_2\text{).N}_2\text{NH.Y(NO}_2\text{)}$  (Meldola a. Streatfeild, *C. J.* 1886, 621; 1887, 102, 434).

By the action of alkyl haloids upon the primary diazo-amides dissolved in an alcoholic solution of (1 mol. of) sodium ethylate secondary diazo-amides are obtained (M. a. S.; Friswell a. Green, *B.* 19, 2034; *C. J.* 1886, 746). When the two aromatic nuclei are the same the secondary diazo-amides obtained by alkylation are identical with those got by direct combination of the diazo-compounds with secondary amines. But according to Meldola and Streatfeild (*C. J.* 1887, 434) the compound obtained by ethylating the unsymmetrical *m*-nitro-diazo-benzene-*p*-nitranilide [3:1]  $\text{C}_6\text{H}_4(\text{NO}_2)\text{N}_2\text{H.C}_6\text{H}_4(\text{NO}_2)$  [1:1] (which is obtained either from *m*-nitro-diazo-benzene and *p*-nitraniline, or from *p*-nitro-diazo-benzene and *m*-nitraniline) is different from either of the two ethyl-derivatives

[3:1]  $\text{C}_6\text{H}_4(\text{NO}_2)\text{N}_2\text{H.NEt.C}_6\text{H}_4(\text{NO}_2)$  [1:1] and [4:1]  $\text{C}_6\text{H}_4(\text{NO}_2)\text{N}_2\text{H.NEt.C}_6\text{H}_4(\text{NO}_2)$  [1:3], obtained by combining *m*- and *p*-nitro-diazo-benzene with ethyl-*p*- and *m*-nitranilines respectively. The two latter ethyl derivatives are split up by acids into *m*-nitro-diazo-benzene and ethyl-*p*-nitraniline, and *p*-nitro-diazo-benzene and ethyl-*m*-nitraniline respectively; but the former ethyl derivative (obtained by ethylation) yields both diazo-compounds and both ethyl-nitranilines in about equal amounts.

**Constitution of diazo-amides.**—Although a considerable amount of work has been done on this subject, the matter is still far from settled. The formula  $\text{X.N=N.Y}$  is disproved by the

$$\begin{array}{c} \text{N} \\ \diagup \quad \diagdown \\ \text{X} \quad \text{N} \quad \text{Y} \end{array}$$

resolution of the alkyl derivatives into diazo-compound and alkylated amine, since the latter could not be obtained from a compound of that structure (Friswell a. Green, *C. J.* 1886, 746, and *B.* 19, 2034). The formula  $\text{X.N.NH.Y}$  does not

$$\begin{array}{c} \text{N} \\ | \\ \text{X.N.NH.Y} \end{array}$$

appear to have much probability, since one would expect a body of the constitution  $\text{C}_6\text{H}_5\text{N}_2\text{N.NHC}_6\text{H}_5$  to give on reduction  $\text{NH}_2$  and hydrazobenzene; these bodies, however, are not formed from diazo-benzene-anilide, even by adding sodium to its boiling alcoholic solution (F. a. G.). Neither the latter formula nor that usually assumed  $\text{X.N:N.NH.Y}$  is capable of explaining the existence of more than two isomeric alkyl derivatives.

For further references concerning the diazo-amides see Bayer a. Jäger, *B.* 8, 148, 893; Sarauw, *B.* 14, 2142; 15, 42; Nöling a. Baumann, *B.* 18, 1147; Stadel a. Bauer, *B.* 19, 1952; Wallach, *A.* 235, 233; Berntsen a. Goske, *B.* 20, 926.

**Imides.**—Obtained by the action of  $\text{NH}_3$  upon the per-bromides:

the decomposition of nitroso-hydrazines:

They are usually yellowish oily liquids, insoluble in water, exploding when heated. When heated with conc. HCl they are converted into chloro-amido-compounds:  $HX.N_2 + HCl \rightarrow X.Cl(NH_2) + N_2$ . Diazo-benzene-imide heated with  $H_2SO_4$  diluted with an equal volume of water is converted into *p*-amido-phenol:  $C_6H_5.N_2 + H_2O \rightarrow C_6H_4(OH)NH_2 + N_2$  (Griess, B. 19, 313; Fischer, A. 190, 67; 232, 236; Silberstein, J. pr. (2) 27, 116). Diazo-benzoic acid reacts with phenyl-hydrazine, forming the imides of diazo-benzoic acid and of diazo-benzene together with amido-benzoic acid and ani-

$C_6H_4(NH_2)CO_2H + C_6H_5.NH_2$ . This equation is general (Griess, B. 20, 1529).

**Diazo-compounds derived from o-amido-azo-compounds.**—Although the so-called o-amido-azo-compounds probably do not contain an  $NH_2$  group, but are hydrazimido-

they are, nevertheless, slowly attacked by nitrous acid, with production of diazo-compounds. The only member of this class of diazo-compounds at present examined is that obtained by diazotising o-amido-azo-toluene. In some of its reactions it behaves like an ordinary diazo-compound, in others quite differently. On heating with water or alcohol it is decomposed with evolution of nitrogen. By zinc-dust and alcohol it is converted into *m*-p-azotoluene and  $N_2$ . It is not reduced by  $SnCl_2$  or  $SO_2$  to a hydrazine, but gives a stable compound  $C_6H_4.N_2$ , which probably has the constitution

converted by bromine into the per-bromide of the original diazo-compound. The diazo-imide loses nitrogen on heating, and yields tolyl-

identical with that obtained by oxidation of o-amido-azo-toluene (tolyl-hydrazimido-toluene). Hence the constitution of this peculiar diazo-compound is probably

**B. Fatty diazo-compounds**  $X'' \begin{array}{c} \text{N} \\ \diagup \\ \text{N} \end{array}$  As

already stated, the fatty diazo-compounds contain a molecule of water less than the aromatic diazo-hydrates. Their discovery is quite recent, and is due to Curtius. At present only a few members of the group are known; these are obtained by the action of  $NaNO_2$  upon the hydrochlorides of amido-fatty-ethers  $X''H.CO_2R$ ,

and hence have the constitution  $X''(N)CO_2R$ . They are unstable oily bodies, which exhibit the following reactions:—1. By boiling with water or dilute acids, they are usually converted into oxy-ethers, e.g.  $CH_2(OH)CO_2Et$ , with evolution of nitrogen; however, diazo-

$C(N_2)CO_2Et$  succinic ether | by this treatment gives fumaric ether.—2. With alcohols they yield alkyl-oxy-ethers, e.g.  $CH_2(OEt)CO_2Et$ .—3. With organic acids they yield alkoyl-oxy-ethers, e.g.  $CH_2(OAc)CO_2Et$ .—4. With aldehydes they yield alkoyl-ethers, e.g.  $CH_2Ac.CO_2Et$ .—5. With zinc-dust and acetic acid, they are reduced first to hydrazines, and then to the original amido-ethers.—6. In etheral solution converts them into di-iodo-ethers, e.g.  $CH_2I.CO_2Et$ ; bromine and chlorine act similarly.—7. By long boiling with aromatic hydrocarbons, nitrogen is evolved, and condensation-products are formed.—8. By treatment with conc. halogen acids they yield haloid ethers, e.g.  $CH_2Cl.CO_2Et$ .—9. By treatment of the diazo-ethers with  $NH_3$  they are converted into the corresponding amides, e.g.  $CH(N_2)CO.NH_2$ , whose reactions are similar to those of the ethers. The free diazo-acids, e.g.  $CH(N_2)CO_2H$ , and their salts, have not yet been isolated, on account of their instability (Curtius, B. 17, 953; B. 18, 1283; Buehner a. Curtius, B. 18, 2371; 19, 850; Curtius a. Koch, B. 18, 1293; 19, 2160).

#### DESCRIPTION OF DIAZO-COMPOUNDS.

A large number of diazo-compounds are mentioned under the amido-compounds from which they are formed.

**Pseudo-diazo-acetamide**  $C_2H_5N_3O_2$ . Formed, together with diazoacetamide, by prolonged action of strong aqueous  $NH_3$  in the cold upon the methyl ether of diazoacetic acid  $CHN_2.CO_2Me$  (Curtius, B. 18, 1287). Fine crystalline yellow powder, consisting of microscopic quadrate plates. Sl. sol. cold water, dilute HCl, and acetic acid. Insol. alcohol, ether, and benzene. Dibasic acid. On warming with water it evolves nitrogen. Aqueous alkalis evolve nitrogen and ammonia. It gives a green colouration with Fehling's solution; on boiling a black pp. is formed. Silver and mercury salts are reduced on boiling.

**Salts.**— $A''(NH_4)_2$ : small yellow tables; sl. sol. cold water [c. 155°].— $A''Ag_2$  1½ aq: yellow microcrystalline pp., v. sl. sol. water. Explodes on heating.— $A''Hg$ : yellow pp.— $A''Cu^+$ : sparingly soluble reddish-brown pp.— $A''Pb$ : yellow pp.

**Diazo-acetic acid**  $CHN_2.CO_2H$ . The free acid and its salts have not been isolated on account of their instability. The alkaline salts are obtained in solution by treating the methyl ether with cold aqueous alkalis.

**Methyl ether**  $MeA'$ . (129°) at 721 mm. S.G. <sup>21</sup> 1.139.

**Ethyl ether**  $EtA'$ . [–24°]. (144°) at 721 mm. S.G. <sup>21</sup> 1.073. Formed by the action of  $NaNO_2$  on a concentrated solution of the hydrochloride of amido-acetic ether. Yellow oil. V. sl. sol. water; miscible with alcohol, ether, benzene, and light petroleum. Explodes when conc.

$\text{H}_2\text{SO}_4$  is poured upon it. **Reactions.**—1. Boiling water gives glycollic ether, nitrogen, and alcohol. —2. Boiling alcohol gives  $\text{CH}_3(\text{OEt})_2\text{CO}_2\text{Et}$  and nitrogen. —3. Benzoic acid gives rise to  $(\text{H}_2(\text{OBz}))_2\text{CO}_2\text{Et}$ . —4. Reduces  $\text{AgNO}_3$  in cold aqueous solution. —5. Reduces hot Fehling's solution. —6. Zinc-dust and acetic acid form an instable hydrazo-derivative  $\text{NH}_2\text{NHCH}_2\text{CO}_2\text{Et}$ , which is further reduced to ammonia and  $\text{NH}_2\text{CH}_2\text{CO}_2\text{Et}$ . The hydrazo-derivative reduces cold Fehling's solution. —7. Combines with aldehydes, thus:  $\text{Ph}\cdot\text{CHO} + \text{CHN}_2\text{CO}_2\text{Et} \rightarrow \text{Ph}\cdot\text{CO}\cdot\text{CH}_2\text{CO}_2\text{Et} + \text{N}_2$ . —8. Changes on standing into azin-succinic ether,  $\text{C}_6\text{H}_4\text{N}_2\text{O}_2\text{Et}$ , [245°]. —9. Boiling aniline produces  $\text{NPh}\cdot\text{H}\cdot\text{CH}_2\text{CO}_2\text{Et}$ . —10. Conc.  $\text{HCl}$  gives  $\text{CH}_2\text{Cl}\cdot\text{CO}_2\text{Et}$ . —11. Hot conc.  $\text{KOH}$  forms a crystalline pseudo-diazo-salt whence boiling dilute  $\text{H}_2\text{SO}_4$  liberates hydrazine,  $\text{N}_2\text{H}_4$  (Curtius, *B.* 20, 1632). —12. Boiling aromatic hydrocarbons produce condensation products; thus benzene gives  $\text{C}_6\text{H}_5\text{CO}_2\text{Et}$  (Buchner & Curtius, *B.* 18, 2371).

**Iso-anylether**  $\text{C}_6\text{H}_5\text{A}'$ , (160°) at 720 mm. **Amide**  $\text{CHN}_2\text{CONH}_2$  [114°]; yellow tables or prisms; v. sol. cold water or alcohol. Formed by the action of strong aqueous  $\text{NH}_3$  upon the methyl-ether. The aqueous solution decomposes on boiling with evolution of nitrogen and formation of glycolamide. By treatment in alcoholic solution with iodine it is converted into di-iodo-acetamide  $\text{CHI}_2\text{CONH}_2$  with evolution of nitrogen. It gives a blood-red colouration with  $\text{AgNO}_3$ , and in a few moments a reduction to metallic silver. It also reduces  $\text{Hg}(\text{NO}_3)_2$  and  $\text{Cu}(\text{OAc})_2$ . With Fehling's solution it produces a red colouration, which becomes green on boiling (Curtius, *B.* 17, 953; 18, 1233).

#### Diazo-amido-benzoic acid

$\text{C}_6\text{H}_3(\text{NH}_2)\text{CO}_2\text{O} \begin{smallmatrix} (1) \\ \diagup \\ \text{N}:\text{N} (6) \end{smallmatrix}$ . Obtained by adding sodium nitrite to a solution of (6:3:1)-*p*-di-amido-benzoic acid containing barely sufficient  $\text{HCl}$  to dissolve it. Long slender needles, or four-sided plates. Yellow colour. Bitter taste. V. sol. hot water, sl. sol. hot alcohol, insol. ether. Has no acid properties, but is a weak base. When dry it explodes on heating. It is decomposed by long boiling with water. It combines with amines and phenols to form azo-compounds.

**Salts.**— $\text{B}\cdot\text{HCl}$ : white six-sided plates. —  $\text{B}\cdot\text{H}_2\text{Cl}_2\text{P}\cdot\text{Cl}$ : sparingly soluble small yellow trimetric plates. —  $\text{B}\cdot\text{AuCl}_4\cdot\text{HCl}$ : yellow insoluble needles (Griess, *B.* 17, 603).

***p*-Diazo-aniline salts** are formed by diazotising salts of *p*-phenylene-diamine (Griess, *B.* 17, 607). —  $\text{C}_6\text{H}_3(\text{NH}_2)_2\text{N}_2\text{ClHClAu}_2\text{Cl}_6$  is an insoluble pp.

***m*-Diazo-aniline imide**  $\text{C}_6\text{H}_3(\text{NH}_2)\text{N} \begin{smallmatrix} \diagup \text{N} \\ \parallel \\ \diagdown \text{N} \end{smallmatrix}$ .

***m*-Amido-diazo-benzene imide.** Yellowish oil. Volatile with steam. Easily soluble in alcohol and ether.

**Preparation.**—*m*-Amido-phenyl-oxamic acid  $\text{C}_6\text{H}_3(\text{NH}_2)\text{NH}\cdot\text{C}_2\text{O}_2\cdot\text{OH}$  is diazotised and converted into the tribromide  $\text{C}_6\text{H}_3(\text{N}\cdot\text{Br})_2\text{NH}\cdot\text{C}_2\text{O}_2\cdot\text{OH}$ . By treatment with  $\text{NH}_3$  this yields the imide  $\text{C}_6\text{H}_3(\text{N}_2)\text{NH}\cdot\text{C}_2\text{O}_2\cdot\text{OH}$ , which on boiling with aqueous  $\text{KOH}$  splits off the oxalyl group with

production of *m*-diazo-aniline imide. On diazotisation it gives a diazo-compound which combines with phenols and amines to form azo-dyestuffs. Decomposes explosively on heating.

**Salts.**— $\text{B}\cdot\text{HCl}$ : white soluble trimetric plates. —  $\text{B}\cdot\text{H}_2\text{Cl}_2\text{P}\cdot\text{Cl}$ : yellow needles (Griess, *B.* 18, 963).

#### *m*-Diazo-aniline piperidine.

##### Acetyl derivative

$\text{C}_6\text{H}_3(\text{NHAc})\text{N}_2\cdot\text{NC}_2\text{H}_5$ , [101°]. From acetyl-*m*-tolylene-diamine hydrochloride by diazotisation and treatment with piperidine (Wallach, *A.* 235, 266).

##### (a)-Diazo-anthraquinone nitrate

$\text{C}_{14}\text{H}_9\text{O}_2\text{N}_2\text{NO}_3$ . Formed by passing nitrous acid gas into a solution of (a)-amido-anthraquinone in dry ether (Böttger & Petersen, *A.* 166, 150). Powder, m. sol. water, v. sol. alcohol, insol. ether. When heated with water it gives  $\text{N}_2$  and *m*-oxy-anthraquinone.

**Diazo-benzene.** *References:* Griess, *Tr.* 1864, iii, 667; *A.* 113, 201; 137, 39.

**Hydroxide**  $\text{Ph}\cdot\text{N}_2\cdot\text{OH} (?)$ . On adding acetic acid to an aqueous solution of  $\text{Ph}\cdot\text{N}_2\cdot\text{OK}$  a thick yellow oil is pptd.; this may be diazo-benzene hydroxide. It is very unstable.

**Salts.**— $\text{Ph}\cdot\text{N}_2\cdot\text{OK}$ . A crystalline substance obtained by adding excess of conc. aqueous  $\text{KOH}$  to a saturated solution of diazo-benzene nitrate, and evaporating at 100°. Detonates feebly at 130°. V. sol. water and alcohol, insol. ether. —  $\text{Ph}\cdot\text{N}_2\cdot\text{OAg}$ : obtained as a greyish-white pp. on adding  $\text{AgNO}_3$  to an aqueous solution of the preceding; explodes when heated. —  $(\text{Ph}\cdot\text{N}_2\cdot\text{O})_2\text{Hg}$ : white pp. got by adding  $\text{HgCl}_2$  to the potassium salt (Griess, *A.* 137, 57).

**Nitrate.** —  $\text{Ph}\cdot\text{N}_2\cdot\text{NO}_3$ . S.G. 1.37. H.F. — 47,400 (Berthelot & Vieille, *C. R.* 92, 1074). Prepared by passing nitrous fumes at 0° into an aqueous solution of aniline nitrate containing undissolved aniline nitrate in suspension; pptd. by adding alcohol and ether. Needles; v. e. sol. water, m. sol. alcohol, insol. ether and benzene. Stable in dry air in the dark, but decomposed in moist air. Explodes at 90° forming  $\text{CO}$ ,  $\text{CH}_4$ ,  $\text{N}$ ,  $\text{HCN}$ ,  $\text{CH}_3$ , and  $\text{C}$ . The decomposition may be roughly represented thus:  $\text{C}_6\text{H}_5\text{N}_2\cdot\text{NO}_3 = 3\text{CO} + 3\text{C} + 5\text{H} + 3\text{N}$ .

**Reactions.**—1. Barium carbonate added to its aqueous solution produces  $\text{Ph}\cdot\text{N}_2\cdot\text{C}_6\text{H}_4\cdot\text{OH}$  and  $\text{C}_{10}\text{H}_7\text{N}_2\text{O}$  [131°]. This 'benzene-di-azo-phenol' is perhaps  $\text{C}_6\text{H}_5\text{N}_2\cdot\text{C}_6\text{H}_4(\text{OH})\cdot\text{N}_2\cdot\text{C}_6\text{H}_5$  for it may be reduced by  $\text{HI}$  to di-amido-phenol (P. F. Frankland, *C. J.* 37, 751). It is soluble in  $\text{NaOH}$  aq. —2. Aqueous  $\text{NaOH}$ , added to neutralisation, gives the 'benzene-di-azo-phenol' and a brown substance,  $\text{C}_{20}\text{H}_{12}\text{N}_4\text{O}$ , insol.  $\text{NaOH}$  aq. —3. Aqueous ammonia produces diazo-benzene-anilide and two amorphous brown substances,  $\text{C}_{10}\text{H}_7\text{N}_2\text{O}$  and  $\text{C}_{10}\text{H}_7\text{N}_2\text{O}$ . The latter is very explosive and is decomposed by boiling  $\text{HCl}$  into phenol, aniline, and  $\text{N}_2$ . —4. Boiling dilute  $\text{HNO}_3$  (1 mol.) forms *o*- and *p*-nitro-phenol (Nöling & Wild, *B.* 18, 1338). —5. Aqueous  $\text{KFeCy}_3$  forms a compound  $\text{C}_6\text{H}_5\text{N}_2$ , [150°] (Griess, *B.* 9, 132). —6. Potassic ferricyanide gives  $(\text{C}_6\text{H}_5\text{N}_2)_2(\text{HFeCy}_6)_2$ . —7. Sodium nitroprusside gives the compound  $\text{C}_6\text{H}_5\text{N}_2\cdot\text{HFeCy}_3(\text{NO})$  aq (Griess, *B.* 12, 2120). —8. Nitro-benzyl cyanide and alcoholic  $\text{KOH}$  give a pp. of  $\text{C}_6\text{H}_5\text{N}_2\text{O}_2$  [202°] (Perkin, *C. J.* 43, 111).

**Chloride.**— $\text{Ph}\cdot\text{N}_2\cdot\text{Cl}$ . Formed in solution

by diazotising aniline hydrochloride. *Combinations.*— $(C_6H_5N_2Cl)_2SnCl_2$ ; white plates, sol. water, v. sl. sol. alcohol and ether (Griess, B. 18, 965).— $(PhN_2Cl)_2PtCl_2$ ; yellow prisms, v. sl. sol. water, insol. alcohol and ether.— $PhN_2ClAuCl_2$ ; golden plates, in sol. water, m. sol. warm alcohol.

*Perbromide.*  $PhN_2SO_3H$ . Formed by adding bromine to an ethereal solution of diazo-benzene amide, or by warming the perbromide for a long time with ether. Pearly plates, v. e. sol. water, insol. ether.

*Perbromide.*— $PhN_2Br_2$ . Formed by adding bromine dissolved in  $HClAq$  to an aqueous solution of a diazobenzene salt. Large yellow plates, in ol. water and ether, m. sol. cold alcohol. Gives bromo-benzene when distilled with  $Na_2CO_3$  or when heated with alcohol.

*Sulphate.*  $PhN_2SO_3H$ . Ppd. by adding alcohol (3 vol.) and ether to a solution of diazobenzene nitrate mixed with an equivalent quantity of  $H_2SO_4$ . Prisms, v. e. sol. water, v. sl. sol. alcohol, insol. ether. Explodes at  $100^\circ$ .

*Dicyanide.*  $C_6H_5N_2$  or  $C_6H_5N_2CN.HCN$ . [69]. Formed by the action of a diazo-benzene salt on a solution of KCN. Readily decomposes (Gabriel, B. 12, 1637).

*Picrate.*  $PhN_2O_2C_2H_3(NO)_2$ . Yellow needles, obtained by mixing solutions of diazobenzene nitrate and sodium picrate. Very explosive (Baeyer and Jager, B. 8, 984).

*Sulphate.* The potassium salt,  $C_6H_5N_2SO_3K$ , called also potassium diazobenzene sulphate, is ppd. by adding KOH to a mixture of diazobenzene nitrate and  $K_2SO_4Aq$  (E. Fischer, J. 190, 73). It forms explosive yellow crystals. Bromine in conc.  $HBrAq$  ppd. diazobenzene perbromide. Zinc-dust and acetic acid reduce it to the corresponding hydrazo-compound.

*Nitride.* Converted by  $Cu_2O$  into nitro-benzene (Sandmeyer, B. 20, 1107).

*Benzene-sulphonate.*  $PhN_2SO_3C_6H_5$ , [76]. From sodium benzene sulphinate and diazobenzene nitrate (Königs, B. 10, 1532). Orange fubles (from alcohol); insol. cold water, v. sl. alcohol and ether.

*m-Tetra-azo-benzene*  $C_6H_4(N_2O)_2$ , [13]. Formed by the action of a large excess of nitrous acid upon *m*-phenylene diamine in presence of a large excess of  $HCl$ . It combines with 2 mol. of an amine or phenol.

*Salts.*  $C_6H_4(N_2Cl)_2PtCl_2$ ; small yellow plates; nearly insoluble in cold water and alcohol; heated with dry  $Na_2CO_3$  it yields dichloro-benzene.— $C_6H_4(N_2Cl)_2AuCl_2$ ; pp. of yellow microscopic needles, explosive (Griess, B. 19, 317).

*p-Tetra-azo-benzene*  $C_6H_4(N_2OH)_2$ , [11]. Formed by the action of an excess of nitrous acid upon *p*-phenylene diamine in presence of a large excess of acid.  $C_6H_4(N_2Cl)_2$ ; yellow crystalline explosive ppd. by heating with dry  $Na_2CO_3$ ; it yields 2-dichloro-benzene (Griess, B. 19, 319).

*Diazo-benzene-*m*-amido-benzoic acid*  $C_6H_5N_2NH(C_6H_4CO_2H)$ . Formed by mixing solutions of diazo-benzene nitrate and *m*-amido-benzoic acid (Griess, J. 137, 621). Small yellow plates (from ether). Sl. sol. alcohol, v. e. sol. ether.— $C_6H_5N_2NH(OH)PtCl_2$ .

*Ethyl ether.*  $EtA'$ ; yellow crystals, v. e. sol. alcohol and ether.— $C_6H_5N_2NH(OH)PtCl_2$ .

The above diazo-benzene-amido-benzoic acid  $C_6H_5N_2NH(C_6H_4CO_2H)$  is identical with diazo-benzoic-acid-anilide,  $C_6H_5NH.N_2C_6H_4CO_2H$  (Griess, B. 7, 1619; cf. Meldola, C. J. 51, 435).

*Diazo-benzene-anilide*  $PhN_2NHPh$ . *Diazo-anilidobenzene*. Mol. w. 197. [96].

*Formation.*—By passing nitrous acid gas into an alcoholic solution of aniline (Griess, A. 121, 258).

*Preparation.*—A solution of 18 pts. of sodium nitrite is added to a solution 50 pts. aniline, 15 pts. conc.  $H_2SO_4$  in about 1,500 pts. of water, the temperature of the mixture is kept for 15 mins. between  $25^\circ$  and  $30^\circ$ , the pp. then filtered off, washed, and dried; the yield is 98 p.c. of the theoretical (Stadel a. Bauer, B. 19, 1952).

*Properties.* Golden plates (from alcohol), or large flat prisms (from benzene). Explodes between  $150^\circ$  and  $200^\circ$ . Insol. water, and dilute acids, m. sol. cold alcohol, v. sol. hot alcohol, v. sol. ether and benzene.

*Reactions.* 1. Hot conc.  $HClAq$  splits it up into phenol, nitrogen, and aniline; cold  $HClAq$  gives aniline and diazobenzene chloride, which, if an excess (more than 1 mol.) of  $HCl$  is not present, recombine forming benzene-azo-aniline (q. v.). Unstable chlorides such as aniline hydrochloride or  $ZnCl_2$  also effect the conversion into benzene-azo-aniline.—2. *Bromine* in  $HBrAq$  gives diazobenzene bromide and tri-bromo-aniline.—3. The hydrogen atom of the  $NH$ -group can be readily replaced by alkyl radicals by treatment with alcoholic haloids, and sodium ethylate. The alkylated diazobenzene-anilides thus obtained are split up by acids into diazobenzene and the corresponding mono-alkyl-aniline. A proof is thus afforded of the unsymmetrical structure of the anilide, and since the only other possible formula  $C_6H_5N.NH(C_6H_5)$  is

excluded by the fact that the body is not reduced by alkaline reducing agents to hydrazobenzene and  $NH_3$ , the formula  $PhN_2NHPh$  is probably correct (Friswell a. Green, C. J. 49, 716; B. 19, 2031). 4. *Phenol* at  $100^\circ$  gives benzene-*p*-azo-phenol. Resorcin and the naphthols act similarly (Heumann a. Oeconomidis, B. 20, 372).

*Salts.*  $PhN_2NArPh$ ; orange needles.— $(PhN_2NHPhHCl)_2PtCl_2$ ; unstable crystals.

*Di-sulphonamide*  $C_6H_4(SO_3NH_2)_2NH(C_6H_5SO_3NH_2)$ , [183]. Yellow needles. From  $C_6H_4(SO_3NH_2)_2NH_2$ ,  $HNO_3$ , and nitrous acid gas (Hybbeneth, J. 221, 206). Conc.  $HCl$  converts it into  $C_6H_4ClSO_2NH_2$ ,  $C_6H_4(NH)SO_2NH_2$  and  $N_2$ .

*Diazo-benzene-azo-benzene-*p*-sulphonic acid*  $C_6H_4(SO_3-N_2)-C_6H_4-N_2$ . Small yellow needles.

Nearly insoluble in most solvents. Formed by long action of nitrous acid on amido-benzene-azo-benzene-sulphonic acid. Boiled with water it gives oxy-benzene-azo-benzene-sulphonic acid; with alcohol it gives benzene-azo-benzene-sulphonic acid (Griess, B. 15, 2196).

*Diazo-benzene-benzyl-anilide*  $C_6H_5N_2N(C_6H_5)C_6H_5$ . *Benzyl-diazo-amido-benzene*, [81]. Yellow needles. V. sol. acetone, m. sol. alcohol, insol. water.

*Preparation.*—30 g. of sodium are dissolved

in 800 c.c. of alcohol, a hot solution of 200 g. of diazo-benzene-anilide in 500 c.c. of absol. alcohol added, and the mixture heated with 140 g. of benzyl chloride for 1 or 2 hours; the product is precipitated by water and recrystallised from alcohol; yield, 200 g.

**Reactions.**—On heating it decomposes explosively. By excess of HCl it is resolved into diazobenzene and benzyl-aniline (Friswell a. Green, *B.* 19, 2036).

**Diazo-benzene-bromo-anilide** *r.* **DIAZO-BROMO-BENZENE-ANILIDE.**

**Diazo-benzene-*p*-chloro-anilide.** Formed from *p*-chloro-diazo-benzene and aniline. By warming with phenol it gives oxy-azo-benzene and *p*-chloraniline (Heumann a. Oeconomidis, *B.* 20, 908).

**Diazo-benzene-ethylamide**  $\text{Ph.N}_2\text{NH.Et}$ . From diazo-benzene nitrate and ethylamine. Picrate  $\text{C}_{11}\text{H}_{11}\text{N}_3\text{O}_5$  (NO<sub>2</sub>)<sub>2</sub>OH.

**Diazo-benzene-ethyl-hydrazide**  $\text{Ph.N}_2\text{N}_2\text{H.Et}$ . From diazo-benzene nitrate and ethyl hydrazine (E. Fischer, *A.* 190, 306). Very unstable oil. Reduced in alcoholic solution by zinc dust and acetic acid to ethyl-hydrazine and phenyl-hydrazine.

**Diazo-benzene-imide**  $\text{C}_6\text{H}_5\text{N}_2$ . *Tri-azo-benzene.*

**Formation.** 1. Diazobenzene perbromide is treated with aqueous NH<sub>3</sub> and the product distilled with steam, dried over CaCl<sub>2</sub> and rectified under diminished pressure (Griess, *Tr.* 1861, iii, 700). 2. By warming nitroso-phenyl-hydrazine with dilute KOH (Fischer, *A.* 190, 92).—3. By adding Na<sub>2</sub>CO<sub>3</sub> to a mixture of diazo-benzene sulphate and hydroxylamine.

**Properties.**—A heavy oil; insol. water, m. sol. alcohol and ether. Detonates when distilled under atmospheric pressure. Not attacked by KOH.

**Reactions.**—1. Reduced in alcoholic solution by Zn and H<sub>2</sub>SO<sub>4</sub> to aniline and NH<sub>3</sub>. 2. By heating with strong HCl it is converted into a mixture of *o* and *p*-chloro-aniline:

3. By heating with H<sub>2</sub>SO<sub>4</sub> diluted with an equal volume of water it is converted into *p*-amido-phenol:  $\text{C}_6\text{H}_5\text{N}_2 + \text{H}_2\text{O} = \text{C}_6\text{H}_4\text{NH}_2 \cdot \text{O} + \text{N}_2 = \text{C}_6\text{H}_4(\text{OH})\text{NH}_2 + \text{N}_2$  (Griess, *B.* 19, 313).

**Diazo-benzene-dimethylamide**  $\text{Ph.N}_2\text{NMe}_2$ . From diazobenzene nitrate and aqueous dimethylamine (Baeyer a. Jäger, *B.* 8, 893). Yellowish oil; explodes when large quantities are heated; volatile with steam; insol. water and alkalis, v. c. sol. alcohol, ether, and acids. Decomposed by acids into diazobenzene salts and dimethylamine. Aniline hydrochloride forms diazo-benzene-anilide and NMe<sub>2</sub>H hydrochloride. Picrate  $\text{Ph.N}_2\text{NMe}_2\text{C}_6\text{H}_4(\text{NO}_2)_2(\text{OH})$ ; yellow needles.

**Diazo-benzene-methyl-anilide**  $\text{C}_6\text{H}_5\text{N}_2\text{NMe.C}_6\text{H}_5$ . *Methyl-diazo-amido-benzene.* Heavy deep-yellow oil. Not volatile with steam. Miscible with alcohol, insol. water.

**Preparation.**—30 g. of sodium are dissolved in 800 c.c. of absolute alcohol and mixed with a hot solution of 200 g. diazobenzene-anilide in 500 c.c. of absolute alcohol; when nearly cold 170 g. of methyl iodide are added; a vigorous reaction soon sets in and is completed by 1 or 2

hours' cobobation; half the alcohol is then distilled off and the residue precipitated by water, the oil separated and dried over CaCl<sub>2</sub>; the yield is 200 grms.

**Reactions.**—On heating it decomposes explosively. By excess of HCl it is resolved into diazobenzene chloride and methylaniline (Friswell a. Green, *C. J.* 49, 718; *B.* 19, 2035).

**Diazo-benzene phosphonic acid nitrate** (?).  $\text{NO}_2\text{N}_2\text{C}_6\text{H}_4\text{PO(OH)3aq}$  [188]. S. 58 at 18°; 59 at 80°. Formed by passing nitrous acid gas into a boiling solution of amido-benzene phosphonic acid in HNO<sub>3</sub>Aq (Miehl dis a. Benzinger, *A.* 188, 288). Long white prisms (from HNO<sub>3</sub>Aq). Explodes above 190°. V. sol. alcohol, sl. sol. ether. Not affected by boiling water, even in presence of H<sub>2</sub>SO<sub>4</sub>; slightly decomposed by boiling NaOH(Aq).

**Salts.**—NaA" 2aq. KA" aq.—BaA" 3aq.—AgA"—PbA".

**Diazo-benzene-piperidine**  $\text{Ph.N}_2\text{NC}_4\text{H}_8$  [43] (Baeyer a. Jäger, *B.* 8, 893; Wallach, *A.* 235, 241).

**Preparation.**—Aniline (100g.) is dissolved in aqueous HCl (210 c.c.) and the solution at 0° is diazotised with NaNO<sub>2</sub> (74 p.) and then poured into a dilute aqueous solution of piperidine (100 g.) containing KOH (60 g.) cooled with ice.

**Properties.**—Crystals (from ether or petroleum-ether).

**Reactions.**—1. HCl passed into an ethereal solution gives diazobenzene chloride and piperidine hydrochloride. Aqueous HCl acts similarly. 2. Warm HCl forms N<sub>2</sub> chlorobenzene and piperidine hydrochloride; phenol is a by-product. HBr and HI act similarly.—3. Hot dilute H<sub>2</sub>SO<sub>4</sub> forms phenol. 4. An ethereal solution of picric acid gives diazo benzene picrate.

#### *o*-Diazo-benzene sulphonic acid

$\text{C}_6\text{H}_4\text{SO}_3\text{N}_2$  Yellowish tables, obtained by passing nitrous acid gas into water containing *o*-amido-benzene sulphonic acid in suspension (Bernsen a. Limprieth, *A.* 177, 101).

#### *m*-Diazo-benzene sulphonic acid

$\text{C}_6\text{H}_4\text{SO}_3\text{N}_2$ . Prepared by passing nitrous acid gas into a concentrated solution of *m*-amido-benzene sulphonic acid, containing the free acid in suspension (Meyer a. Stuber, *A.* 165, 165; Bernsen, *A.* 177, 88). Small columns (from water). Very explosive when dry. V. sol. water and decomposed by it at 60°. Boiling HBr gives *m*-bromo-benzene sulphonic acid. Boiling alcohol has no action.

***m*-DIAZO-BENZENE SULPHONIDE NITRATE**  $\text{NO}_2\text{N}_2\text{C}_6\text{H}_4\text{SO}_3\text{NH}_2$ . From  $\text{C}_6\text{H}_4(\text{NH}_2)\text{SO}_3\text{NH}_2$  by mixing with HNO<sub>3</sub> and passing in nitrous acid gas (Hypheneth, *A.* 221, 205). Minute orange needles.

#### *p*-Diazo-benzene sulphonic acid

$\text{C}_6\text{H}_4\text{SO}_3\text{N}_2$ . Formed by diazotising *p*-amido-benzene sulphonic acid (Schmitt, *A.* 120, 144; Fischer, *A.* 190, 76). Small needles (from water). Insol. cold water, v. sol. water at 60°. Boiling water forms phenol *p*-sulphonic acid. An alkaline solution gives a red colour with aldehydes (Petri, *H.* 8, 291; Zahn, *B.* 17, Ref. 290), but this is not a characteristic test for aldehydes, as

it is given also by many other bodies (E. Fischer, *B.* 16, 667; O. Loew, *J. pr.* [2] 31, 136).

**Reactions.**—1. *Boiling alcohol* forms benzene sulphonic acid. 2.  $\text{PCl}_5$  at  $100^\circ$  has no action (Laur, *J. pr.* [2] 20, 263).

**Ethyl mercaptan**  $\text{C}_2\text{H}_5(\text{SO}_2\text{H})\text{N}$ . SET. Formed by combining *p*-diazobenzene-sulphonic acid with an alkaline solution of ethyl mercaptan. The sodium salt ( $\text{Na}$ ) forms yellow glistening needles, v. s. sol. water. It is very unstable, readily decomposing with evolution of nitrogen. When boiled with alcohol it yields ethyl-phenyl-sulphide *p*-sulphonic acid  $\text{C}_6\text{H}_4(\text{S}_2\text{C}_2\text{H}_5)(\text{SO}_2\text{H})$  (Stadler, *B.* 17, 2075).

**Methyl anilide**  $\text{C}_6\text{H}_4(\text{SO}_2\text{H})\text{N} \cdot \text{NM} \cdot \text{C}_2\text{H}_5$ . Formed by combination of *p*-diazobenzene-sulphonic acid with mono-methyl aniline in nearly neutral solution. The sodium salt ( $\text{NaA}$ ) forms large colourless plates, v. s. sol. water, from which it is precipitated in white felted needles by alkali; nearly insol. alcohol. Not affected by boiling with dilute caustic soda. Acid resolves it into its constituents *p*-diazobenzene-sulphonic acid and methyl aniline, which when the acid is dilute recombine to form methyl-amido-benzene-azo-benzene-sulphonic acid  $\text{C}_6\text{H}_4(\text{SO}_2\text{H})\text{N} \cdot \text{N} \cdot \text{C}_6\text{H}_4\text{NHMe}$  (Berthsen & Goske, *B.* 20, 926).

**Piperidine**  $\text{C}_6\text{H}_4(\text{SO}_2\text{H})\text{N} \cdot \text{NC}_4\text{H}_9$  (Wallach, *A.* 235, 270). From sulphamic acid by diazotisation and treatment with piperidine (1 mol.) and aqueous  $\text{NaOH}$  (1 mol.). Salt. —  $\text{NaA}$ : satiny plates. AgA: Stable in neutral or alkaline solutions.

**Imide**  $\text{C}_6\text{H}_4(\text{SO}_2\text{H})\text{N} \cdot \text{N} \cdot \text{C}_6\text{H}_4$  (1:1).

**Triazobenzene *p*-sulphonic acid**. Formed by the action of phenyl hydrazine upon diazobenzene-sulphonic acid suspended in cold water; diazobenzene-imide, sulphamic acid, and aniline, are formed simultaneously:

$\text{C}_6\text{H}_4(\text{N}_2\text{SO}_2\text{H})\text{N} \cdot \text{C}_6\text{H}_4\text{N}_2 + \text{C}_6\text{H}_4(\text{NH})\text{SO}_2\text{H} + \text{C}_6\text{H}_5\text{NH}_2$ . White deliquescent needles. V. s. sol. alcohol and water. Salts.  $\text{BaA}$ : 2aq; white six-sided plates, m. sol. hot water. **Phenyl hydrazine salt**  $\text{C}_6\text{H}_4\text{N}_2\text{H}_2\text{A}$ : long white glistening plates, m. sol. hot water and alcohol, less in the cold, nearly insol. ether and chloroform; decomposed by alkalis, but not by  $\text{HCl}$  even when boiling (Griess, *B.* 20, 1528).

**Diazo-benzene disulphonic acid**

$\text{C}_6\text{H}_4(\text{SO}_2\text{H}) \cdot \text{N} \begin{array}{c} \diagup \text{N}_2 \diagdown \\ \diagdown \text{SO}_2 \diagup \end{array}$ . The salts are formed by passing nitrous acid gas at  $0^\circ$  into a solution of the acid salts of  $\text{C}_6\text{H}_4(\text{NH})_2(\text{SO}_2\text{H})_2$  (1:3:4). The free acid is unstable (Zander, *A.* 198, 24). —  $\text{KA}$ :  $\text{BaA}$ : 2aq.

**Diazo-benzene disulphonio acid**

$\text{C}_6\text{H}_4(\text{SO}_2\text{H})(\text{SO}_2\text{N}_2)$ . Formed by diazotising  $\text{C}_6\text{H}_4(\text{NH})_2(\text{SO}_2\text{H})_2$  (1:3:5). Slender needles; v. sol. water and alcohol. Decomposed by  $\text{NaOH}$  or  $\text{BaCO}_3$ . The salts are formed by diazotising salts of the amido-benzene disulphonic acid (Heinzelmann, *A.* 188, 174; 190, 223). —  $\text{KA}$ : —  $\text{BaA}$ : 3aq. —  $\text{PbA}$ : 3aq.

**Diazo-benzene disulphonic acid**

$\text{C}_6\text{H}_4(\text{SO}_2\text{H})(\text{SO}_2\text{N}_2)$ . Formed by diazotising  $\text{C}_6\text{H}_4(\text{NH})_2(\text{SO}_2\text{H})_2$  (1:2:1).

**Salts.** —  $\text{NH}_4\text{A}$ . —  $\text{KA}$ . —  $\text{CaA}$ : 2aq. —  $\text{BaA}$ : 2aq. —  $\text{PbA}$ : 3aq (Heinzelmann & Zander, *A.* 198, 5).

**Diazo-benzene *p*-toluide** is identical with diazo-toluene anilide (q. v.).

***o* Diazo-benzoic acid.**

**Nitrate**  $\text{NO}_2\text{N}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ . By diazotisation of *o*-amido-benzoic acid suspended in dilute  $\text{HNO}_3$  (Griess, *B.* 9, 1653). Colourless tables or prisms, v. e. sol. water, m. sol. alcohol. Explodes when heated. Boiling water converts it into salicylic acid. Repeated solution in water and ppt. with alcohol converts it into the so-called semi-nitrate:

substance is also formed by passing nitrous acid gas into an alcoholic solution of *o*-amido-benzoic acid (Griess, *A.* 117, 39; Handl, *A.* 234, 116).

**Perbromide**  $\text{C}_6\text{H}_4\text{N}_2\text{O}_2\text{Br}_2$ .

**Imide**  $\text{N}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ . **Triazobenzoic acid** (115). From the perbromide and ammonia (Griess, *Z.* [2] 3, 165). Long needles. M. sol. boiling water.

***m*-Diazo-benzoic acid.**

**Sulphate**  $\text{SO}_3\text{H} \cdot \text{N}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ . Formed by passing nitrous acid gas into a thin paste of the sulphate of *m*-amido-benzoic acid; ppd. by alcohol and ether. Long white laminae, v. e. sol. water; detonates when heated. Treatment with dilute alcohol gives rises to a 'basic sulphate'  $\text{C}_6\text{H}_4\text{N}_2\text{O}_2 \cdot \frac{1}{2} \text{H}_2\text{SO}_4$  (?), or more probably  $[\text{N}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}]_2 \cdot \text{H}_2\text{SO}_4$ .

**Nitrate**  $\text{NO}_2\text{N}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$  (Griess, *A.* 120, 126). Its aqueous solution left in contact with  $\text{BaCO}_3$  forms carboxy-benzene-azo-oxy-benzoic acid. With aqueous  $\text{Na}_2\text{CO}_3$  it forms an acid  $\text{C}_6\text{H}_4\text{N}_2\text{O}_2$ .

**Hydrazide**  $\text{HO} \cdot \text{N}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ . Unstable yellow oil.

**Chloride**  $\text{ClN}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ . **Combinations.** —  $(\text{ClN}_2\text{C}_6\text{H}_4\text{CO}_2\text{H})_2 \cdot \text{PtCl}_4$ ; yellow prisms. —  $(\text{ClN}_2\text{C}_6\text{H}_4\text{CO}_2\text{H})\text{AuCl}_4$ . This salt suspended in alcohol and treated with  $\text{H}_2\text{S}$  gives benzoic acid, chloro-benzoic acid, and sulphhydro-benzoic acid,  $\text{HS} \cdot \text{C}_6\text{H}_4\text{CO}_2\text{H}$  (Griess, *J. pr.* [2] 1, 102).

**Perbromide**  $\text{Br}_2\text{N}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ . Oily pp. Converted by boiling alcohol into *m*-bromobenzoic acid (Griess, *A.* 135, 121; Cunze & Heßner, *A.* 135, 106).

**Ethyl ether; nitrate.**  $\text{NO}_2\text{N}_2\text{C}_6\text{H}_4\text{CO}_2\text{Et}$ . Formed by diazotising *m*-amido-benzoic ether dissolved in nitric acid (Griess, *A.* 120, 127). — **Aurochloride**  $(\text{ClN}_2\text{C}_6\text{H}_4\text{CO}_2\text{Et})\text{AuCl}_4$ ; golden prisms (from alcohol).

**Amide; nitrate.**  $\text{NO}_2\text{N}_2\text{C}_6\text{H}_4\text{CONH}_2$ . Formed by the action of nitrous acid gas on a solution of *m*-amido-benzamide in alcohol mixed with ether (Griess, *A.* 120, 127). Needles. **Platinochloride**  $(\text{ClN}_2\text{C}_6\text{H}_4\text{CONH}_2)_2 \cdot \text{PtCl}_4$ .

**Imide**  $\text{N}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ . **Triazobenzoic acid** (160). From the perbromide and  $\text{NH}_3$  (Griess, *Z.* 1867, 164). Thin laminae. V. sol. alcohol and ether, m. sol. boiling water. By heating with  $\text{HCl}$  it is converted into two isomeric chloro-amido-benzoic acids, (1, 3, 1) and (2, 3, 1):

**Anilide** *c.* **DIAZO-BENZENE-AMIDO-BENZOIC ACID.**

**Bromo-anilide** *c.* **DIAZO-BROMOBENZENE-AMIDO-BENZOIC ACID.**

**Nitrile.** Nitrate  $\text{NO}_2\text{N}_2\text{C}_6\text{H}_4\text{CN}$ . From *m*-amido-benzonitrile (Griess, *B.* 2, 370). Explosive crystals; m. sol. cold water.—**Perbromide**  $\text{Br}_2\text{N}_2\text{C}_6\text{H}_4\text{CN}$ . Crystals.—**Imide**  $\text{N}_2\text{C}_6\text{H}_4\text{CN}$ . [57]. Needles, v. sl. sol. water.

***p*-DIAZO-benzoic acid.**

**Nitrate**  $\text{NO}_2\text{N}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ . Explosive white prisms (Griess, *J.* 1861, 353).

**Amide.** Nitrate.  $\text{NO}_2\text{N}_2\text{C}_6\text{H}_4\text{CONH}_2$  (Griess, *Z.* 1866, 1).

**Imide**  $\text{N}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ . **Triazobenzoic acid.** [185]. Thin lamina (Griess, *Z.* 1867, 161).

***m*-DIAZO-benzoic-*m*-amido-benzoic acid** [3:1]  $\text{CO}_2\text{H.C}_6\text{H}_3\text{N}_2\text{NHC}_6\text{H}_4\text{CO}_2\text{H}$  [1:3].

Formed by passing nitrous acid gas into an alcoholic solution of *m*-amido-benzoic acid, or by mixing aqueous solutions of *m*-amido-benzoic acid and the nitrate of *m*-diazo-benzoic acid (Griess, *J.* 117, 2; *Z.* 1861, 353). Orange grains. Explodes at 180°. V. sl. sol. water, alcohol, and ether. Sol. alkalis and reprod. by acids. Boiling HCl forms *m*-amido-benzoic acid and *m*-chloro-benzoic acid. Bromine water gives bromo-, and tri-bromo-, benzoic acid. Boiling water and iodine form iodo-oxy-benzoic acid. Nitrous acid passed into a boiling aqueous solution forms nitro-oxy-benzoic acid; nitrous acid passed into a boiling alcoholic solution forms benzoic acid. Fuming  $\text{HNO}_3$  gives tri-nitro-oxy-benzoic acid.

Salts.  $(\text{NH}_4)^+\text{A}^-$ .  $\text{K}^+\text{A}^-$ .  $\text{Ag}^+\text{A}^-$ .

**Methyl ether**  $\text{Me}^+\text{A}^-$ . 160°. Yellow needles.

**Ethyl ether**  $\text{Et}^+\text{A}^-$ . 144°. Golden needles.

***p*-DIAZO-benzoic-*p*-amido-benzoic acid**

[4:1]  $\text{CO}_2\text{H.C}_6\text{H}_4\text{N}_2\text{NHC}_6\text{H}_4\text{CO}_2\text{H}$  [1:1]. Orange powder, v. sl. sol. boiling alcohol. Formed by passing nitrous acid gas into an alcoholic solution of *p*-amido-benzoic acid (Beilstein a. Wilbrand, *J.* 128, 269).

***m*-DIAZO-benzoic-*p*-amido-benzoic acid**

[3:1]  $\text{CO}_2\text{H.C}_6\text{H}_4\text{N}_2\text{NHC}_6\text{H}_4\text{CO}_2\text{H}$  [1:1]. From the nitrate of *m*-diazo-benzoic acid and *p*-amido-benzoic acid (Griess, *J.* 1861, 353). An isomeric (?) acid is got from the nitrate of *p*-diazo-benzoic acid and *m*-amido-benzoic acid.

***m*-DIAZO-bromobenzene.**

**Perbromide**  $\text{C}_6\text{H}_3\text{Br}_2\text{N}_2$  (Wurster, *J.* 176, 173).

***p*-DIAZO-bromobenzene.**

**Nitrate**  $\text{C}_6\text{H}_4\text{BrN}_2\text{NO}_2$ . Formed by passing nitrous acid gas into an aqueous solution of *p*-bromo-aniline nitrate (Griess, *Tr.* 1861, iii. 635). Ppl. by alcohol and ether.

**Hydroxide**  $\text{C}_6\text{H}_3\text{BrN}_2\text{OH}$ : bright yellow needles. Very explosive.  $\text{C}_6\text{H}_3\text{BrN}_2\text{OK}$ . From the nitrate and strong KOH; gives the preceding body when treated with acetic acid.  $\text{C}_6\text{H}_3\text{BrN}_2\text{OAg}$ .

**Bromide**  $\text{C}_6\text{H}_3\text{Br}_2\text{Br}$ : scales; v. sol. water, m. sol. alcohol, insol. ether.  $(\text{C}_6\text{H}_3\text{Br}_2\text{N}_2\text{Br})_2\text{PtBr}_2$ .

**Perbromide**  $\text{C}_6\text{H}_3\text{Br}_2\text{Br}_2$ : monoclinic prisms (from alcohol), v. sl. sol. ether, insol. water.

**Chloride**  $\text{C}_6\text{H}_4\text{BrN}_2\text{Cl}$ : from the bromide and moist silver chloride.  $(\text{C}_6\text{H}_4\text{BrN}_2\text{Cl})\text{AuCl}$ .  $(\text{C}_6\text{H}_4\text{BrN}_2\text{Cl})\text{PtCl}_2$ .

**Sulphate**  $\text{C}_6\text{H}_4\text{BrN}_2\text{SO}_4\text{H}$ : slender prisms.

**Imide**  $\text{C}_6\text{H}_4\text{BrN}_2$ . **Triazo-bromo-benzene**. [20?]. Insol. water, m. sol. alcohol, v. sol. ether and benzene. Reduced by Zn and  $\text{H}_2\text{SO}_4$  to bromo-aniline and NH<sub>3</sub>.

**Cyanide**  $\text{C}_6\text{H}_3\text{BrN}_2\text{CNHCN}$ . [128]. From *p*-diazo-bromo-benzene nitrate and aqueous KCN (Gabriel, *B.* 12, 1638).

**Anilide**  $\text{C}_6\text{H}_3\text{BrN}_2\text{NHC}_6\text{H}_5$  or, alternatively  $\text{C}_6\text{H}_3\text{BrN}_2\text{NHC}_6\text{H}_4\text{Br}$ . Formed either from diazo-benzene nitrate and *p*-bromo-aniline or from *p*-diazo-bromo-benzene nitrate and aniline (Griess, *B.* 7, 1618). Yellow plates; v. c. sol. ether, m. sol. alcohol.  $(\text{C}_6\text{H}_3\text{BrN}_2\text{NHC}_6\text{H}_4\text{Br})_2\text{PtCl}_2$ .

***p*-Bromo-anilide**  $\text{C}_6\text{H}_4\text{BrN}_2\text{NHC}_6\text{H}_4\text{Br}$ . [145]. Obtained from *p*-bromo-aniline.  $(\text{C}_6\text{H}_3\text{Br}_2\text{N}_2)_2\text{H}_2\text{PtCl}_6$ .

**DIAZO-di-bromobenzene.**

**Nitrate**  $\text{C}_6\text{H}_2\text{Br}_2\text{N}_2\text{NO}_2$  [2:4:1]. Obtained by passing nitrous acid into an aqueous solution of the nitrate of di-bromo-aniline (Griess, *Tr.* 1861, iii. 701). Needles or plates.

**Platinochloride**  $(\text{C}_6\text{H}_2\text{Br}_2\text{N}_2)_2\text{H}_2\text{PtCl}_6$ : orange plates.

**Perbromide**  $\text{C}_6\text{H}_2\text{Br}_4\text{N}_2$ : slender needles.

**Imide**  $\text{C}_6\text{H}_2\text{Br}_2\text{N}_2$  [62]: needles.

**Di-bromo-anilide**

$\text{C}_6\text{H}_2\text{Br}_2\text{N}_2\text{NHC}_6\text{H}_4\text{Br}_2$ . [168]. From (2,4,1)-di-bromo-aniline. Golden needles, v. sl. sol. alcohol and ether.

**DIAZO-tri-bromobenzene.**

**Nitrate**  $\text{C}_6\text{H}_2\text{Br}_3\text{N}_2\text{NO}_2$  [2:4:6:1]. Formed when a rapid current of nitrous acid gas is passed into alcohol containing tri-bromo-aniline in suspension together with excess of  $\text{HNO}_3$ . As soon as everything is dissolved, ether is added and a bright yellow crystalline pp. of the diazonitrate is formed (H. Silberstein, *J. pr.* [2] 27, 102).

**Properties.**—Yellow trimetric plates. Explodes at 85°. Sol. water and HCl. V. sl. sol. alcohol, ether, and benzene.

**Reactions.**—1. Boiled with alcohol it gives tri-bromobenzene,  $\text{N}_2$ ,  $\text{HNO}_3$ , and aldehyde. — 2. Boiled with water, gives off no nitrogen but forms undetermined compounds. — 3. Heated with glacial acetic acid gives off  $\text{N}_2$  and nitrous fumes and leaves tri-bromobenzene. — 4. Heated with benzene (1 pts.) it decomposes at 15° forming a diazo-di-bromo-phenol (*q. v.*), tetra-bromobenzene [98], and nitrobenzene. — 5. Heated with  $\text{CHCl}_3$  it gives diazo-di-bromo-phenol and tetra-bromobenzene. — 6. Heated with concentrated HCl it forms crystals of the perbromide of diazo-tri-bromo-benzene chloride,  $\text{C}_6\text{H}_2\text{Br}_3\text{N}_2\text{ClBr}_2$ . Probably chlorine, liberated in this reaction, turns out bromine from some of the tri-bromo-compound, which bromine then unites with the diazo-chloride. The perbromide explodes at 100°, forming chloro-tri-bromo-benzene. — 7. With HBr it gives the bromide (*q. v.*). — 8. With HI it gives tri-bromo-iodo-benzene.

**Sulphate**  $\text{C}_6\text{H}_2\text{Br}_3\text{N}_2\text{SO}_4\text{H}$ .

**Properties.**—Colourless prisms. Sol. water, sl. sol. alcohol, insol. ether and benzene.

**Reactions.**—1. Decomposed by alcohol into tri-bromobenzene,  $\text{H}_2\text{SO}_4$ , and  $\text{N}_2$ . — 2. Boiled with acidulated water it forms no tri-bromo-phenol. — 3. Heated with glacial acetic acid it forms tri-bromobenzene. — 4. Not affected by boiling benzene.

**Bromide**  $\text{C}_6\text{H}_2\text{Br}_3\text{N}_2\text{Br}$ . Small golden tri-

metric tablets, got by adding dilute HBr to a solution of the nitrate. Decomposed by sunlight into N<sub>2</sub> and C<sub>6</sub>H<sub>3</sub>Br<sub>3</sub>. Sl. sol. water, insol. alcohol and ether. Heated with glacial acetic acid it gives unsymmetrical C<sub>6</sub>H<sub>3</sub>Br<sub>3</sub>.

**Perbromide** C<sub>6</sub>H<sub>2</sub>Br<sub>5</sub>N<sub>2</sub>Br<sub>2</sub>. Formed by adding conc. HBr to a solution of the nitrate, C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>N<sub>2</sub>NO<sub>2</sub>; the liquid is filtered from C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>N<sub>2</sub>Br and evaporated to crystallisation. It forms orange prisms and behaves very much like C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>N<sub>2</sub>ClBr<sub>2</sub> (q. v.).

**Chloro-perbromide** C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>N<sub>2</sub>ClBr<sub>2</sub>. From tri-bromo-diazo-benzene nitrate (q. v.) and HCl. It explodes at 100° forming chloro-tri-bromo-benzene. **Reactions.**—1. With NH<sub>3</sub> gives tri-bromo-diazo-benzene imide (q. v.).—2. With alcoholic dimethylaniline forms tri-bromo-benzene-azo-dimethylaniline C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>N<sub>2</sub>C<sub>6</sub>H<sub>4</sub>NMe<sub>2</sub>.—3. With alcoholic methyl-di-phenylamine it forms tri-bromo-benzene-azo-methyl-di-phenylamine C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>N<sub>2</sub>C<sub>6</sub>H<sub>4</sub>NMePh. —4. With mercuric diphenyl it forms chloro-tri-bromo-benzene and nitrogen (Silberstein, *J. pr.* [2] 27, 117).

**Imide** C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>N<sub>2</sub>. (59°). Formed by adding dilute ammonia to C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>N<sub>2</sub>ClBr<sub>2</sub>. Colourless needles. May be distilled with steam. Insol. water, sol. warm alcohol, ether, and CHCl<sub>3</sub>. Unlike diazo benzene-imide, it is not reduced by Zn and H<sub>2</sub>SO<sub>4</sub> to NH<sub>3</sub> and tri-bromo-aniline (Silberstein, *J. pr.* [2] 27, 116).

**Anilide** C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>N<sub>2</sub>NHPh. (101°). From alcoholic aniline (2 mols.) and C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>N<sub>2</sub>NO<sub>2</sub> (1 mol.). The pp. is crystallised from alcohol (Silberstein, *J. pr.* [2] 27, 121). Yellow, glittering, triclinic prisms. Insol. water, sol. hot alcohol, ether and benzene. Boiled with glacial acetic acid it gives nitrogen and tri-bromo-aniline.

**Tri-bromo-anilide** C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>N<sub>2</sub>NH.C<sub>6</sub>H<sub>4</sub>Br<sub>3</sub>. Obtained by passing N<sub>2</sub>O slowly into a cold alcoholic solution of tri-bromaniline. Some C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>N<sub>2</sub>NO<sub>2</sub> is formed at the same time. The product is washed with water and hot alcohol and crystallised from benzene. The yield is bad (Silberstein, *J. pr.* [2] 27, 120). Insol. water and alcohol, v. sl. sol. ether. V. sol. CHCl<sub>3</sub> and benzene. Not attacked by cold acids, but decomposed by boiling with acids with evolution of N<sub>2</sub>.

**Diazo-p-bromo-benzene-amido-benzoic acid** C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>N<sub>2</sub>NH.C<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H. **Diazo-benzoic acid p-bromo-anilide.** From p-diazo-bromo-benzene nitrate and m-amido-benzoic acid (Griess, *J.* 1866, 453). Clusters of needles.

**Diazo-bromo-benzene sulphonic acid** C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub><SO<sub>3</sub>H> [4?]. From the corresponding bromo-amido-sulphonic acid (Borns, *A.* 187, 371). Small yellow needles, v. sol. water, m. sol. alcohol; explodes when struck or when heated. Heated with alcohol, it gives m-bromo-benzene sulphonic acid. Conc. HBr gives C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>(SO<sub>3</sub>H) [4:1:2].

**Diazo-bromo-benzene disulphonic acid**

From C<sub>6</sub>H<sub>2</sub>(NH<sub>2</sub>)<sub>2</sub>(SO<sub>3</sub>H)<sub>2</sub>Br [1:4:6:2]. Minute plates; v. sol. water and alcohol. Does not explode when struck (Zander, *A.* 198, 15).—*K&S* say.

**From C<sub>6</sub>H<sub>2</sub>(NH<sub>2</sub>)<sub>2</sub>Br<sub>2</sub>(SO<sub>3</sub>H)<sub>2</sub>**

[1:2:6:4]. Yellowish scales; explodes above 100°. V. sl. sol. cold water, v. sol. hot water. Boiling water gives di-bromo-phenol sulphonic acid. Heated with alcohol it gives di-bromo-benzene sulphonic acid.

**Diazo-di-bromo-benzene-sulphonic-acid-di-bromo-sulphanilide**

C<sub>6</sub>H<sub>2</sub>Br<sub>4</sub>(SO<sub>3</sub>H)<sub>2</sub>N<sub>2</sub>NH.C<sub>6</sub>H<sub>4</sub>Br<sub>2</sub>(SO<sub>3</sub>H)<sub>2</sub>. [70°-80°]. From C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>(NH<sub>2</sub>)<sub>2</sub>SO<sub>3</sub>H [2:4:1:5] by warming with alcohol and KNO<sub>3</sub>. Needles (from water). Insol. alcohol (Baessmann, *A.* 191, 229).

**Diazo-di-bromo-benzene-disulphonic acid**

C<sub>6</sub>HBr<sub>2</sub>(SO<sub>3</sub>H)<sub>2</sub><SO<sub>3</sub>H>. From the nitro-benzene disulphonic acid [1:3:5]? whose chloride melts at 96°, by reduction, bromination, and diazotisation (Heinzelmann, *A.* 188, 183).

**Diazo-tri-bromo-benzene sulphonic acid**

C<sub>6</sub>HBr<sub>3</sub><SO<sub>3</sub>H>. From tri-bromo-aniline, C<sub>6</sub>H<sub>2</sub>(NH<sub>2</sub>)<sub>2</sub>Br<sub>3</sub> [1:3:4:5] by sulphonation and diazotisation (Spiegelberg, *A.* 197, 291). Minute needles.

**Diazo-tetra-bromo-benzene p-sulphonic acid**

C<sub>6</sub>Br<sub>4</sub><SO<sub>3</sub>H>. Crystalline powder not decomposed by boiling alcohol (Beckurts, *A.* 131, 225).

**Diazo-bromo-nitro-toluene sulphonic acid**

C<sub>6</sub>HMeBr(NO<sub>2</sub>)<N<sub>2</sub>>. Formed by projecting m-bromo-p-amido-toluene o-sulphonic acid into fuming HNO<sub>3</sub> (Weckwarth, *A.* 172, 203).

**Diazo-di-bromo-nitro-toluene sulphonic acid**

C<sub>6</sub>Br<sub>2</sub>Me(NO<sub>2</sub>)<N<sub>2</sub>>. Formed by projecting di-bromo-o-amido-toluene p-sulphonic acid into fuming HNO<sub>3</sub> (Haydick, *A.* 174, 355).

**Diazo-di-bromo-phenol**

**Preparation.**—Bromine water is added to an aqueous solution of o-diazo-phenol chloride and the pp. is dissolved in fuming HCl, filtered through asbestos and ppd. by water.

**Properties.**—Orange crystalline powder, much less stable than the p-compound. When heated it explodes at 128°. It is more soluble in cold water than the p-compound; on warming the solution a resin is formed. The solution gives an amorphous grey pp. with silver nitrate. It is almost insoluble in alcohol, ether and CS<sub>2</sub>, but readily dissolves in CHCl<sub>3</sub>, hot benzene, and benzoline. It does not reduce Fehling's solution, nor form a crystalline body with NaHSO<sub>3</sub>. C<sub>6</sub>H<sub>2</sub>Br<sub>2</sub>(OH)<sub>2</sub>N<sub>2</sub>Br<sub>2</sub>aq: decomposed by water.

**Ethyl-ether, nitrate of.**

C<sub>6</sub>H<sub>2</sub>Br<sub>2</sub>(OEt)<sub>2</sub>N<sub>2</sub>NO<sub>2</sub>. Got by passing N<sub>2</sub>O into alcohol containing HNO<sub>3</sub> and di-bromo-o-amido-phenetol in suspension, and pouring it into dry ether at 0°. **Properties.**—Prisms. Explodes at 102°. If its alcoholic solution be diluted with water (10 vols.) and boiled as long as N<sub>2</sub> escapes, it is converted into di-bromo-phenetol, bromine being replaced by hydrogen, not by hydroxyl (Möhlau & Oehmichen, *J. pr.* [2] 24, 482).

### Diazo-di-bromo-phenol

**Formation.**—1. Obtained by adding bromine water to an aqueous solution of any salt of *p*-diazophenol:  $\text{C}_6\text{H}_4(\text{OH})\text{N}_2\text{Cl} + 2\text{Br}_2 = \text{C}_6\text{H}_3\text{Br}_2 \left\langle \text{N}_2 \right\rangle + \text{HCl} + 2\text{HBr}$ .—2. From  $\text{HBr}$  and diazophenol nitrate (*q. v.*).

**Properties.**—A flocculent yellow pp. resembling sulphide of arsenic. Dissolves in boiling water, without decomposition, and crystallises in yellow prisms as the solution cools. Almost insoluble in cold water, ether, and  $\text{CS}_2$ , somewhat more soluble in  $\text{CHCl}_3$ . Soluble in alcohol and in amyl alcohol. May be kept for months in closed bottles in the dark, but, when exposed to air and light, it soon turns brown. Heated to  $137^\circ$  it explodes.

**Salts.**—Unstable, decomposed by water and by alcohol.  $\text{C}_6\text{H}_3\text{Br}_2(\text{OH})\text{N}_2\text{Br}$ , aq. —  $\{\text{C}_6\text{H}_3\text{Br}_2(\text{OH})\text{N}_2\text{Br}\}_2\text{PtCl}_6$ : triclinic plates, decomposed by water. —  $\text{C}_6\text{H}_3\text{Br}_2(\text{OH})\text{N}_2\text{SO}_3\text{H}$  (Böhmer, *J. pr.* 132, 458).

**Reactions.**—1. Boiled with water of which the boiling-point, by addition of calcic chloride, has been raised to  $120^\circ$ , it gives off nitrogen and forms di-bromo-hydroquinone:

(Böhmer, *J. pr.* 132, 464).—2. Dissolves in a hot solution of  $\text{NaHSO}_3$ ; and as the solution cools, yellow needles of  $\text{C}_6\text{H}_3\text{Br}_2(\text{OH})\text{N}_2\text{SO}_3\text{Na}$  are formed. These crystals dissolve in ether, benzene and  $\text{CS}_2$ ; do not explode when heated; show Liebermann's reaction; do not reduce Fehling's solution; and give with  $\text{BaCl}_2$  golden scales of  $\{\text{C}_6\text{H}_3\text{Br}_2(\text{OH})\text{N}_2\text{SO}_3\}_2\text{Ba}$  aq.—3. Reduced by  $\text{Sn}$  and  $\text{HCl}$  to di-bromo-*p*-amido-phenol.

**Diazo-di-bromo-phenol (?)** Identical with the preceding diazo-di-bromo-phenol just described may be converted into this isomeride by first reducing it to dibromo-*p*-amido-phenol hydrochloride and again diazotising.

**Properties.**—Explodes at  $145^\circ$ , has a greyish-yellow colour, is insoluble in water. Crystallises from alcohol in much thinner needles than the preceding. With  $\text{NaHSO}_3$  it forms small plates, whereas the sulphinate of its parent-isomeride crystallises in needles (Böhmer, *J. pr.* 132, 471).

### Diazo-di-bromo-phenol

$\text{C}_6\text{H}_3\text{Br}_2 \left\langle \text{N}_2 \right\rangle$ . [ $\text{Br}:\text{Br}:\text{N}:\text{O} = 1:5:6:3$ ]. Formed by heating tri-bromo-diazo-benzene nitrate with benzene at  $45^\circ$  (Silberstein, *J. pr.* [2] 27, 107).

**Properties.**—Oblique prisms, from water. Crystallises from alcohol. Explodes at  $142^\circ$ . Soluble in hot alcohol. Nearly insoluble, in chloroform and ether.

**Salts.**—These are very unstable; they are formed by warming with rather strong solutions of acids, but are saponified by water.

**Reactions.**—1. Not attacked by boiling water. 1. Heated with strong  $\text{HBr}$  forms tri-bromo-phenol and  $\text{N}_2$ .—3. Reduced by  $\text{Sn}$  and  $\text{HCl}$  to li-bromo-amido-phenol and  $\text{NH}_3$ .

**Constitution.**—The hydrochloride of the di-bromo-amido-phenol obtained by reduction, gives Schmitt's reaction upon the gradual addition of dilute bleaching powder, viz.: a violet colour

followed by a white pp. As this reaction is characteristic of *p*-amido-phenols, this body must be di-bromo-*p*-amido-phenol, and since it is formed from  $\text{C}_6\text{H}_3(\text{NH}_2)\text{Br}_2$  [1:3:4:6] its constitution is as given above. It appears to be different from Böhmer's compound, exploding at  $137^\circ$ .

### Diazo-tri-bromo-phenol.

*Ethyl ether*, nitrate of.

$\text{C}_6\text{HBr}_3(\text{OEt})\text{N}_2\text{NO}_2$  [ $\text{OEt}:\text{N}_2 = 1:2$ ]. Triclinic plates, prepared by bromination of *o*-diazophenol. Does not explode when struck. In melting-point tubes it explodes at  $93^\circ$ . It is decomposed by boiling water into tri-bromo-phenol, the  $\text{N}_2\text{NO}_2$  being displaced by  $\text{H}$ , not by  $\text{OH}$  (Möhlau a. Ochmichen, *J. pr.* 132, 484):

### Diazo-bromo-toluene sulphonic acids

$\text{CH}_3\text{C}_6\text{H}_3\text{Br} \left\langle \text{N}_2 \right\rangle \text{SO}_3$ . Five are known:

*p*-diazo-*m*-bromo-toluene *o*-sulphonic acid (Weekwarth, *A.* 173, 196). Red crystals. Heated with alcohol under pressure it gives bromo-toluene sulphonic acid.

*p*-diazo-bromo-toluene *m*-sulphonic acid (Fechmann, *A.* 173, 211). Heated with alcohol under pressure it gives bromo-toluene *m*-sulphonic acid.

diazo-*o*-bromo-toluene *m*-sulphonic acid (Schäfer, *A.* 174, 360).

diazo-*p*-bromo-toluene *m*-sulphonic acid (*S.*).

diazo-*p*-bromo-toluene *o*-sulphonic acid (*S.*).

*o*-Diazo-di-bromo-toluene *p*-sulphonic acid (Hayduck, *A.* 174, 352).

### Diazo-camphor v. CAMPHOR.

**Diazo-*p*-chloro-benzene** [1:4]  $\text{C}_6\text{H}_4\text{Cl.N}_2.\text{OH}$ . Yellow explosive powder, ppd. from its salts by  $\text{HOAc}$ . Salts.— $\text{C}_6\text{H}_4\text{Cl.N}_2.\text{NO}_2$ : white plates.— $\text{C}_6\text{H}_4\text{Cl.N}_2\text{Br}$ : yellow prisms.— $\text{C}_6\text{H}_4\text{Cl.N}_2\text{N} = (\text{C}_6\text{H}_4\text{Cl.N}_2\text{Cl})_2\text{PtCl}_6$  (Griess, *Tr.* 1864, iii, 705).

**Anilide v. Diazo-benzene *p*-chloro-anilide.**  
*p*-Chloro-anilide  $\text{C}_6\text{H}_4\text{Cl.N}_2.\text{NH.C}_6\text{H}_4\text{OH}$  [125°].

### Diazo-di-chloro-benzene.

**Salts.**— $\text{C}_6\text{H}_3\text{Cl}_2\text{N}_2\text{NO}_2$ . —  $\text{C}_6\text{H}_3\text{Cl}_2\text{N}_2\text{Br}$ . —  $(\text{C}_6\text{H}_3\text{Cl}_2\text{N}_2\text{Cl})_2\text{PtCl}_6$  (*G.*).

**Di-chloro-anilide**  $\text{C}_6\text{H}_3\text{Cl}_2\text{N}_2.\text{NH.C}_6\text{H}_4\text{Cl}$  [127°]. Needles, v. sl. sol. alcohol and ether.

### Diazo-chloro-nitro-phenol

$\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2) \left\langle \text{N}_2 \right\rangle$ . From chloro-nitro-amido-phenol (Griess, *A.* 113, 215). Brownish-red columns (from alcohol).

**Diazo-di-chloro-phenol**  $\text{C}_6\text{H}_3\text{Cl}_2 \left\langle \text{N}_2 \right\rangle$ . From  $\text{C}_6\text{H}_3(\text{OH})\text{Cl}_2(\text{NH}_2)$  [1:3:5:2] (Schmitt a. Glutz, *B.* 2, 52). Brown flocculent powder.

**Diazo-tri-chloro-phenol**  $\text{C}_6\text{HCl}_3 \left\langle \text{N}_2 \right\rangle$ . From

tri-chloro-*p*-amido-phenol (Lampert, *J. pr.* [3] 33, 375). Golden needles, explodes at  $187^\circ$ . Sl. sol. hot alcohol or benzene, insol. ether.

**Reactions.**—1. Boiling alcohol gives a tri-chloro-phenol [54°] ( $253^\circ$ ).—2. Conc.  $\text{Na}_2\text{SO}_3$  aq. forms  $\text{C}_6\text{HCl}_3(\text{ONa})\text{N}_2\text{SO}_3\text{Na}$ , of which the acid  $\text{C}_6\text{HCl}_3(\text{OH})\text{N}_2\text{SO}_3\text{H}$  explodes at  $200^\circ$ , and forms an orange crystalline barium salt.—3.  $\text{HI}$  forms  $\text{C}_6\text{HCl}_3\text{I.OH}$ .

### Diazo-chloro-thymol chloride

$\text{C}_6\text{HClMePr}(\text{OH})\text{N}_2\text{Cl}$ . By the action of  $\text{N}_2\text{O}$  on

a cold alcoholic solution of hydrochloride of chloro-amido-thymol (Andersen, *J. pr.* 181, 180). Precipitated by ether. Colourless needles, often grouped in fans.

**o-Diazo-cinnamic acid.** From amido-cinnamic acid (10 pts.), HCl (9 pts. of S.G. 1.19), water (70 pts.), and  $\text{NaNO}_2$ . The chloride separates as a yellow powder (Fischer & Kuzel, *B.* 14, 478; *A.* 221, 272). The nitrate  $\text{C}_6\text{H}_4(\text{N}_2\text{NO}_2)\cdot\text{CH}:\text{CH}\cdot\text{CO}_2\text{H}$  forms clear prisms. Both salts may be boiled with potash without giving off nitrogen, but they are decomposed by boiling water, forming *o*-coumaric acid. With  $\text{Na}_2\text{SO}_3$  they form  $\text{C}_6\text{H}_4(\text{N}_2\text{SO}_3\text{Na})\cdot\text{CH}:\text{CH}\cdot\text{CO}_2\text{H}$ , whence, by reducing with zinc and HCl,  $\text{C}_6\text{H}_4(\text{NH}_2\text{NH}_2\text{SO}_3\text{Na})\cdot\text{CH}:\text{CH}\cdot\text{CO}_2\text{H}$ . The latter forms slender needles. It reduces  $\text{HgO}$  in the cold, and Fehling's solution. HCl in the cold converts it into hydrazido-cinnamic acid (q. v.).

**p-Diazo-cinnamic acid.** The chloride  $\text{C}_6\text{H}_4(\text{N}_2\text{N}:\text{CH}:\text{CH}:\text{CO}_2\text{H})$  is prepared by the action of  $\text{NaNO}_2$  on *p*-amido-cinnamic acid suspended in HCl (Gabriel, *B.* 15, 2300). Long needles (containing aq.). M. sol. water. Can be dried at a gentle heat without decomposition.

**p-Diazo-cresol**  $\text{Me}\cdot\text{C}_6\text{H}_3(\text{N}_2)<\text{O}>$ . Formed by diazotising  $\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)(\text{OH})$  [1:3:4] (Wagner, *B.* 7, 1270)  $\rightarrow (\text{Me}\cdot\text{C}_6\text{H}_3(\text{OH})(\text{N}_2\text{Cl})\cdot\text{PtCl}_4$ ; powder, m. sol. water.

**Diazo- $\psi$ -cumene-sulphite.**

Salt.  $\text{C}_6\text{H}_4(\text{CH}_3)_2\cdot\text{N}_2\cdot\text{SO}_3\text{Na}$  [1:3:4:6]. Transparent prisms (containing  $2\frac{1}{2}$  aq.). Not explosive (Haller, *B.* 18, 90).

**Diazo- $\psi$ -cumene-cumide.** *Diazoamidocumene*. [1:3:4:6]  $\text{C}_6\text{H}_4\text{Me}_2\cdot\text{N}:\text{N}:\text{NH}\cdot\text{C}_6\text{H}_4\text{Me}_2$  [6:1:3:4]. [181°]. Formed by the combination of diazo-cumene with cumidine (Nölting & Böttmann, *B.* 18, 1147). Yellow tablets (from ether). V. sol. benzene, ether, and acetone, m. sol. alcohol.

**Diazo-cumino-amido-cuminic acid**  $\text{Pr}\cdot\text{C}_6\text{H}_3(\text{CO}_2\text{H})\cdot\text{N}_2\cdot\text{NH}\cdot\text{C}_6\text{H}_4\text{Pr}\cdot\text{CO}_2\text{H}$ . Formed by passing nitrous acid into an alcoholic solution of amido-cuminic acid at 0°. Minute prisms or leaflets (Griess, *A.* 117, 62).

**Diazo-ethane sulphite**  $\text{C}_6\text{H}_4\cdot\text{N}_2\cdot\text{SO}_3\text{H}$ . *Diazo-ethane sulphonic acid*.

Salt.  $\text{KA}$ . Formed by the action of  $\text{HgO}$  on the corresponding hydrazo-derivative  $\text{C}_6\text{H}_4\cdot\text{NH}\cdot\text{NH}\cdot\text{SO}_3\text{K}$  (Fischer, *A.* 199, 302). V. sol. water; pcd. by alcohol. Explodes when heated. Decomposed by boiling acids,  $\text{N}_2$  and  $\text{SO}_2$  coming off. Reduced by zinc-dust and acetic acid to  $\text{C}_6\text{H}_4\cdot\text{NH}_2\cdot\text{NH}_2\cdot\text{SO}_3\text{K}$ .

**Diazo-ethoxane**  $\text{C}_2\text{H}_5\cdot\text{O}\cdot\text{N}_2\cdot\text{O}\cdot\text{C}_2\text{H}_5$  (?) V.D. 4.02 (calc. 4.08). Prepared by the action of silver hyponitrite,  $\text{AgNO}_2$ , on  $\text{EtH}$  (Zorn, *B.* 11, 1630). Neutral liquid. Exceedingly explosive. Is decomposed by water with production of aldehyde and alcohol:  $(\text{C}_2\text{H}_5)_2\text{O}_2\text{N}_2 + \text{H}_2\text{O} = \text{N}_2 + \text{CH}_3\text{COH} + \text{C}_2\text{H}_5\text{OH} + \text{H}_2\text{O}$ . By tin and acetic acid it is reduced to nitro-ethane and alcohol:  $(\text{C}_2\text{H}_5)_2\text{O}_2\text{N}_2 + \text{H}_2 = 2\text{C}_2\text{H}_5\text{OH} + \text{N}_2$ .

**o-Diazo-hemipic acid**

$\text{C}_6\text{H}_4(\text{OMe})_2(\text{CO}_2\text{H})<\text{N}_2>\text{O}$ . *Diazo-di-methoxy-phthalic acid*. Formed by the action of nitrous acid upon *o*-amido-hemipic acid. Yellow micro-crystalline powder. Sl. sol. ordinary solvents. Explodes on percussion or when heated to

140°–160°. Converted into hemipic acid by boiling with alcohol.

**Hydrochloride**  $\text{C}_6\text{H}_4(\text{OMe})_2(\text{CO}_2\text{H})_2\cdot\text{N}_2\cdot\text{Cl}_2$ : long colourless needles.

The sulphate forms small prisms (Grüne, *B.* 19, 2302).

**Diazo-hippuric acid.**

The nitrate  $\text{CO}_2\text{H}\cdot\text{CH}_2\cdot\text{NH}\cdot\text{CO}\cdot\text{C}_6\text{H}_3\cdot\text{N}_2\cdot\text{NO}_2$  is formed by diazotising the nitrate of *m*-amido-hippuric acid (Griess, *Z.* 1867, 165).—**Perbromide**  $\text{C}_6\text{H}_3\text{NO}_2\cdot\text{N}_2\cdot\text{Br}_2$ : yellow prisms. **Imide**  $\text{C}_6\text{H}_4\text{NO}_2\cdot\text{N}_2$ : tables or needles.

**Diazo-leucaniline** v. Hexa-azo-tri-phenyl-methane (*infra*).

**p-Diazo-iodo-benzene**  $\text{C}_6\text{H}_4\cdot\text{I}\cdot\text{N}_2\cdot\text{OH}$ : yellow pp. Salts.— $(\text{C}_6\text{H}_4\cdot\text{I}\cdot\text{N}_2\cdot\text{Cl})\cdot\text{PtCl}_4$ — $\text{C}_6\text{H}_4\cdot\text{I}\cdot\text{N}_2\cdot\text{NO}_2$ — $\text{C}_6\text{H}_4\cdot\text{I}\cdot\text{N}_2\cdot\text{SO}_3\text{H}$ : small plates, v. sol. water, sl. sol. alcohol.— $\text{C}_6\text{H}_4\cdot\text{I}\cdot\text{N}_2\cdot\text{Br}_2$ .—**Imide**  $\text{C}_6\text{H}_4\cdot\text{I}\cdot\text{N}_2$  (Griess, *Tr.* 1864, iii, 706).

(a) **Diazo-naphthalene** (Griess, *J.* 1866, 469). **Nitrate**  $\text{C}_{10}\text{H}_7\cdot\text{N}_2\cdot\text{NO}_2$ : formed by diazotising  $\alpha$ -naphthylamine nitrate.—**Perbromide**  $\text{C}_{10}\text{H}_7\cdot\text{N}_2\cdot\text{Br}_2$ : orange crystals.—**Platino-chloride**  $(\text{C}_{10}\text{H}_7\cdot\text{N}_2\cdot\text{Cl})\cdot\text{PtCl}_4$ .—**Imide**  $\text{C}_{10}\text{H}_7\cdot\text{N}_2$ : yellowish oil (cf. Fischer, *A.* 232, 242).

A solution of the chloride neutralised by  $\text{Na}_2\text{CO}_3$  gives a brown pp. Part of this dissolves in alkalis and appears to be  $\text{C}_{10}\text{H}_7\cdot\text{NO}$ , the rest is pcd. as minute crystals by adding alcohol to its benzene solution. Analysis indicates  $\text{C}_{10}\text{H}_7\cdot\text{N}_2\cdot\text{O}$ . Both form crimson solutions in alcohol, ether, benzene, and glacial acetic acid (P. F. Frankland, *C. J.* 37, 750).

(b) **Diazo-naphthalene**. Obtained by diazotising (b)-naphthylamine (Liebmann & Palm, *A.* 183, 267). The sulphate forms pale yellow needles, and the perbromide orange needles.

$(\text{C}_{10}\text{H}_7\cdot\text{N}_2\cdot\text{Cl})\cdot\text{Cu}\cdot\text{Cl}_2$ : very unstable yellow pp. which is formed on adding  $\text{Cu}\cdot\text{Cl}_2$  to a cold solution of  $\beta$ -diazo-naphthalene-chloride.  $(\text{C}_{10}\text{H}_7\cdot\text{N}_2\cdot\text{Br})\cdot\text{Cu}\cdot\text{Br}_2$ : red pp.; on boiling with water it evolves nitrogen yielding (b)-bromo-naphthalene (Leilmann, *B.* 19, 810).

(a) **Diazo-naphthalene**-(a)-**naphthylamide**. [100°]. Formed by action of nitrous acid on (a)-naphthylamine, or by ppg. a solution of (a)-diazo-naphthalene chloride with (a)-naphthylamine. Brown laminae (from alcohol). Acids resolve it into naphthylamine and diazo-naphthalene (Martius, *Z.* [2] 2, 137).

(a) **Diazo-naphthalene sulphonic acid**

$\text{C}_{10}\text{H}_7<\text{N}_2>\text{SO}_3$ . [1:4]. Got by passing nitrous acid gas into (a)-naphthylamine sulphonic acid (formed by sulphonating (a)-naphthylamine) suspended in water (Clève, *Bl.* [2] 26, 241; Neville & Winther, *C. J.* 37, 632). Powder, nearly insoluble in cold water. Boiling water converts it into a crimson dye, forming very little naphthol sulphonic acid. Heated with dilute  $\text{H}_2\text{SO}_4$  (a)-naphthol *p*-sulphonic acid is formed. By heating with strong  $\text{H}_2\text{SO}_4$  or with water at 160°, (a)-naphthol is produced. Dilute  $\text{HNO}_3$  (7 to 15 p.c.  $\text{HNO}_3$ ) forms di-nitro-naphthol, [138°]. Conc.  $\text{HCl}$  forms a chloro-naphthalene sulphonic acid, whence  $\text{PCl}_5$  forms dichloro-naphthalene [68°].

**Imide**  $\text{C}_{10}\text{H}_7(\text{SO}_3\text{H})\cdot\text{N}<\text{N}>$  [1:4].

**Triazo-naphthalene-p-sulphonic acid**. Formed by the action of phenyl-hydrazine upon the

acid; diazo-benzene-imide, (α)-naphthylamine-*p*-sulphonic acid, and aniline are formed simul-

$\text{C}_6\text{H}_5(\text{N}_2)\text{SO}_3\text{H} + \text{C}_6\text{H}_5\text{N}_3 + \text{C}_6\text{H}_5(\text{NH}_2)\text{SO}_3\text{H} + \text{C}_6\text{H}_5\text{NH}_2$ . White needles. V. sol. water and alcohol.

Salt.—BaA': white silvery plates, v. sl. sol. boiling water. Phenyl-hydrazine salt  $\text{C}_6\text{H}_5\text{N}_2\text{H}_2\text{A}'$ : long plates; v. sol. alcohol, nearly insol. ether and chloroform (Griess, *B.* 20, 1530).

(α)-Diazo-naphthalene sulphonic acid

$\text{C}_{10}\text{H}_7\text{N}_2\text{SO}_3\text{H}$  [1:1' or 4']. Similarly prepared from the product of the reduction of (α)-nitro-(α)-naphthalene sulphonic acid formed by sulphonating nitro-naphthalene (Clève, *B.* [2] 24, 512). Yellow crystalline powder. Boiling water gives (α)-naphthol (α)-sulphonic acid.

(β)-Diazo-naphthalene sulphonic acid

$\text{C}_{10}\text{H}_7\text{N}_2\text{SO}_3\text{H}$ . Microcrystalline powder. Formed by diazotising (β)-naphthylamine sulphonic acid (formed by sulphonating (β)-naphthylamine). By boiling with HCl, converting into the K salt and heating with  $\text{PCl}_5$  it yields chloro-naphthalene-sulphonic chloride [129] (Forsling, *B.* 19, 1715).

(β)-Diazo-naphthalene sulphonic acid

$\text{C}_{10}\text{H}_7\text{N}_2\text{SO}_3\text{H}$ . Formed by diazotising (β)-naphthylamine sulphonic acid, itself got by the action of  $\text{NH}_3$  upon Schäffer's (β)-naphthol sulphonic acid at 180°. Minute crystals. Converted by treatment with cuprous chloride into (β)-chloro-naphthalene sulphonic acid, whose chloride melts at 110°, and, by distillation with  $\text{PCl}_5$  is converted into (ε)-di-chloro-naphthalene, [186°] (Forsling, *B.* 20, 80).

Tetrazo-dinaphthyl  $\text{HIO}_2\text{N}_4\text{C}_{10}\text{H}_7\text{C}_{10}\text{H}_7\text{N}_4\text{O}_2\text{OH}$ . Formed by diazotising naphthidine. It gives violet dye-stuffs when combined with the sulphonic acids of (β)-naphthol. By boiling with alcohol it yields (αα)-dinaphthyl.

Salts.— $\text{C}_{10}\text{H}_7\text{N}_2\text{SO}_3\text{Na}$ : yellowish plates. —  $(\text{C}_{10}\text{H}_7\text{N}_2\text{Cl}_2)\text{PtCl}_4$ : sparingly soluble yellow needles (Nietzki a. Goll, *B.* 18, 3256).

Diazo-nitro-benzaldoxim chloride

$\text{C}_6\text{H}_5(\text{NO}_2)(\text{N}:\text{NCl})(\text{CH}:\text{NOH})$  [3:1:1]. Formed by the action of amyl nitrite and HCl on (3:4:1)-nitro-amido-phenyl-acetic acid (Gabriel, *B.* 15, 837). Plates or needles. Explodes on heating. On heating with alcohol it gives *m*-nitro-benzaldoxim  $\text{C}_6\text{H}_5(\text{NO}_2)(\text{CH}:\text{NOH})$ .

*p*-Diazo-*o*-nitro-benzaldoxim chloride

$\text{C}_6\text{H}_3(\text{NO}_2)(\text{N}:\text{NCl})(\text{CH}:\text{NOH})$  [2:4:1]. Formed, with evolution of  $\text{CO}_2$ , by the action of amyl nitrite on a HCl solution of *o*-nitro-*p*-amido-phenyl-acetic acid (Gabriel a. R. Meyer, *B.* 14, 826; *C. C.* 1885, 516). Long red needles. Explosive. By the action of HBr it gives *o*-nitro-*p*-bromo-benzaldoxim. By hot alcohol it gives *o*-nitro-benzaldoxim  $\text{C}_6\text{H}_5(\text{NO}_2)(\text{CH}:\text{NOH})$ . On oxidation it gives *o*-nitro-benzaldehyde. Ammonium sulphide reduces it to *o*-amido-benzaldoxim  $\text{C}_6\text{H}_5(\text{NH}_2)(\text{CH}:\text{NOH})$  [133°].

*m*-Diazo-nitro-benzene. Formed by diazotising *m*-nitro-aniline.

Nitrate  $\text{C}_6\text{H}_5(\text{NO}_2)\text{N}_2\text{NO}_2$ : cubes. —  $(\text{C}_6\text{H}_5(\text{NO}_2)\text{N}_2\text{O})\text{PCl}_5$ — $\text{C}_6\text{H}_5(\text{NO}_2)\text{N}_2\text{Br}$  (Griess, *Z.* 1864, iii. 708).

Imide  $\text{C}_6\text{H}_5(\text{NO}_2)\text{N}_2$ . [32°].

*p*-Diazo-nitro-benzene. Formed by diazotising *p*-nitro-aniline.

Nitrate  $\text{C}_6\text{H}_5(\text{NO}_2)\text{N}_2\text{NO}_2$ : slender needles. Gives no pp. with  $\text{PCl}_5$ .

Imide  $\text{C}_6\text{H}_5(\text{NO}_2)\text{N}_2$ . [71°].

*m*-Diazo-nitro-benzene-*p*-ethyl-toluide

[3:1]  $\text{C}_6\text{H}_5(\text{NO}_2) - \text{N}_2 - \text{NEt}.\text{C}_2\text{H}_5\text{Me}$  [1:4]. [55°]. From *m*-diazo-nitro-benzene chloride and ethyl-*p*-toluidine (Gastiger, *B.* [2] 42, 312). Resolved by dilute HCl into its generators.

*p*-Diazo-nitro-benzene-*p*-ethyl-toluide

[4:1]  $\text{C}_6\text{H}_5(\text{NO}_2) - \text{N}_2 - \text{NEt}.\text{C}_2\text{H}_5\text{Me}$  [1:4]. [105°]. Yellow needles (Gastiger, *B.* [2] 42, 312). Resolved by HCl into *p*-diazo-nitro-benzene chloride and ethyl-*p*-toluidine.

*m*-Diazo-nitro-benzene-*m*-nitro-anilide

[3:1]  $\text{C}_6\text{H}_5(\text{NO}_2)\text{N}_2\text{NH}.\text{C}_6\text{H}_4(\text{NO}_2)$  [1:3]. [195°]. Formed by the action of nitrous acid (1 mol.) on *m*-nitro-aniline (2 mols.). Small red prisms, v. sl. sol. alcohol (Griess, *A.* 121, 272; Meldola a. Streatfield, *C. J.* 51, 107). Insol. hot aqueous KOH; but the potassium salt separates as brown crystals from a solution in alcoholic KOH. Cold HClAq gives *m*-nitro-aniline and *m*-diazo-nitro-benzene chloride.

*p*-Diazo-nitro-benzene-*p*-nitro-anilide

[4:1]  $\text{C}_6\text{H}_5(\text{NO}_2)\text{N}_2\text{NH}.\text{C}_6\text{H}_4(\text{NO}_2)$  [1:4]. [228°]. Formed by the action of nitrous acid (1 mol.) on *p*-nitro-aniline (2 mols.) (Griess, *A.* 121, 271; Meldola a. Streatfield, *C. J.* 49, 624). Small yellow needles, m. sol. boiling alcohol. Possesses distinctly acid properties, decomposing  $\text{Na}_2\text{CO}_3$ . Cold alcoholic KOH or boiling aqueous KOH form a magenta-coloured solution of the potassium salt. It forms *p*-nitro-aniline when heated with dilute  $\text{H}_2\text{SO}_4$  or with water in sealed tubes at 230°. Conc. HCl at 20° gives *p*-diazo-nitro-benzene chloride and *p*-nitro-aniline.

Salts.— $\text{C}_6\text{H}_5(\text{NO}_2)\text{N}_2\text{NNa}.\text{C}_6\text{H}_4\text{NO}_2$ : forms steel-blue needles, soluble only in excess of alkali. —  $\{\text{C}_6\text{H}_5(\text{NO}_2)\text{N}_2\}(\text{C}_6\text{H}_4\text{NO}_2)_2\text{Cu}$ . —  $\{\text{C}_6\text{H}_5(\text{NO}_2)\text{N}_2\}(\text{C}_6\text{H}_4\text{NO}_2)_2\text{Cl}$ . —  $\{\text{C}_6\text{H}_5(\text{NO}_2)\text{N}_2\}(\text{C}_6\text{H}_4\text{NO}_2)_2\text{Co}$ .

*m*-Diazo-nitro-benzene-*p*-nitro-anilide

[3 or 4:1]  $\text{C}_6\text{H}_5(\text{NO}_2)\text{N}_2\text{NH}.\text{C}_6\text{H}_4(\text{NO}_2)$  [1:4 or 8]. [211°]. From diazotised *m*-nitro-aniline hydrochloride and *p*-nitro-aniline; or from diazotised *p*-nitro-aniline hydrochloride and *m*-nitro-aniline (Meldola a. Streatfield, *C. J.* 51, 103, 439). Yellow needles (from alcohol). Dissolves in  $\text{NaOH}$ Aq, forming a red solution. Cold aqueous  $\text{H}_2\text{SO}_4$  gives *m*- and *p*-diazo-nitro-benzene chlorides and *m*- and *p*-nitro-aniline.

*m*-Diazo-nitro-benzene-*m*-nitro-benzyl-anilide [3:1]  $\text{C}_6\text{H}_5(\text{NO}_2)\text{N}_2\text{NC}_6\text{H}_4\text{C}_6\text{H}_5(\text{NO}_2)$  [1:8]. [142°]. From *m*-diazo-nitro-benzene-*m*-nitro-anilide, alcoholic KOH, and benzyl chloride (M. a. S.). HClAq at 100° gives *m*-chloro-nitro-benzene and *m*-nitro-benzyl-aniline.

*p*-Diazo-nitro-benzene-*p*-nitro-benzyl-anilide

[4:1]  $\text{C}_6\text{H}_5(\text{NO}_2)\text{N}_2\text{NC}_6\text{H}_4\text{C}_6\text{H}_5(\text{NO}_2)$  [1:4]. [190°]. From *p*-diazo-nitro-benzene-*p*-nitro-benzyl-anilide, alcoholic KOH, and  $\text{C}_6\text{H}_5\text{Cl}$  (Meldola a. Streatfield, *C. J.* 51, 112). Minute yellow needles. Conc. HCl decomposes it at 100° into *p*-nitro-benzyl-aniline and *p*-chloro-nitro-benzene.

**m-Diazo-nitro-benzene-m-nitro-ethyl-anilide** [4:1]  $C_6H_4(NO_2)_2N_2.C_2H_5.C_6H_4(NO_2)$  [1:3]. [180°]. From *m*-diazo-nitro-benzene-*p*-nitro-anilide alcoholic KOH, and benzyl chloride (Meldola a. Streatfield, *C. J.* 51, 114).

**m-Diazo-nitro-benzene-m-nitro-ethyl-anilide** [3:1]  $C_6H_4(NO_2)_2N_2.NEt.C_2H_5(NO_2)$  [1:3]. [119°]. From *m*-diazo-nitro-benzene-*m*-nitro-anilide by treatment with KOH and EtI. Also from *m*-diazo-*p*-nitro-benzene and *m*-nitro-ethyl-aniline. Needles. Cold conc. HCl forms *m*-diazo-nitro-benzene chloride and *m*-nitro-ethyl-aniline (Meldola a. Streatfield, *C. J.* 51, 108, 441).

**p-Diazo-nitro-benzene-p-nitro-ethyl-anilide** [4:1]  $C_6H_4(NO_2)_2N_2.NEt.C_2H_5(NO_2)$  [1:4]. [192°]. Formed by the action of EtI and KOH upon *p*-diazo-nitro-benzene-*p*-nitro-ethyl-anilide (Meldola a. Streatfield, *C. J.* 49, 631). Or from diazotised *p*-nitro-aniline and *p*-nitro-ethyl-aniline (M. a. S., *C. J.* 51, 111, 442). Yellow needles, v. sl. sol. alcohol, insol. alkalis. Decomposed by cold HCl into *p*-diazo-nitro-benzene chloride and *p*-nitro-ethyl-aniline.

**p-Diazo-nitro-benzene-m-nitro-ethyl-anilide** [4:1]  $C_6H_4(NO_2)_2N_2.NEt.C_2H_5(NO_2)$  [1:3]. [187°]. From diazotised *p*-nitro-aniline and *m*-nitro-ethyl-aniline (Meldola a. Streatfield, *C. J.* 51, 111, 442). Orange needles (from alcohol). V. sl. sol. alcohol. Cold conc. HCl gives *m*-nitro-ethyl-aniline and *p*-diazo-nitro-benzene chloride.

**m-Diazo-nitro-benzene-p-nitro-ethyl-anilide (?)**

[3:1]  $C_6H_4(NO_2)_2N_2.NEt.C_2H_5(NO_2)$  [1:4]. [148°]. Prepared by digesting the potassium salt of *m*-diazo-nitro-benzene-*p*-nitro-anilide dissolved in alcohol with EtI (Meldola a. Streatfield, *C. J.* 51, 105). Small yellow needles. Heated with HCl at 100° it gives *m*- and *p*-nitro-ethyl-anilines and *m*- and *p*-chloro-nitro-benzenes. By cold HCl it is resolved into *m*- and *p*-diazo-nitro-benzene chlorides and *m*- and *p*-nitro-ethyl-anilines.

**m-Diazo-nitro-benzene-p-nitro-ethyl-anilide** [3:1]  $C_6H_4(NO_2)_2N_2.NEt.C_2H_5(NO_2)$  [1:4]. [175°]. From diazotised *m*-nitro-aniline and *p*-nitro-ethyl-aniline (Meldola a. Streatfield, *C. J.* 51, 110). Yellow needles (from alcohol). V. sl. sol. alcohol. With conc. HCl aq it forms *p*-nitro-aniline and *m*-diazo-nitro-benzene chloride.

**p-Diazo-nitro-benzene-piperidine** [4:1]  $C_6H_4(NO_2)_2N_2.NC_4H_9$  [97°] (Wallach, *A.* 235, 264).

**m-Diazo-nitro-benzene sulphonie acid**

$C_6H_4(NO_2)_2 \begin{smallmatrix} \text{N}_2(1) \\ \text{SO}_3(6) \end{smallmatrix}$ . Formed by diazotisation of *m*-nitro-aniline sulphonie acid (1:3.6). White microscopic tables. By heating with absolute alcohol under an extra pressure of 400 mm. it is converted into *p*-nitro-benzene sulphonie acid (Limpriecht, *B.* 18, 2186).

**Diazo-nitro-benzene disulphonie acid**

$C_6H_4(SO_3H)(NO_2) \begin{smallmatrix} \text{N}_2 \\ \text{SO} \end{smallmatrix}$ . Formed by diazotising *m*-nitro-aniline disulphonie acid (Limpriecht, *B.* 8, 289). Boiling alcohol forms *m*-nitro-benzene disulphonie acid.

**Diazo-nitro-benzoic acid**

$C_6H_4(NO_2) \begin{smallmatrix} \text{N}_2 \\ \text{CO} \end{smallmatrix}$ . Explosive yellow laminas (Balkowski, *A.* 173, 63).

formed by diazotising nitro-amido-benzene-*o*-benzene (Nietzki a. Benkiser, *B.* 18, 501).  $C_6(NO_2)(N_2OH)(OH)(ONa)O_2$  aq: long yellow explosive needles.  $-C_6(NO_2)(N_2OH)(OH)(OAg)O_2$ : yellow explosive plates.

**Diazo-nitro-phenol**  $C_6H_4(NO_2) \begin{smallmatrix} \text{N}_2 \\ \text{O} \end{smallmatrix}$ . From  $C_6H_4(OH)(NH_2)(NO_2)$  [1:2:4] by diazotisation (Griess, *A.* 113, 212). Brownish-yellow granular mass; v. sl. sol. hot water, v. sol. alcohol. Explodes at 100°.

**Methyl ether.**

Nitrate  $C_6H_4(NO_2)(OMe).N_2.NO_2$ . Formed by diazotising nitro-anisidine (Griess, *J.* 1866, 459). Platinochloride  $C_6H_4(NO_2)(OMe).N_2.Cl_2.PtCl_2$ . Perbromide  $C_6H_4(NO_2)(OMe).N_2.Br_2$ . Imide  $C_6H_4(NO_2)(OMe).N_2$ : needles.

**Methoxy-nitraniide**

$C_6H_4(NO_2)(OMe).N_2.NH.C_2H_5(NO_2)(OMe)$ . Formed by passing nitrous acid into an alcohol solution of nitro-anisidine (Griess, *A.* 121, 278).

**Diazo-di-nitro-phenol**  $C_6H_3(NO_2)_2 \begin{smallmatrix} \text{N}_2 \\ \text{O} \end{smallmatrix}$ .

Formed by passing nitrous acid into an alcoholic solution of di-nitro-amido-phenol (picramic acid (Griess, *A.* 113, 205). Yellow plates (from alcohol).

**Diazo-nitro-β-phenyl-propionic acid**

[3:4:1]  $C_6H_4(NO_2)(N_2OH).C_6H_4.CO_2H$ . Nitro-diazo-hydrocinnamic acid. The nitrate is formed by the action of ethyl nitrite and  $HNO_3$  on (3:4:1)-nitro-amido-β-phenyl-propionic acid. It forms short colourless needles which explode feebly on heating. Heated with alcohol it gives *m*-nitro-hydrocinnamic acid (Gabriel, *B.* 15, 845).

**Diazo-nitroso-methyl-nitro-benzene v. DIAZO-NITRO-BENZALDOXIM.**

**p-Diazo-nitroso-oxindole chloride**

$C_8H_7N_2O_2Cl$  or  $C_8H_7(N:N.Cl) \begin{smallmatrix} \text{C}(N.OH) \\ NH \end{smallmatrix} > CO$ .

**p-Diazo-dioxindole-oxim chloride.** Small yellow needles. Prepared by the action of amyl nitrite on a solution of amido-oxindole in HCl. Is only slightly attacked by boiling alcohol (Gabriel a. R. Meyer, *B.* 14, 832; *C. C.* 1885, 516).

**o-Diazo-p-nitro-toluene-piperidine**

$C_7H_7N_2O_2$  i.e. [1:4:2]  $C_6H_4Me(NO_2).N_2.NC_4H_9$  [51°]. From *p*-nitro-*o*-toluidine [107°] by diazotisation of its hydrochloride and subsequent addition of piperidine (Wallach, *A.* 235, 248).

**o-Diazo-nitro-toluene p-sulphonie acid**

$C_6H_4Me(NO_2) \begin{smallmatrix} \text{N}_2 \\ \text{SO}_3 \end{smallmatrix}$ . Formed by dissolving *o*-toluidine *p*-sulphonie acid in fuming  $HNO_3$  and ppg. with ice-water (Eldayduck, *A.* 172, 117). Boiling alcohol under 1160 mm. pressure does not attack it.

**p-Diazo-nitro-toluene o-sulphonie acid.**

Formed by dissolving *p*-toluidine *o*-sulphonie acid in cold fuming  $HNO_3$  (Weckwarth, *A.* 172, 202). Large dark-red prisms. Alcohol heated with it under 1,000 mm. pressure gives nitro-toluene sulphonie acid (Fagel, *A.* 176, 304).

**p-Diazo-nitro-toluene m-sulphonie acid**

$C_6H_4Me(NO_2).N_2.SO_3$  [1:2:4:5]. Formed by dissolving *p*-toluidine *m*-sulphonie acid in fuming  $HNO_3$  (Pechmann, *A.* 173, 214), and also from  $C_6H_4Me(NO_2)(NH_2)SO_3H$  [1:2:4:5] and nitrous

acid, benzol, and water; on boiling with water only  $\frac{1}{2}$  of the theoretical quantity of nitrogen comes off; when boiled with  $\text{FeCl}_3$  all comes off. Boiling alcohol does not affect it, but in a sealed tube at  $100^\circ$  it is converted into *o*-nitro-toluene *m*-sulphonic acid.

***p*-Diazo-di-nitro-toluene *o*-sulphonic acid**  
 $\text{C}_6\text{HMe}(\text{NO}_2)_2 \langle \text{SO}_3 \rangle$ . From *p*-toluidine *o*-sulphonic acid and fuming  $\text{HNO}_3$  (Pagel, A. 176, 806). Yellowish needles. Not affected by alcohol boiling under 1,000 mm. pressure.

**Diazo-oxy-acrylic ether (?)**  
 $\text{C}_6\text{H}_5\text{N}_2\text{O}$ , i.e.  $\text{CN}_2\text{C}(\text{OH})\text{CO}_2\text{Et}$  (?). (142°) at 717 mm. V.D. = 5.0 (obs.). Yellow oil of strong peculiar odour. Volatile with steam.

**Formation.**—Gelatin, swollen with water, is warmed with absolute alcohol whilst  $\text{HCl}$  gas is passed in, it soon dissolves and after distilling off the alcohol a thick brown syrup is left; this latter, which appears to be the hydrochloride of amido-oxy-acrylic ether  $\text{CH}(\text{NH}_2)\text{C}(\text{OH})\text{CO}_2\text{Et}$  yields the diazo-ether when its concentrated aqueous solution is treated with  $\text{NaNO}_2$ ; it is purified by distillation with steam; the yield is 150 grms. from 400 grms. of gelatine.

**Reactions.**—Acids eliminate its nitrogen, but it is very stable towards alkalis, with the exception of  $\text{NH}_3$ , which even in the cold soon splits off  $\text{CO}_2$  and alcohol. By zinc-dust and acetic acid it is reduced first to a hydrazine and finally to an amido-acid. An ethereal solution of iodine converts it into di-iodo-oxy-acrylic ether  $\text{Cl}_2\text{C}(\text{OI})\text{CO}_2\text{Et}$  which on treatment with cold aqueous  $\text{NH}_3$  loses  $\text{CO}_2$  and alcohol and yields di-iodo-vinyl-amine  $\text{Cl}_2\text{CH}(\text{NH}_2)$ . It reduces  $\text{AgNO}_3$  in the cold (Buchner a. Curtius, B. 19, 850).

#### Diazo-o-oxy-benzoic acid

**Diazo-salicylic acid.** Formed by passing  $\text{N}_2\text{O}$  into an aqueous or alcoholic solution of hydrochloride of amido-salicylic acid and concentrating. Crystallised from water (Schmitt, J. 1864, 384; Goldberg, J. pr. [2] 19, 362; F. F. Frankland, O. J. 37, 749). Slender needles.

**Reactions.**—1. Boiled with conc.  $\text{HI}$  it gives iodo-salicylic acid [ $196^\circ$ ] (q. v.). 2. *Mercaptan* at  $170^\circ$  gives salicylic acid (Schmitt a. Mittenzwey, J. pr. [2] 18, 193).

**Chloride.**— $\text{C}_6\text{H}_4(\text{CO}_2\text{H})(\text{OH})\text{N}_2\text{Cl}$ . — **Platino-chloride**  $[\text{C}_6\text{H}_4(\text{CO}_2\text{H})(\text{OH})\text{N}_2\text{Cl}]_2\text{PtCl}_2$ .

**Diazo-*p*-oxy-benzo-amido-oxy-benzoic acid.**  
**Dimethyl derivative.**

**Diazo-amido-anisic acid**  
 $\text{C}_6\text{H}_3(\text{OMe})(\text{CO}_2\text{H})\text{N}_2\text{NH}_2\text{C}_6\text{H}_3(\text{OMe})(\text{CO}_2\text{H})$ . Formed by passing nitrous acid gas into a gold alcoholic solution of amido-anisic acid (Griess, A. 113, 337; 117, 45). Amorphous powder, insol. water, alcohol, and ether. Warm conc.  $\text{HCl}$  converts it into a red acid  $\text{C}_6\text{H}_3\text{O}_2$ . —  $\text{Na}^+\text{A}^{11}\text{aq.} - \text{K}^+\text{A}^{12}\text{aq.} - \text{Et}_4\text{A}^{13}$ : narrow leaflets.

**Diazo-oxy-cinnamic acid. Methyl derivative**  
 $\text{C}_6\text{H}_4(\text{N}_2\text{OH})(\text{OMe})\text{CH}:\text{CH}:\text{CO}_2\text{H}$  [5:2:1]. Formed by diazotising methoxy-amido-cinnamic acid. The chloride forms yellow crystals, which decompose at about  $102^\circ$ . The nitrate  $\text{C}_6\text{H}_4(\text{N}_2\text{NO}_2)(\text{OMe})(\text{CH}_2\text{CO}_2\text{H})$  crystallises in yellow needles, which explode at  $152^\circ$ , nearly

insoluble in acid water, alcohol, and ether (Schnell, B. 17, 1898).

***o*-Diazo-phenol. Chloride**  $\text{C}_6\text{H}_4(\text{OH})\text{N}_2\text{Cl}$ . By passing  $\text{N}_2\text{O}$  into an alcoholic solution of the hydrochloride of *o*-amido-phenol, and then adding ether (Schmitt, B. 1, 67; Böhmer, J. pr. 132, 460). Rhombohedra. Bromine-water added to its aqueous solution forms a yellow pp. of diazo-dibromo-phenol (q. v.).

**Sulphite**  $\text{C}_6\text{H}_4(\text{OH})\text{N}_2\text{SO}_3\text{K aq.}$  Golden scales, got by adding  $\text{KHSO}_3$  to  $\text{C}_6\text{H}_4(\text{OH})\text{N}_2\text{Cl}$  (Schmitt a. Glutz, B. 2, 51; Reisenegger, A. 221, 314).

**Platinochloride**  $[\text{C}_6\text{H}_4(\text{OH})\text{N}_2\text{Cl}]_2\text{PtCl}_2$ . — ***m*-Diazo-phenol. Ethyl derivative** (Wagner, J. pr. [2] 32, 70).

***p*-Diazo-phenol. Nitrate**  $\text{C}_6\text{H}_4(\text{OH})\text{N}_2\text{NO}_3$ . Formed by passing nitrous acid gas into a cold ethereal solution of phenol (Weselsky, Sitz. B. 1875, 9; B. 8, 895), or of *p*-nitroso-phenol (Jäger, B. 8, 814).

**Preparation.**—By passing  $\text{N}_2\text{O}$  into alcoholic solution of hydrochloride of *p*-amido-phenol, adding strong  $\text{HNO}_3$  and cooling strongly (Böhmer, J. pr. 132, 450).

**Reactions.**—1. By warming with dilute  $\text{HBr}$  (15 per cent. solution) it does not give off nitrogen, as diazo-benzene nitrate would do, but forms di-azo-di-bromo-benzene in accordance with the equation:

**Chloride**  $\text{C}_6\text{H}_4(\text{OH})\text{N}_2\text{Cl}$ . Formed by diazotising *p*-amido-phenol hydrochloride. Converted into hydroquinone by boiling conc.  $\text{HCl}$  or dilute  $\text{H}_2\text{SO}_4$  (Schuler, B. 9, 1160). Heated with mercaptan it gives phenol and  $(\text{C}_6\text{H}_5)_2\text{S}_2$  (Schmitt a. Mittenzwey, J. pr. [2] 18, 194). —  $(\text{C}_6\text{H}_4(\text{OH})\text{N}_2\text{Cl})_2\text{PtCl}_2$ .

**Bromide**  $\text{C}_6\text{H}_4(\text{OH})\text{N}_2\text{Br}$ . Formed by passing  $\text{N}_2\text{O}$  into an alcoholic solution of the hydrobromide of *p*-amido-phenol (C. Böhmer, J. pr. 132, 451). Precipitated by ether.

**Platinobromide**  $(\text{C}_6\text{H}_4(\text{OH})\text{N}_2\text{Br})_2\text{PtBr}_2$ . Needles grouped in spherical segments. Got by adding an aqueous solution of  $\text{PtBr}_2$  (prepared like  $\text{PtCl}_2$  by dissolving spongy platinum in  $\text{HBr}$  mixed with  $\text{HNO}_3$  and evaporating) to one of diazo-phenol hydrobromide. If left for several days in contact with their mother liquor, the crystals absorb eight molecules of water of crystallisation changing to blood-red twin crystals resembling gypsum. These are insoluble in ether,  $\text{CS}_2$ , and  $\text{CHCl}_3$ , difficultly soluble in water. The salt heated with 10 pts. of  $\text{Na}_2\text{CO}_3$  does not yield bromophenol.

**Sulphate**  $\text{C}_6\text{H}_4(\text{OH})\text{N}_2\text{SO}_4\text{H}$ . Obtained by adding dilute  $\text{H}_2\text{SO}_4$  to an alcoholic solution of the hydrochloride of *p*-amido-phenol, passing in  $\text{N}_2\text{O}$  and adding ether. Needles. Does not explode when heated. Converted by boiling  $\text{HBr}$  into the bromo-phenyl ether of hydroquinone (q. v.).

**Sulphite**  $\text{HO}(\text{C}_6\text{H}_4\text{N}_2\text{SO}_3\text{K})$ . From *p*-amido-phenol,  $\text{HCl}$ ,  $\text{NaNO}_2$ , and  $\text{K}_2\text{SO}_3$  (Reisenegger, A. 221, 316). Yellowish plates.

**Ethyl derivative**  $\text{C}_6\text{H}_4(\text{OEt})\text{N}_2\text{OH}$ . **Salts.**— $\text{C}_6\text{H}_4(\text{OEt})\text{N}_2\text{Cl}$ . From *p*-amido-phenol hydrochloride by solution in alcohol and treatment with  $\text{N}_2\text{O}$ . Precipitated by ether as an oil.

Crystallises when cooled to  $-18^{\circ}$ . But if  $\text{H}_2\text{SO}_4$  be added to the alcoholic solution of the chloride, avoiding rise of temperature, crystals of the sulphate  $\text{C}_6\text{H}_4(\text{OEt})\text{N}_2\text{SO}_4\text{H}$  separate. Boiled with water this forms  $\text{C}_6\text{H}_4(\text{OEt})(\text{OH})$ , hydroquinone mono ethylic ether (q. v.) (Hantzsch, *J. pr.* 130, 461).

**Methyl derivative.** The salts are formed by diazotising *p*-anisidine (Salkowski, *B.* 7, 1009):  $\text{C}_6\text{H}_4(\text{OMe})\text{N}_2\text{NO}_3$ ,  $\text{C}_6\text{H}_4(\text{OMe})\text{N}_2\text{SO}_4\text{H}$ .

**Diazo-phenol-carbamic ether.** *Ethyl derivative*

**Preparation.**—By passing  $\text{N}_2\text{O}_5$  into a solution of the hydrochloride of ethoxy-amido-phenyl-urethane,  $\text{C}_6\text{H}_4(\text{OEt})(\text{NH}_2)\text{NH.CO.Et}$ ,  $\text{HCl}$  (Köhler, *J. pr.* [2] 29, 273).

**Properties.**—Slender, silvery-white matted needles. Insol. water, sol. alcohol, ether, and glacial acetic acid. Decomposes below  $100^{\circ}$ .

**Reactions.** 1. Does not explode. 2. Not affected by boiling alcohol. 3. Boiled with soda, it is decomposed with evolution of nitrogen.

**Diazo-phenol sulphonic acids**  
 $\text{C}_6\text{H}_3(\text{N}_2\text{O})(\text{OH})(\text{SO}_3\text{H})$  [1:1:3] and [3:1:1] are unstable crystalline acids obtained by diazotising the corresponding amido-phenol sulphonic acids (Beimewitz, *J. pr.* [2] 8, 62).

**Diazo phenol disulphonic acid**

$\text{C}_6\text{H}_3(\text{SO}_3\text{H}) \begin{array}{c} \diagup \text{N}_2 \diagdown \\ \diagdown \text{O} \diagup \end{array}$ . From *p*-amido-phenol disulphonic acid (q. v.) (Wilsing, *A.* 215, 238).

**Salt.**  $\text{K}_2\text{A}^{\text{aq}}$ . Small sulphur-yellow needles. Warmed with water it forms hydroquinone disulphonic acid.

***p*-p-Tetra-azo-diphenyl**

**Nitrate**  $\text{NO}_2\text{N}_2\text{C}_6\text{H}_4\text{C}_6\text{H}_4\text{N}_2\text{NO}_2^{\text{aq}}$ . Formed by passing nitrous acid gas into an alcoholic solution of nitrate of benzidine, and ppg. with ether (Griess, *Tr.* 1864, iii. 719). White needles, v. sol. water, m. sol. alcohol, insol. ether. Explodes when heated. Boiling water forms *p*-*p*-di-oxy-diphenyl.

**Perbromide**  $\text{Br}_2\text{N}_2\text{C}_6\text{H}_4\text{C}_6\text{H}_4\text{N}_2\text{Br}_2$ .

**Imide**  $\text{N}_2\text{C}_6\text{H}_4\text{C}_6\text{H}_4\text{N}_2$  [127]. White plates.

**Platinochloride**

$(\text{ClN}_2\text{C}_6\text{H}_4\text{C}_6\text{H}_4\text{N}_2)\text{PtCl}_4$ ; yellow plates.

**Sulphate**

$(\text{HSO}_3\text{N}_2\text{C}_6\text{H}_4\text{C}_6\text{H}_4\text{N}_2\text{SO}_3\text{H})_2\text{H}_2\text{SO}_4$ ; white needles.

**Anilide**  $\text{PhNH.N}_2\text{C}_6\text{H}_4\text{C}_6\text{H}_4\text{N}_2\text{NHPh}$ : large-shaped crystals, insol. water. Explosive.

**Piperidine**

$\text{C}_6\text{H}_4\text{N}_2\text{N}_2\text{C}_6\text{H}_4\text{C}_6\text{H}_4\text{N}_2\text{NC}_6\text{H}_5$ . From benzidine by diazotisation and treatment with piperidine. Insol. water, sl. sol. alcohol, v. sol. ether (Wallach, *A.* 235, 271).

***m*-*m*-Tetra-azo-diphenyl** (Brunner a. Witt, *B.* 20, 1028).

**Diazo-phenyl-carbamic ether**

$\text{C}_6\text{H}_5 \begin{array}{c} \diagup \text{N} \diagdown \\ \diagdown \text{N} \diagup \end{array} \text{CO.Et}$ . Formed by diazotising *o*-amido-phenyl-carbamic ether (Rudolph, *B.* 12, 1296).

**Hexa-azo-tri-phenyl-carbinol**

**Chloride**  $[\text{C}_6\text{H}_4(\text{N}_2\text{Cl})_3]\text{COH}$ . **Diazo-*p*-rosaniline chloride.** Formed by diazotising *p*-

rosaniline hydrochloride (*B.* a. O. Fischer, *A.* 194, 274).— $\text{C}_6\text{H}_4\text{N}_2\text{Cl}_3\text{AuCl}_4$ .

**Hexa-azo-tri-phenyl-carbinyl cyanide**

**Chloride**  $[\text{C}_6\text{H}_4(\text{N}_2\text{Cl})_3]\text{C.CN}$  2aq. From hydrocyano-*p*-rosaniline hydrochloride by diazotisation. Slender needles, v. sol. water. Gives, with boiling water,  $(\text{C}_6\text{H}_4\text{OH})_3\text{C.CN}$  (Fischer, *A.* 194, 275).

**Hexa-azo-tri-phenyl-methane chloride**

$(\text{C}_6\text{H}_4\text{N}_2\text{Cl})_3\text{CH}$ . **Diazo-*p*-leucaniline.** Formed by diazotising tri-amido-tri-phenyl-methane hydrochloride (E. a. O. Fischer, *A.* 194, 269). Gives *p*-rosolic acid (aurin) when boiled with water.

**Di-azo-phenyl methyl ketone sulphite of sodium**  $\text{CH}_3\text{CO.C}_6\text{H}_4\text{N}_2\text{SO}_3\text{K}$ . Formed by diazotising *o*-amido-acetophenone and treating the product with  $\text{K}_2\text{SO}_3$ . On reduction it gives the hydrazine salt:  $\text{CH}_3\text{CO.C}_6\text{H}_4\text{NH.NHSO}_3\text{K}$  whence  $\text{HCl}$  forms methyl-indazol,

$\text{C}_6\text{H}_5 \begin{array}{c} \diagup \text{CMe} \diagdown \\ \diagdown \text{N}-\text{NH} \diagup \end{array}$  (v. INDAZOL). The aqueous solution of the hydrazine salt changes to

$\text{C}_6\text{H}_5 \begin{array}{c} \diagup \text{CMe} \diagdown \\ \diagdown \text{N}-\text{N.SO}_3\text{Na} \diagup \end{array}$  methyl-indazol sulphonate of sodium (Fischer a. Tafel, *A.* 227, 305).

**Hexa-azo-di-phenyl-tolyl-carbinol.**

**Chloride**  $(\text{C}_6\text{H}_4\text{N}_2\text{Cl})_2\text{C}(\text{OH}).\text{C}_6\text{H}_4\text{MeN}_2\text{Cl}$ . **Diazo-rosaniline.** Formed by diazotising rosaniline hydrochloride (Caro a. Wanklyn, *Z.* 1866, 511; E. a. O. Fischer, *A.* 194, 279). Gives rise to rosolic acid when boiled with water.— $(\text{C}_6\text{H}_4\text{N}_2\text{Cl})_2.3\text{PtCl}_4.6\text{aq.} - \text{C}_6\text{H}_4\text{N}_2\text{Cl}_3\text{AuCl}_4$ .

**Hexa-azo-di-phenyl-tolyl-carbinyl cyanide.** **Chloride**  $(\text{C}_6\text{H}_4\text{N}_2\text{Cl})_2\text{C}(\text{CN}).\text{C}_6\text{H}_4\text{MeN}_2\text{Cl}$ . **Diazo-hydrocyan-rosaniline.**—Gold salt.— $\text{C}_6\text{H}_4(\text{CN})\text{N}_2\text{Cl}_3\text{AuCl}_4$ .

**Diazo-resorcin chloride.** **Diethyl ether**  $\text{C}_6\text{H}_3(\text{OEt})_2\text{N}_2\text{Cl}$ . From the amido-compound (Pukall, *B.* 20, 1136). Unstable crystals.

**Diazo-rosaniline** (v. *supra*).

**Diazo-salicylic acid** v. DIAZO-OXY-BENZOIC ACID.

**Diazo-succinamic acid**

$\text{CO}_2\text{H.CH}_2\text{CN}_2\text{CONH}_2$ .

**Methyl ether**  $\text{A}^{\text{Me}}$ :  $[84^{\circ}]$ ; long yellow prisms (from alcohol). Formed by the action of aqueous  $\text{NH}_3$  upon methyl diazo-succinate. By decomposition with cold slightly acidified water it yields methyl fumarate and methyl malamate. Heated with benzoic acid at  $140^{\circ}$ – $150^{\circ}$  it gives methyl benzoyl-malamate. Iodine in ethereal solution converts it into methyl di-iodo-succinamate— $\text{CO}_2\text{Me.CH}_2\text{Cl}_2\text{CONH}_2$  (Curtius a. Koch, *B.* 19, 2466).

**Ethyl ether**  $\text{C}_2\text{H}_5\text{N}_2\text{CONH}_2(\text{CO}_2\text{Et})$ — $[112^{\circ}]$ ; long thin yellow prisms; easily soluble in hot water and alcohol, sparingly in cold water and ether. It is not altered by boiling with pure water, but by acids and alkalis is at once decomposed with evolution of nitrogen. Reduced to aspartic ether by zinc-dust and acetic acid (Curtius a. Koch, *B.* 18, 1293).

**Diazo-succinic acid**  $\text{C}_2\text{H}_2\text{N}_2(\text{CO}_2\text{H})_2$ . The di-methyl and di-ethyl ethers of this acid are obtained by mixing iced solutions of the hydrochlorides of the aspartic ethers  $\text{CO}_2\text{R.CH}(\text{NH}_2\text{Cl}).\text{CH}_2\text{CO}_2\text{R}$  and sodium nitrite, and adding a few drops of dilute  $\text{H}_2\text{SO}_4$  after

when the product is shaken out with ether. The ethers form dark-yellow oils which have not yet been obtained in a pure state. By boiling with water or aqueous acids they are decomposed with evolution of nitrogen and formation of the corresponding fumaric ether. They decompose spontaneously on keeping, evolving nitrogen and forming azinsuccinic ethers  $(\text{CO}_2\text{R})_2\text{C}_2\text{H}_2\text{N}_2\text{N}:\text{C}_2\text{H}_4(\text{CO}_2\text{R})_2$ . Strong aqueous  $\text{NH}_3$  converts them into diazo-succinamic ethers.

*p*-DIAZO-TOLUENE.

**Salts.**—The preparation and properties of these salts resemble those of the corresponding diazo-benzene salts (Griess, *C. J.* 20, 86).— $\text{C}_6\text{H}_4\text{Me.N}_2\text{NO}_2$ : long slender white needles.— $(\text{C}_6\text{H}_4\text{Me.N}_2\text{Cl})\text{PtCl}_5$ : yellow prismatic crystals.  $\text{C}_6\text{H}_4\text{Me.N}_2\text{SO}_3\text{H}$ .— $\text{C}_6\text{H}_4\text{Me.N}_2\text{Hr}$ .

**Dicyanide**  $\text{C}_6\text{H}_4\text{N}_4$  or  $\text{C}_6\text{H}_4\text{Me.N}_2\text{CN.HCN}$ . [78°]. Needles or leaflets. Formed by the action of a diazo-toluene salt on a solution of KCN (*Z.* 42, 1638).

**Anilide**  $\text{C}_6\text{H}_4\text{Me.N}_2\text{NHPh}$  or, alternatively,  $\text{Ph.N}_2\text{NH.C}_6\text{H}_4\text{Me}$ . From *p*-toluidine and diazobenzene nitrate or from aniline and *p*-diazotoluene nitrate (Griess, *A.* 137, 60; *B.* 7, 1619). Narrow yellow leaflets. By warming with phenol it gives a mixture of aniline, *p*-toluidine, benzene-azo-phenol and *p*-toluene-azo-phenol; similarly with resorcin (Heumann a. Oeconomides, *B.* 20, 907).

***p*-Chloro-anilide**. Formed from *p*-chloro-diazo-benzene and *p*-toluidine. By heating with phenol it gives *p*-toluene-azo-phenol and *p*-chloraniline (Heumann a. Oeconomides, *B.* 20, 909).

**Piperidine**  $\text{C}_6\text{H}_4\text{N}_2$ , i.e.  $\text{C}_6\text{H}_4\text{N}_2\text{NC}_4\text{H}_9$ . [41°]. From  $\text{CH}_3\text{C}_6\text{H}_4\text{N}_2\text{Cl}$  and piperidine. Prisms (from alcohol or ether). Insol. water. Dry HCl passed into its solution in petroleum-ether appears to form an unstable hydrochloride, quickly decomposing into diazotoluene chloride and piperidine hydrochloride (Wallach, *A.* 235, 244).

***p*-Toluide**  $\text{C}_6\text{H}_4\text{Me.N}_2\text{NH.C}_6\text{H}_4\text{Me}$ . [116°]. Formed by passing nitrous acid gas into a solution of *p*-toluidine in alcohol and ether (Griess, *A.* 121, 277; when pure (by digestion with alcoholic  $(\text{NH}_4)_2\text{S}$ ) it forms nearly colourless large thin prisms (Bernthsen a. Goske, *B.* 20, 928).

***p*-Ethyl-toluide**  $\text{C}_6\text{H}_4\text{Me.N}_2\text{NEt.C}_6\text{H}_4\text{Me}$ . Decomposed by acids into ethyl-*p*-toluidine and *p*-diazotoluene chloride (Gastiger, *Bh.* [2] 42, 342).

*o*-DIAZO-TOLUENE-*o*-TOLUIDE

[2:1]  $\text{C}_6\text{H}_3\text{Me.N}_2\text{NH.C}_6\text{H}_3\text{Me}$  [1:2]. [51°]. Orange-yellow powder of microscopic needles. Prepared by adding sodium nitrite (1 mol.) to an aqueous solution of *o*-toluidine (2 mols.) and HCl (3 mols.) and then neutralising the HCl with sodium acetate, the temperature being kept below -5° during the whole reaction. It is crystallised by dissolving in cold alcohol and adding ice (Fischer a. Wimmer, *B.* 20, 1582).

*o*-DIAZO-TOLUENE-AZO-TOLUENE  $\text{C}_6\text{H}_3\text{N}_4\text{OH}$  i.e.

$\text{C}_6\text{H}_3\text{N}_4\text{OH}$  (?) Obtained by diazotising toluene-azo-*o*-toluidine; the salts crystallise out when a stream of nitrous acid gas is passed into an alcoholic solution of toluene-*o*-azo-

toluidine and an excess of acid, or upon subsequent addition of a little ether. On heating with water or alcohol it decomposes, evolving nitrogen like ordinary diazo-compounds. By  $\text{SnCl}_2$  or  $\text{SO}_2$  it is not reduced to a hydrazine but gives a stable compound  $\text{C}_6\text{H}_3\text{N}_4$ , which

probably has the constitution  $\text{C}_6\text{H}_3\text{N}_4$   $\begin{matrix} \text{N}-\text{NH} \\ | \quad | \\ \text{N}-\text{NC}_6\text{H}_3 \end{matrix}$

by bromine this body is reconverted into the diazo-perbromide. By zinc-dust and alcohol it is converted into *m*-toluene-*p*-azo-toluene [58°] with evolution of nitrogen. The diazo-imide loses nitrogen on heating and yields tolyl-

azimido-toluene  $\text{C}_6\text{H}_3\text{N}_2$   $\begin{matrix} \text{N} \\ | \quad | \\ \text{N}-\text{C}_6\text{H}_3 \end{matrix}$  identical with

that obtained by oxidation of toluene-azo-*o*-toluidine. *o*-Diazo-toluene-azo-toluene reacts with amines and phenols like an ordinary diazo-compound; the products, however, reduce to a diamine or amido-phenol and tolyl-azimido-toluene. All the salts have a deep orange-yellow colour and are tolerably stable.  $\text{C}_6\text{H}_3\text{N}_4\text{Cl}^+$ : red granular crystals.— $(\text{C}_6\text{H}_3\text{N}_4\text{Cl})\text{PtCl}_5$ : yellow acicular crystals.— $\text{C}_6\text{H}_3\text{N}_4\text{NO}_2^+$ : slender red pointed crystals.— $\text{C}_6\text{H}_3\text{N}_4\text{SO}_3\text{H}^+$ : red interwoven needles.— $\text{C}_6\text{H}_3\text{N}_4\text{Br}_2$ : [125°], long glistening red needles or compact crystals.

**Imide**  $\text{C}_6\text{H}_3\text{N}_4$ : [85°], thick yellowish red crystals; formed by the action of alcoholic  $\text{NH}_3$  upon the perbromide (Zincke a. Lawson, *B.* 19, 1452).

*Product of Reduction*  $\text{C}_6\text{H}_3\text{N}_4$ , probably

$\text{C}_6\text{H}_3\text{N}_4$   $\begin{matrix} \text{N}-\text{NH} \\ | \quad | \\ \text{N}-\text{NC}_6\text{H}_3 \end{matrix}$  [168°]. Long colourless

needles. V. sol. hot alcohol, sl. sol. ether and chloroform, insol. water. It has no basic properties. It is not affected by reducing agents. Bromine in alcoholic or acetic acid solution readily converts it into *o*-diazotoluene-azo-toluene perbromide. On addition of  $\text{Ag}_2\text{O}$  to its alcoholic solution nitrogen is evolved and *m*-*p*-azotoluene [58°] is formed.

**Acetyl derivative**  $\text{C}_6\text{H}_3\text{N}_4\text{Ac}$  [134°]: glistening white plates (Zincke a. Lawson, *B.* 19, 1457).

*p*-DIAZO-TOLUENE-AZO-TOLUENE

[2:1]  $\text{C}_6\text{H}_4(\text{CH}_3)-\text{N}_2-\text{C}_6\text{H}_4(\text{CH}_3)\text{N}_2\text{OH}$  [1:3:4]. Prepared by dissolving toluene-azo-*p*-toluidine in alcohol, adding an excess of HCl, diazotising by passing  $\text{N}_2\text{O}_5$  into the well-cooled solution, and precipitating the diazo-salt with ether. By reduction with  $\text{SnCl}_2$  or zinc-dust and acetic acid in cold dilute aqueous solution it is split up (without formation of a hydrazine) into *o*-toluidine and tolylene-*p*-diamine.

**Salts.**— $\text{C}_6\text{H}_4\text{N}_2\text{N}(\text{C}_6\text{H}_4\text{N}_2)$ : slender brownish-yellow needles, m. sol. water and alcohol.— $\text{C}_6\text{H}_4\text{N}_2\text{Br}_2$ : yellow crystalline pp. which changes on standing to small violet needles.— $\text{C}_6\text{H}_4\text{N}_2\text{SO}_3\text{Na}$ : glistening scales (from alcohol), v. sol. hot alcohol, sl. sol. water.

**Imide**  $\text{C}_6\text{H}_4\text{N}_2$ : [60°]; long plates; sol. alcohol and acetic acid (Zincke a. Lawson, *B.* 20, 1181).

*o*-DIAZO-TOLUENE *m*-SULPHONIC ACID

$\text{MeC}_6\text{H}_3\text{N}_2\text{SO}_3$  [2°]. Precipitated as a white powder when nitrous gas is passed into a

cold solution of *o*-toluidine sulphonic acid. Explodes feebly at 100° (Neville a. Winther, *C. J.* 37, 628).

***o*-Diazo-toluene *p*-sulphonic acid.**

Minute monoclinic prisms (Hayduck, *A.* 172, 213; 174, 341). Boiling alcohol produces  $\text{MeC}_6\text{H}_4(\text{OEt})\cdot\text{SO}_3\text{H}$  [1:2:4].

***p*-Diazo-toluene *o*-sulphonic acid.** Yellow or brown needles (Ascher, *A.* 161, 8; Jensen, *A.* 172, 235). Heated with alcohol under pressure it gives  $\text{MeC}_6\text{H}_4(\text{OEt})(\text{SO}_3\text{H})$  Remsen a. Palmer, *Am.* 8, 243).

***p*-Diazo-toluene *m*-sulphonic acid**

$\text{MeC}_6\text{H}_4\langle\text{SO}_3\text{H}\rangle\left[\frac{\text{N}_2}{\text{SO}_3}\right]$ . More soluble than the corresponding *o*-compound (Neville a. Winther, *C. J.* 37, 631). Prepared by passing nitrous acid gas into *p*-toluidine sulphonic acid suspended in alcohol. Hot alcohol gives toluene *m*-sulphonic acid (Petermann, *A.* 173, 201).

***p*-Diazo-toluene *exo*-sulphonic acid**

$\text{C}_6\text{H}_4\langle\text{CH}_3\rangle\text{SO}_3\text{H}$ . Heated with alcohol under 1,100 mm. pressure it gives  $\text{C}_6\text{H}_4(\text{OEt})\cdot\text{CH}_3\cdot\text{SO}_3\text{H}$  (Mohr, *A.* 221, 219).

***p*-Diazo-toluene-*sulphonic-amido*-toluene sulphonic acid. Amide**  
[1:2:2]  $\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)\text{N}_2\cdot\text{NH}_2\text{C}_6\text{H}_4\text{Me}\cdot\text{SO}_3\text{NH}_2$  [2:1:1]. From  $\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)\text{SO}_3\text{NH}_2$  [1:2:1], alcohol, and nitrous acid gas (Paysan, *A.* 221, 211). Decomposed by HCl into  $\text{N}_2$ ,  $\text{C}_6\text{H}_4\text{ClMe}\cdot\text{SO}_3\text{NH}_2$ , and  $\text{C}_6\text{H}_4(\text{NH}_2)\text{Me}\cdot\text{SO}_3\text{NH}_2$ .

***o*-Diazo-toluene disulphonic acid**

$\text{C}_6\text{H}_3\text{Me}(\text{SO}_3\text{H})\langle\text{SO}_3\text{H}\rangle\left[\frac{\text{N}_2}{\text{SO}_3}\right]$  [1:2:2]. From  $\text{N}_2\text{O}_5$  and aqueous *o*-toluidine disulphonic acid at 0° (Limpriecht, *B.* 18, 2176; Husse, *A.* 230, 291). Microscopic needles. Explosive. Heated with alcohol under pressure it gives  $\text{C}_6\text{H}_3\text{Me}(\text{OEt})(\text{SO}_3\text{H})_2$ . With HI it forms  $\text{C}_6\text{H}_3\text{MeI}(\text{SO}_3\text{H})_2$ .

Salts.— $\text{KA}'$ ,— $\text{BaA}'$ , aq.,— $\text{PbA}'$ .

***p*-Diazo-toluene di-sulphonic acid**

$\text{C}_6\text{H}_3\text{Me}(\text{SO}_3\text{H})\langle\text{SO}_3\text{H}\rangle\left[\frac{\text{N}_2}{\text{SO}_3}\right]$ . Formed by diazotisation of *p*-toluidine-di-sulphonic acid. Yellowish crystals. By heating with HI it yields *p*-iodo-toluene-di-sulphonic acid; with HBr it yields *p*-bromo-toluene-di-sulphonic acid.

Salts.— $\text{AK}$ : large yellow prisms.— $\text{A}'\text{Ba}$ : yellowish white needles.— $\text{A}'\text{Pb}$ : small red prisms (Limpriecht, *B.* 18, 2178).

***o*-Diazo-toluene-amido-toluic acid**

$\text{C}_6\text{H}_3\text{Me}(\text{CO}_2\text{H})\text{N}_2\cdot\text{NH}_2\text{C}_6\text{H}_4\text{Me}\cdot\text{CO}_2\text{H}$ . From amido-toluic acid and nitrous ether (Griess, *A.* 117, 59). Minute yellow prisms (containing  $\frac{1}{2}$  aq); insol. water, alcohol, and ether.

***o*-Diazo-*p*-toluidine bromide.**

**Acetyl derivative**

$\text{C}_6\text{H}_3\text{Me}(\text{NHAc})\text{N}_2\text{Br}$  [1:2:2]. From  $\text{C}_6\text{H}_3\text{Me}(\text{NHAc})(\text{NH}_2)$  [1:1:2], conc. HBr and conc.  $\text{NaNO}_2$  at 0° (Wallach, *A.* 235, 249).

Reactions.—1. Hot  $\text{Ac}_2\text{O}$  converts it into  $\text{C}_6\text{H}_3\text{Me}(\text{NHAc})(\text{OAc})$  [1:2:5].—2. Nitro-ethane and  $\text{NaOEt}$  give  $\text{C}_6\text{H}_3\text{Me}(\text{NHAc})\cdot\text{N}_2\cdot\text{CHMe}(\text{NO}_2)$  [1:4:2].—3. HNEt gives  $\text{C}_6\text{H}_3\text{Me}(\text{NHAc})\text{N}_2\cdot\text{NEt}$  [1:4:2].—4. Piperidine gives the piperidide:  $\text{C}_6\text{H}_3\text{Me}(\text{NHAc})\text{N}_2\cdot\text{NC}_5\text{H}_{10}$  [1:4:2]. HCl passed into an alcoholic solution of this base gives a

pp. of  $\text{C}_6\text{H}_3\text{Me}(\text{NHAc})\text{N}_2\cdot\text{NEt}$  gives  $\text{C}_6\text{H}_3\text{Me}(\text{NHAc})\text{OL}$ .

**Diazo-*m*-xylene-sulphonic acid**

$\text{C}_6\text{H}_3\text{Me}_2\langle\text{SO}_3\text{H}\rangle\left[\frac{\text{N}_2}{\text{SO}_3}\right]$  [1:3:4:6]. White pp. Sparingly soluble in water. Decomposes at 60°–70°. Combines with phenols and amines. Formed by diazotisation of *m*-xylylene-sulphonic acid (Nölting a. Kohn, *B.* 19, 138).

**Diazo-*p*-xylene-sulphonic acid**

$\text{C}_6\text{H}_3\text{Me}_2\langle\text{SO}_3\text{H}\rangle\left[\frac{\text{N}_2}{\text{SO}_3}\right]$  [1:4:2]. Yellowish white plates. Stable at ordinary temperature, decomposes on heating with water at 60°–70°. Formed by the diazotisation of *p*-xylylene-sulphonic acid  $\text{C}_6\text{H}_3\text{Me}_2(\text{NH}_2)(\text{SO}_3\text{H})$  [1:4:2:5] (Nölting a. Kohn, *B.* 19, 141).

**DISAZO-COMPOUNDS.** *Secondary azo-compounds.* Compounds containing two azo-groups of the form  $\text{C}-\text{N}_2-\text{C}$ . The general methods by which they may be prepared are given in the article on azo-colouring matters (*p.* 368). The nomenclature here used is like that used for azo-compounds. To find the name of a disazo-compound, write down the formula, strike out everything between the two  $\text{N}_2$  groups, remove one of the  $\text{N}_2$  groups, and join the remaining parts of the formula together and name the resulting azo-compound as directed on *p.* 369. Then insert after the word 'azo' the name of the central hydrocarbon, preceded by prefixes representing its substituents and followed by 'azo.'

**Di-amido-benzene-azo-benzene-azo-benzene sulphonic acid**

[4:1]  $\text{C}_6\text{H}_3(\text{SO}_3\text{H})-\text{N}_2-\text{C}_6\text{H}_4-\text{N}_2-\text{C}_6\text{H}_4(\text{NH}_2)_2$  [1:2:4]. Formed by the combination of diazo-benzene-azo-benzene-*p*-sulphonic acid with *m*-phenylene diamine. Red microscopic needles. V. sl. sol. alcohol and ether. In  $\text{H}_2\text{SO}_4$  it dissolves with a violet-blue colour.— $\text{KA}'$  2aq: red glistening plates, sl. sol. hot, v. sl. sol. cold, water, dyes silk, wool, and cotton a brownish-red (Griess, *B.* 16, 2035).

**Amido-sulpho-naphthalene-azo-diphenyl-azo-naphthylamine sulphonic acid**

[1:4:2]  $\text{C}_{10}\text{H}_7(\text{NH}_2)(\text{SO}_3\text{H})-\text{N}_2-\text{C}_6\text{H}_5$ .

[1:4:2]  $\text{C}_{10}\text{H}_7(\text{NH}_2)(\text{SO}_3\text{H})-\text{N}_2-\text{C}_6\text{H}_5$ . Formed by combining diazotised benzidine with (a)-naphthylamine-*p*-sulphonic acid. Dyes cotton from an alkaline bath scarlet, turned blue by a trace of acid. The aqueous solution is readily reduced by  $\text{NH}_2$  and zinc-dust, giving benzidine and naphthylene-*o*-di-amine sulphonic acid (Witt, *B.* 19, 1719).

**Benzene-azo-*m*-diamido-benzene-azo-benzene**

$\text{C}_6\text{H}_5-\text{N}_2-\text{C}_6\text{H}_3(\text{NH}_2)_2-\text{N}_2-\text{C}_6\text{H}_5$  [2:5:2]. Formed by the combination of diazobenzene with chrysoidine. Dark red needles or six-sided plates. Sol. hot chloroform and benzene, v. sl. sol. alcohol and ether, insol. water. Weak base. Salts.— $\text{B}'\text{HCl}$ : violet-brown amorphous solid.— $\text{B}'\text{H}_2\text{Cl}_2\text{PtCl}_4$ : violet-brown amorphous pp. (Griess, *B.* 16, 2028).

**Benzene-azo-*m*-diamido-benzene-azo-benzene *p*-sulphonic acid**

$\text{C}_6\text{H}_3(\text{SO}_3\text{H})-\text{N}_2-\text{C}_6\text{H}_3(\text{NH}_2)_2-\text{N}_2-\text{C}_6\text{H}_5$ . Formed by the action of *p*-diazo-benzene-sulphonic acid on chrysoidine. Dark-brown microscopic crystals. V. sl. sol. alcohol insol.

ether. A.K.: reddish-brown plates, sol. hot, sl. sol. cold, water (Griess, B. 16, 2032).

**Benzene-azo-di-amido-benzene-azo-benzole acid**  $C_6H_4(O_2H)-N_2-C_6H_4(NH_2)-N_2-C_6H_4$ . Formed by combining *m*-diazobenzic acid with chrysoidine (Griess, B. 16, 2032). Brownish-red powder. Insoluble or nearly insoluble in all ordinary solvents. Soluble in alkalis with a brownish-red colour.

(a)-**Benzene-azo-*m*-di-amido-benzene-azo-toluene**  $C_6H_4-N_2-C_6H_4(NH_2)-N_2-C_6H_4$ . [192°]. Formed together with a small quantity of the (β)-isomeride by the combination of *p*-diazobenzene with *p*-toluene-azo-phenylene-diamine. Dark-red glistening needles. Sol. ether, chloroform and hot benzene, insol. water and alcohol.

(β)-**Benzene-azo-*m*-di-amido-benzene-azo-toluene**  $C_6H_4-N_2-C_6H_4(NH_2)-N_2-C_6H_4$ . [225°]. Slender yellow needles. Sol. alcohol and ether, v. sol. chloroform, sol. in water (Griess, B. 16, 2029).

**Benzene-azo-*m*-di-amido-benzene-*p*-azo-toluene**  $C_6H_4-N_2-C_6H_4(NH_2)-N_2-C_6H_4$ . [214°]. Formed by the combination of *p*-diazobenzene with chrysoidine (Griess, B. 16, 2030). Dark-red glistening needles. Sl. sol. chloroform, ether, and benzene.

**Benzene-azo-benzene-azo-*p*-cresol**

(4)  $C_6H_4-N_2-C_6H_4-N_2-C_6H_4(CH_3)(OH)$ . [160°]. Obtained by the action of diazo-benzene-azo-benzene chloride (by diazotising benzene-azo-aniline) on an alkaline solution of *p*-cresol (Nöling a. Kohn, B. 17, 354). Small brown needles. Sl. sol. alcohol, m. sol. chloroform, benzene, and acetic acid. Dissolves in  $H_2SO_4$  with a reddish violet colour.

**Benzene-azo-benzene-azo-ethyl-(β)-naphthylamine**  $C_6H_4-N_2-C_6H_4-N_2-C_{10}H_7NH_2$ . [142°]. Small red needles. Formed by heating ethyl-(β)-naphthyl-nitrosamine with an acetic acid solution of benzene-azo-aniline (Henriques, B. 17, 2670).

**Benzene-azo-benzene-azo-(β)-naphthol**

$C_6H_4-N_2-C_6H_4-N_2-C_{10}H_7OH$ . From diazotised benzene-azo-aniline and (β)-naphthol (Nietzki, B. 13, 1838). Brick-red powder.

**Benzene-azo-benzene-azo-resorcin**

$C_6H_4-N_2-C_6H_4-N_2-C_6H_4(OH)_2$ . By the action of diazotised benzene-azo-aniline on resorcinol two isomerides are formed which are separated by their different solubilities in aqueous alkalis.

(a)-**Compound** [181°]. Brownish-red powder consisting of microscopic tables. Dissolves with a carmine red colour in aqueous NaOH and in  $H_2SO_4$ . Sol. alcohol, ether, and chloroform.

(β)-**Compound** [215°]. Brown powder. Dissolves in alcoholic NaOH with a violet-blue colour and in  $H_2SO_4$  with a pure blue colour, v. sl. sol. alcohol, ether, and chloroform, insol. aqueous NaOH (Wallach, B. 15, 2817).

**Benzene-azo-methyl-pyrrol-azo-benzene**

$C_6H_4-N_2-C_6H_4NMe-C-N_2-C_6H_4$   
 $C_6H_4-N_2-C-N_2-C_6H_4$   
probably [196°]. Formed by the methylation of benzene-azo-pyrrol-benzene.

Red plates (O. Fischer a. Hepp, B. 19, 2253).

Vol. I.

**Benzene-azo-oxy-benzene-azo-benzene**

(1)  $C_6H_4-N_2-C_6H_4(OH)-N_2-C_6H_4$ . **Benzene-diazo-phenol. Phenol-bi-diazo-benzene**. [181°]. Formed, together with benzene-azo-phenol, by treating diazo-benzene nitrate with BaCO<sub>3</sub> in the cold, or by the action of diazo-benzene nitrate upon a solution of benzene-azo-phenol in KOH aq. (Griess, A. 137, 86; B. 9, 623). Brown lustrous needles or plates (from alcohol). V. sl. sol. water, v. sol. KOH aq., v. sl. sol. NH<sub>4</sub>Aq, insol. Na<sub>2</sub>CO<sub>3</sub> aq.

**Methyl ether**  $C_6H_4-N_2-C_6H_4(OMe)-N_2-C_6H_4$  [110°], small yellow crystals, v. sol. ether, benzene, acetone, and hot alcohol.

**Acetyl derivative**  $C_6H_4-N_2-C_6H_4(N_2OAc)-N_2-C_6H_4$  [116°], small yellow needles, sol. alcohol, ether, and benzene.

**Benzoyl derivative**  $C_6H_4-N_2-C_6H_4(N_2OBz)-N_2-C_6H_4$  [139°], small yellow needles, sl. sol. cold alcohol (Nöling a. Kohn, B. 17, 368).

**Benzene-azo-di-oxy-benzene-azo-benzene**

$C_6H_4-N_2-C_6H_4(OH)_2-N_2-C_6H_4$ . By the action of diazo-benzene chloride on an alkaline solution of benzene-azo-resorcin two isomerides are formed which are separated by their solubility in aqueous alkalis. A third isomeride (γ)-is formed, together with benzene-azo-resorcin, by the action of diazo-benzene chloride on resorcin treated with KOH (1 mol.) in dilute aqueous solution.

(a) **Compound** [215°]. Brown felted needles. Dissolves easily with a red colour in aqueous NaOH and in  $H_2SO_4$ . Sl. sol. alcohol and ether, m. sol. chloroform. Its di-acetyl derivative forms brown glistening needles, [184°] (Wallach).

(β)-**Compound** [220°]. Microscopic needles. Sl. sol. alcohol and chloroform, insol. aqueous NaOH. Dissolves in  $H_2SO_4$  with an indigo-blue colour, and in alcoholic NaOH with a red colour (Wallach, B. 15, 2816).

(γ)-**Compound** [222°]. Large red needles. Sol. chloroform, v. sl. sol. alcohol. It dissolves in strong alkalis with a brownish-yellow colour; in  $H_2SO_4$  with the same colour. By tin and HCl it is reduced to aniline and di-amido-resorcin.

**Di-acetyl-derivative**

$C_6H_4-N_2-C_6H_4(N_2OAc)_2$  [138°], orange needles (Liebermann a. Kostanecki, B. 17, 880).

**Benzene-azo-triox-benzene-azo-benzene**

$C_6H_4-N_2-C_6H_4(OH)_3-N_2-C_6H_4$ . **Phloroglucin-bi-diazo-benzene**. Yellowish-brown leaflets. Prepared by the action of diazobenzene nitrate on phloroglucin (Weselsky a. Benedikt, B. 19, 229).

**Benzene-azo-dioxy-benzene-azo-naphthalene**

$C_6H_4-N_2-C_6H_4(OH)_2-N_2-C_{10}H_7$ . [155°]. From diazo-benzene chloride and an alkaline solution of *m*-di-oxy-benzene-azo-naphthalene (Wallach, B. 15, 22).

**Benzene-azo-di-oxy-benzene-azo-toluene**

$C_6H_4-N_2-C_6H_4(OH)_2-N_2-C_6H_4(CH_3)$  [144]. Prepared by the action of diazo-benzene chloride on an alkaline solution of *m*-dioxy-benzene-azo-toluene, or of diazo-toluene chloride on an alkaline solution of benzene-azo-resorcin; in either case the same three isomerides are simultaneously produced and are separated by means of their different solubilities.

(a)-**Compound** [196°]. Golden brown needles. Dissolves with a red colour in  $H_2SO_4$  and NaOH.

E 3

Sol. alcohol and chloroform. In *o*-acetyl-derivative forms yellow needles, [176°].

(*α*)-Compound [241°]. Dissolves with a red colour in  $H_2SO_4$  and in aqueous NaOH. Its di-*o*-acetyl-derivative forms yellow needles, [196°].

(*β*)-Compound [206°]. Brownish-black microscopic crystals. Insol. aqueous NaOH, dissolves in  $H_2SO_4$  to a blue solution. Sl. sol. alcohol, m. sol. chloroform (Wallach, *B.* 15, 2821).

**Benzene-azo-oxythymene-azo-benzene**

$C_6H_5-N_2-C_6H_4MePr(OH)-N_2-C_6H_5$ . Thymol-di-azo-benzene. [168°]. Formed, together with benzene-azo-thymol, by the action of diazobenzene chloride on thymol (Mazzara, *G.* 15, 52, 228). Silky needles, sol. chloroform. By reduction with tin and HCl, and subsequent treatment with  $FeCl_3$ , it is converted into oxy-thymoquinone.

**Benzene-azo-o-oxy-toluene-azo-benzene**

$C_6H_5-N_2-C_6H_4Me(OH)-N_2-C_6H_5$ , [115°]. Obtained by the action of (2 mols. of) diazobenzene chloride on an alkaline solution of *o*-cresol (Nörling, *B.* 17, 364). Reddish-brown plates. V. sl. sol. cold alcohol. Dissolves in alkalis with a yellowish red colour.

*Acetyl derivative* [121°], yellow needles, v. sol. alcohol, ether, and benzene.

**Benzene-azo-m-oxy-toluene-azo-benzene**

$C_6H_5-N_2-C_6H_4Me(OH)-N_2-C_6H_5$ , [149°]. Obtained by the action of (2 mols. of) diazobenzene chloride on an alkaline solution of *m*-cresol. Reddish-brown plates. Sol. ether, benzene, and hot alcohol, sl. sol. cold alcohol.

*Acetyl derivative* [157°], small yellowish-brown needles (Nörling & Kohn, *B.* 17, 367).

**Benzene-azo-di-phenyl-urea-azo-benzene**

$C_6H_5-N_2-C_6H_4NH.CO.NH.C_6H_5-N_2-C_6H_5$ , [270°]. Formed by the action of carbonyl chloride on benzene-azo-aniline (Berju, *B.* 17, 1404; *C. C.* 1884, 871). Small plates. Sol. chloroform and benzene, sl. sol. alcohol.

**Benzene-azo-di-phenyl-thio-urea-azo-benzene**

$C_6H_5-N_2-C_6H_4NH.CS.NH.C_6H_5-N_2-C_6H_5$ , [199°]. Formed as a by-product of the action of phenyl-mustard oil on benzene-azo-aniline (Berju, *B.* 17, 1405). Sl. sol. hot chloroform, xylene, and acetic acid, v. sl. sol. alcohol, benzene, and  $CS_2$ .

**Benzene-azo-pyrrol-azo-benzene**

probably  $\begin{array}{c} NH \\ | \\ C_6H_5-N_2-C_6H_4-NH-CH \end{array}$  [131°]. Obtained by combining (2 mols. of) diazo-benzene chloride with (1 mol. of) pyrrol in alkaline solution. Red crystalline solid. Sublimable. M. sol. ether and benzene, sl. sol. alcohol, nearly insol. water. Possesses basic properties. Dissolves in dilute HCl with a reddish-yellow colour; in conc.  $H_2SO_4$  with a splendid blue colour. Its alcoholic solution is turned magenta-red by NaOH, reddish-violet by conc. HCl (O. Fischer & Hepp, *B.* 19, 2251).

**Benzene-azo-pyrrol-(*β*)-azo-naphthalene**

probably  $\begin{array}{c} NH \\ | \\ C_6H_5-N_2-C_6H_4-NH-CH \end{array}$  [151°]. Formed

by the combination of diazo-benzene chloride with pyrrol-(*β*)-azo-naphthalene or of (*β*)-azo-naphthalene chloride with pyrrol-azo-benzene, in alkaline alcoholic solution. Red plates, with bluish reflection. Sl. sol. alcohol (O. Fischer & Hepp, *B.* 19, 2256).

**Tri-bromo-benzene-azo-di-phenyl-di-isoindole-azo-tri-bromo-benzene**

[150°]. Orange yellow prisms. Soluble in most ordinary solvents except water. Formed by the action of tri-bromo-diazo-benzene chloride on di-phenyl-di-iso-indole. —  $B^*HCl_2$ : slender yellowish-brown needles (Möhlau, *B.* 15, 2490).

**Di-bromo-oxy-benzene-azo-di-phenyl-di-isoindole-azo-di-bromo-phenol**

[198°]. Yellowish-green prisms. Soluble in alcohol, dyes wool orange and silk yellow. Formed by the action of di-bromo-diazo-phenol on di-phenyl-di-isoindole. —  $B^*HCl_2$ : short metallic glistening prisms, insol. water (Möhlau, *B.* 15, 2492).

***ψ*-Cumene-azo-m-di-oxy-benzene-azo-*ψ*-cumene**

Formed, together with cumene-azo-resorcin, by combining diazo-cumene chloride (from amido-pseudo-cumene [62°]) with resorcin (Liebermann & Kostanecki, *B.* 17, 882). Small red needles. Dissolves in  $H_2SO_4$  with a red colour. Insoluble in alkalis.

***p*-Di-methyl-amido-benzene-*p*-azo-benzene-azo-(*β*)-naphthol**

$HO.C_6H_4-N_2-C_6H_4-N_2-C_6H_4.NMe_2$ , [210°]. Got by pouring a diazotised solution of *p*-amido-benzene-azo-dimethylaniline hydrochloride into a solution of (*β*)-naphthol in NaOH (Meldola, *C. J.* 45, 109). Bronzy green needles. Sl. sol. alcohol, v. sol. hot  $C_6H_5O_2$ , benzene, and chloroform. Solutions in the above solvents are red; in alcoholic NaOH, red; in conc.  $H_2SO_4$ , green, turned blue by dilution. An alcoholic solution is turned blue by HCl.

***p*-Di-methyl-amido-benzene-*p*-azo-benzene-azo-(*α*)-naphthol**

$HO.C_6H_4.N_2-C_6H_4-N_2-C_6H_4.NMe_2$ . Prepared like its (*β*) isomeride (M.). Its properties are similar, except that the solution in alcoholic KOH is violet. It decomposes below 300°.

**m-methyl-amido-benzene-azo-**

**resorcin**  
 $(HO)_2C_6H_3-N_2-C_6H_4-N_2-C_6H_4NMe_2$ . Brown powder. Decomposed before melting. Sl. sol. boiling alcohol, the solution being reddish-orange and turned first violet, then blue by adding HCl. Sl. sol. glacial acetic acid, the solution being red when hot, violet when cold. Insoluble in toluene. Solution in alcoholic KOH is reddish-violet. Solution in conc.  $H_2SO_4$  is violet, becoming blue on dilution (Meldola, *C. J.* 45, 110).

**Di-methyl-amido-benzene-p-azo-benzene-azo-phenol**  
 $HO.C_6H_4-N_2-C_6H_4-N_2-C_6H_4NMe_2$ . Brown powder, forming a brown solution in aqueous KOH, and a red solution in alcoholic KOH. Resembles the analogous di-methyl-amido-benzene-p-azo-benzene-azo-resorcin (q. v.) (Meldola, *C. J.* 45, 111).

**Di-methyl-amido-benzene-azo-toluene-azo-(β)-naphthol**  
 $(2) \quad (1) \quad (1)$   
 $C_6H_4(NMe_2)-N_2-C_6H_4Me-N_2-C_{10}H_7OH$ . From diazotised di-methyl-amido-benzene-azo-p-toluidine and (β)-naphthol (Wallach, *A.* 234, 358). Red needles (from chloroform), insol. water.

**Di-methyl-amido-benzene-azo-toluene-azo-phenol**  
 $(3) \quad (1) \quad (1)$   
 $C_6H_4(NMe_2)-N_2-C_6H_4Me-N_2-C_6H_4OH$  [160°]. From diazotised  $C_6H_4(NMe_2)-N_2-C_6H_4MeNH_2$  and phenol (Wallach, *A.* 234, 357). Orange needles.

**(α)-naphthalene-azo-pyrrol-(α)-azo-naphthalene**  
 $C_{10}H_7-N_2-C_6H_4NH-N_2-C_{10}H_7$ ,  
 $C_{10}H_7.N_2.C=CH$   
 probably  $\begin{matrix} NH \\ | \\ C_6H_4.N_2.C=CH \end{matrix}$ .

Formed by adding (α)-diazo-naphthalene chloride (2 mols.) to an alkaline solution of pyrrol (1 mol.). Metallic-glistening needles. Sol. alcohol with a dark yellowish-red colour. Dissolves in conc.  $H_2SO_4$  with a blue colour (O. Fischer a. Hepp, *B.* 19, 2255).

**(β)-Naphthalene-azo-pyrrol-(β)-azo-naphthalene**  
 $C_{10}H_7-N_2-C_6H_4NH-N_2-C_{10}H_7$ ,  
 $C_{10}H_7.N_2.C=CH$   
 probably  $\begin{matrix} NH \\ | \\ C_6H_4.N_2.C=CH \end{matrix}$ .

adding (β)-diazo-naphthalene chloride (2 mols.) to an alkaline solution of pyrrol (1 mol.). Glistening coppery plates. Sl. sol. alcohol. The alcoholic solution is turned reddish-violet by conc. HCl. Dissolves in conc.  $H_2SO_4$  with a blue colour (O. Fischer a. Hepp, *B.* 19, 2255).

**m-Nitro-benzene-p-azo-benzene-(α)-azo-(β)-naphthol**  
 $NO_2.C_6H_4-N_2-C_6H_4-N_2-C_{10}H_7OH$ . [α. 218°]. From diazotised  $NO_2.C_6H_4.N_2.C_6H_4NH_2$  and (β)-naphthol. Small yield (Meldola, *C. J.* 45, 113). Orange crystals with green lustre. Solutions in  $C_2H_5O$  and in toluene are orange; in alcoholic NaOH, violet; in conc.  $H_2SO_4$ , green, turned blue on dilution.

**m-Nitro-benzene-(α)-azo-naphthalene-(α)-azo-(α)-naphthol**  
 $NO_2.C_6H_4-N_2-C_{10}H_7-N_2-C_{10}H_7OH$ . A dark amorphous powder. Solutions in toluene, chloroform and glacial acetic acid are red; in conc.  $H_2SO_4$ , dark indigo violet, becoming blue on dilution; in alcoholic potash, greenish-blue (Meldola, *C. J.* 45, 116).

**m-nitro-benzene-(β)-naphthol**

$NO_2.C_6H_4-N_2-C_{10}H_7-N_2-C_{10}H_7OH$ . From m-nitro-benzene-(α)-azo-(α)-naphthylamine by diazotising and treating with (β)-naphthol (Meldola, *C. J.* 45, 115). Minute bronzy needles (from toluene). Blackens at 245°. Insol. alcohol or glacial acetic acid. Solutions in chloroform and in hot aniline are violet; in toluene red when hot, reddish-violet when cold; in boiling alcoholic KOH, blue; in conc.  $H_2SO_4$ , olive colour, on dilution, blue and then violet.

**m-nitro-benzene-(α)-azo-naphthalene-azo-resorcin**  
 $NO_2.C_6H_4-N_2-C_{10}H_7-N_2-C_6H_4(OH)_2$ . Bronzy powder, not very soluble. Solutions in boiling alcohol are reddish; in glacial acetic acid, toluene and chloroform, orange; in aqueous or alcoholic KOH, blue; in conc.  $H_2SO_4$ , green, changing to bluish-green on dilution (Meldola, *C. J.* 45, 116).

**p-Nitro-benzene-azo-m-xylene-azo-(α)-naphthol**  
 $NO_2.C_6H_4-N_2-C_6H_4Me_2-N_2-C_{10}H_7OH$ . Preparation and properties are similar to those of the preceding (β)-compound.

**Sulphonic acid**  
 $NO_2.C_6H_4-N_2-C_6H_4Me_2-N_2-C_{10}H_7(SO_3H)(OH)$ . Similar to the corresponding (β)-compound, but dyes reddish-brown.

**p-Nitro-benzene-azo-m-xylene-azo-β-naphthol**  
 $NO_2.C_6H_4-N_2-C_6H_4Me_2-N_2-C_{10}H_7OH$  [278°]. From  $NO_2.C_6H_4-N_2-C_6H_4Me_2NH_2$  by diazotising and treating with sodium (β)-naphthol (Meldola, *C. J.* 43, 431). Green scales (from toluene). Scarcely soluble in alcohol or glacial acetic acid. Forms a crimson solution in boiling aniline or nitrobenzene, and a green solution in conc.  $H_2SO_4$ , turned violet by dilution.

**Sulphonic acid**  
 $NO_2.C_6H_4.N_2.C_6H_4Me_2.N_2.C_{10}H_7(OH)SO_3H$ . Gotby using  $C_{10}H_7(OH)SO_3H$ . Dyes claret-red.

**p-Nitro-benzene-azo-m-xylene-azo-phenol**  
 $NO_2.C_6H_4-N_2-C_6H_4Me_2-N_2-C_6H_4OH$ . Orange powder. Sl. sol. alcohol and benzene, v. sol. hot aniline. Solutions are orange. Solution in alcoholic NaOH is reddish-violet. Solution in conc.  $H_2SO_4$  is blue (Meldola, *C. J.* 43, 436).

**p-Nitro-benzene-azo-m-xylene-azo-resorcin**  
 $NO_2.C_6H_4-N_2-C_6H_4Me_2-N_2-C_6H_4(OH)_2$ . [231°]. Brown powder. Forms orange solutions in boiling alcohol, toluene, and glacial acetic acid. Solution in alcoholic NaOH is red, turned violet by excess of NaOH. Conc.  $H_2SO_4$  forms a blue solution (Meldola, *C. J.* 43, 436).

**p-Oxy-benzene-p-azo-benzene-(α)-azo-(α)-naphthol**  
 $C_6H_4(OH)-N_2-C_6H_4-N_2-C_{10}H_7OH$ . From diazotised p-amido-benzene-azo-(α)-naphthol and an alkaline solution of phenol (Meldola, *C. J.* 47, 665). Dark amorphous powder. Its solution in conc.  $H_2SO_4$  is indigo-blue; in boiling toluene, orange; in alcohol, red; in KOH aq., dull red; and in alcoholic NaOH, deep claret colour.

**p-Oxy-benzene-p-azo-benzene-(α)-azo-(β)-naphthol**  
 $HO.C_6H_4-N_2-C_6H_4-N_2-C_{10}H_7OH$ . [225°]. From p-amido-benzene-azo-(β)-naphthol by diazotising and mixing with an alkaline solution of phenol (Meldola, *C. J.* 47, 666). Red warty concretions. Its solution in conc.  $H_2SO_4$  is bluish-green, and becomes violet on dilution.

its solution in boiling toluene, or boiling alcohol, is red. Its solution in KOHAq is reddish-violet.

**m-Di-oxo-benzene-p-azo-benzene-(a)-azo-(a)-naphthol**

[4:2:1]  $C_6H_4(OH)_2-N_2-C_6H_4-N_2-C_{10}H_7(OH)$ . Formed by mixing diazotised p-amido-benzene-azo-(a)-naphthol with a solution of resorcin in dilute NaOH (Meldola, C. J. 47, 665). Bronzy-green powder; sl. sol. toluene and acetic acid, forming a red solution. Its solution in KOHAq is blue; its solution in  $NH_4Aq$  is violet. It is decomposed by heat without fusion.

**m-Di-oxo-benzene-p-azo-benzene-(a)-azo-(β)-naphthol**

[4:2:1]  $C_6H_4(OH)_2-N_2-C_6H_4-N_2-C_{10}H_7(OH)$ . From diazotised p-amido-benzene-azo-(β)-naphthol and an alkaline solution of resorcin (Meldola, C. J. 47, 666). Bronzy-green powder. Its solution in conc.  $H_2SO_4$  is deep bluish-green; in dilute aqueous alkalis, violet. Sl. sol. toluene forming a red solution.

**m-Oxy-benzene-azo-benzene-p-azo-phenol**

[8:1]  $HO.C_6H_3(OH)-N_2-C_6H_4-N_2-C_6H_4.OH$  [1:4]. Dark powder. Easily soluble in alkalis. Formed by diazotising amido-benzene-m-azo-phenol ( $C_6H_4(OH)-N_2-C_6H_4.NH_2$ ) and combining it with phenol (Wallach a. Schulze, B. 15, 3021).

**p-Oxy-benzene-azo-benzene-p-azo-phenol**

[4:1]  $HO.C_6H_4-N_2-C_6H_4-N_2-C_6H_4.OH$  [1:4]. [o. 207]. From diazotised amido-benzene-p-azo-phenol and a solution of phenol in dilute alkali (Meldola, C. J. 47, 660). Amorphous brown powder. Its solution in conc.  $H_2SO_4$  is violet, unchanged on considerable dilution; v. sol.  $NH_4Aq$  and KOHAq forming a red solution; insol. boiling toluene; forms an orange solution in hot phenol or aniline.

**m-Di-oxo-benzene-p-azo-benzene-azo-resorcin**

[4:3:1]  $C_6H_4(OH)_2-N_2-C_6H_4-N_2-C_6H_4(OH)_2$  [1:2:4]. From diazotised p-amido-benzene-azo-resorcin and an alkaline solution of resorcin (Meldola, C. J. 47, 661). Dull bronze-like powder, v. sl. sol. alcohol, insol. toluene. Its solutions in conc.  $H_2SO_4$  and in alkalis are violet.

**Oxy-carboxy-benzene-azo-benzene-(a)-azo-(β)-naphthol**

[4] (3) (1) (1)(a) (β)  $C_6H_4(CO_2H)(OH)-N_2-C_6H_4-N_2-C_{10}H_7(OH)$  [above 255]. From diazotised p-amido-benzene-azo-salicylic acid and an alkaline solution of (β)-naphthol (Meldola, C. J. 47, 668). Minute brown needles (from boiling aniline). V. sl. sol. boiling toluene, sl. sol. alcohol and glacial  $H_2OAc$ . Its solution in conc.  $H_2SO_4$  is greenish-blue, changing to violet on dilution. Its solution in KOHAq is reddish-violet.

**Oxy-cymene-azo-tri-phenyl-methane-azo-thymol**

[6:3:4:1]  $C_{10}H_7MePr(OH)-N_2-C_6H_4-N_2-C_6H_4MePr(OH)$  [170]. Formed by mixing diazotised diaminodiphenylmethane hydrochloride with an alkaline solution of thymol (Mazzara, G. 15, 44). Amorphous black powder. After reduction and oxidation it gives thymequinone.

**(a)-Oxy-naphthalene-p-azo-benzene-(a)-naphthol**

(a) (a)(4) (1)(a) (a)  $C_{10}H_7(OH)-N=N-C_6H_4-N=N-C_{10}H_7(OH)$ . Formed by diazotising p-amido-benzene-azo-(a)-naphthol and mixing the product with an

alkaline solution of (a)-naphthol (Meldola, C. J. 47, 664). Green lustrous powder; v. sl. sol. glacial  $H_2OAc$ , alcohol, and toluene, m. sol. boiling aniline, forming a red solution. Its solution in NaOHAq is blue, in conc.  $H_2SO_4$  blue, turned violet on dilution. With  $Ac_2O$  and NaOAc it forms on heating a di-acetyl derivative.

**(β)-Oxy-(a)-naphthalene-p-azo-benzene-(a)-azo-(β)-naphthol**

(a) (a)(1) (4)(a) (β)  $C_{10}H_7(OH)-N=N-C_6H_4-N=N-C_{10}H_7(OH)$  [over 275°]. From diazotised p-amido-benzene-azo-(β)-naphthol and an alkaline solution of (β)-naphthol (Meldola, C. J. 47, 664). Dull bronzy powder, or green needles (from hot aniline). Insol. boiling alcohol, or NaOHAq; sol. cold alcoholic NaOH, forming a violet solution. Sl. sol. hot toluene forming a magenta solution. Conc.  $H_2SO_4$  forms a blue solution, turned violet on dilution.

**(a)-Oxy-naphthalene-p-azo-benzene-azo-(β)-naphthol**

(a) (a)(1) (4)(a) (β)  $C_{10}H_7(OH)-N=N-C_6H_4-N=N-C_{10}H_7(OH)$  [236°]. From diazotised p-amido-benzene-azo-(a)-naphthol and an alkaline solution of (β)-naphthol (Meldola, C. J. 47, 665). Dull bronzy powder, v. sl. sol. boiling alcohol; m. sol. boiling toluene and glacial acetic acid forming violet solutions; conc.  $H_2SO_4$  forms a blue solution, becoming violet on dilution.

**(a)-Oxy-naphthalene-p-azo-benzene-azo-(β)-naphthol-di-sulphonic acid**

(a) (a)(1) (4) (β)  $C_{10}H_7(OH)-N=N-C_6H_4-N=N-C_{10}H_7(SO_3H)_2(OH)$ . From diazotised p-amido-benzene-azo-(a)-naphthol and an alkaline solution of (β)-naphthol-di-sulphonic acid. Its sodium salt is violet and gelatinous; it is an indigo-blue dye (Meldola, C. J. 47, 665).

(β)-Oxy-naphthalene-azo-benzene-azo-(β)-naphthol-di-sulphonic acid. Is similar to the last body, but of greater stability (M.).

**Oxy-di-sulpho-naphthalene-azo-benzene-azo-(β)-naphthol-di-sulphonic acid**

$C_{10}H_7(SO_3H)_2(OH)-N_2-C_6H_4-N_2-C_{10}H_7(SO_3H)_2(OH)$ . Glistening greenish needles. Dyes wool and silk a deep indigo-blue, which, however, is very unstable to light. Is prepared by diazotising the mono-acetyl derivative of p-phenylene-diamine and combining it with (β)-naphthol-di-sulphonic acid (modification insoluble in spirit), the product  $C_6H_4(NHAc).N_2.C_{10}H_7(OH)(SO_3H)_2$ , which is a scarlet colouring matter, is saponified, diazotised, and again combined with (β)-naphthol-di-sulphonic acid (Nietzki, B. 17, 344; 1850).

**Phenyl-amido-benzene-p-azo-benzene-azo-(β)-naphthol**

$HO.C_6H_4-N_2-C_6H_4-N_2-C_{10}H_7.NH.C_6H_5$  [204°]. From p-amido-benzene-azo-di-phenylamine by diazotising and adding sodium (β)-naphthol (Meldola, C. J. 43, 442). Warty scales with bronze lustre. Sl. sol. boiling alcohol, v. sol. benzene. The solutions are red. In glacial acetic acid the solution is red when hot, violet when cold. Solution in conc.  $H_2SO_4$  is greenish-blue, solution in alcoholic KOH is red but turned blue by HCl (characteristic).

**Phenyl-ethyl-amido-benzene-azo-benzene-azo-(β)-naphthol**

$HO.C_6H_4-N_2-C_6H_4-N_2-C_{10}H_7.NE_2.C_2H_5$

From *p*-diao-nitro-benzene by combining with ethyl-di-phenyl-amine, reducing with ammonium sulphide, diazotising the product and treating with (β)-naphthol. Bronzy powder. Solutions in alcoholic KOH, alcohol, and benzene are red; in conc. H<sub>2</sub>SO<sub>4</sub> indigo-blue, turned bright blue on diluting. HCl turns the alcoholic solution blue (Meldola, *C. J.* 45, 111).

*p*-Sulpho-benzene-azo-benzene-azo-(β)-naphthol-(β)-sulphonic acid

$$\text{C}_6\text{H}_4(\text{SO}_3\text{H})-\text{N}=\text{N}-\text{C}_6\text{H}_4-\text{N}=\text{N}-\text{C}_{10}\text{H}_6(\text{SO}_3\text{H})(\text{OH})$$
  
From diazotised *p*-amido-benzene-azo-benzene sulphonic acid and an ammoniacal solution of sodium (β)-naphthol 'a'-sulphonic acid (Bayer & Co., *B.* 15, 1351). The sodium salt is a scarlet dye (orocoeine scarlet). Conc. H<sub>2</sub>SO<sub>4</sub> forms a blue solution. The absorption spectrum has been studied by Hartley (*C. J.* 51, 195).

*p*-Sulpho-benzene-azo-benzene-azo-tolylene diamine

$$\text{C}_6\text{H}_4(\text{SO}_3\text{H})-\text{N}=\text{N}-\text{C}_6\text{H}_4-\text{N}_2-\text{C}_6\text{H}_4(\text{NH}_2)_2$$
  
Reddish-brown microscopic needles. Formed by combining diazo-benzene-azo-benzene-*p*-sulphonic acid with tolylene-diamine (Griess, *B.* 16, 2036).

Sulpho-benzene-azo-di-phenyl-di-isindole-azo-benzene sulphonic acid

Formed by the action of diazo-benzene-sulphonic acid on di-phenyl-di-isindole. Metallic glistening brown scales. Very slightly soluble in all solvents. Dyes silk and wool nearly the same shade as chrysoidine. On reduction it gives sulphanilic acid and di-amido-di-phenyl-di-isindole.

Salts.—A"Na<sub>2</sub>aq: yellow plates.—A"Ag<sub>2</sub>: red prisms (Möhlau, *B.* 15, 2495).

Sulpho-benzene-azo-sulpho-benzene-(α)-azo-(β)-naphthol

$$\text{C}_6\text{H}_4(\text{SO}_3\text{H})-\text{N}_2-\text{C}_6\text{H}_4(\text{SO}_3\text{H})-\text{N}_2-\text{C}_{10}\text{H}_6\text{OH}$$
  
From diazo-sulpho-benzene-azo-benzene sulphonic acid and an alkaline solution of (β)-naphthol (Nietzki, *B.* 13, 800). The sodium salt is a red dye (*Biebrich scarlet*). Conc. H<sub>2</sub>SO<sub>4</sub> forms a green solution. Its absorption spectrum has been studied by Hartley (*C. J.* 51, 194).

Sulpho-benzene-azo-sulpho-benzene-(β)-azo-naphthyl-*p*-tolyl-amine ('Wool-black')

$$\text{C}_6\text{H}_4(\text{SO}_3\text{H})-\text{N}_2-\text{C}_6\text{H}_4(\text{SO}_3\text{H})-\text{N}_2-\text{C}_6\text{H}_4\text{NHC}_6\text{H}_4$$
  
The coml. product is a bronzy powder. V. sol. hot water with a violet-blue colour. Dissolves in conc. H<sub>2</sub>SO<sub>4</sub> with a deep indigo-blue colour. Formed by combination of diazotised amido-sulpho-benzene-azo-benzene-sulphonic acid with *p*-tolyl-(β)-naphthylamine. By boiling with moderately dilute H<sub>2</sub>SO<sub>4</sub> it is decomposed into tolu-(α)-naphthazine [169°] and amidoazo-benzene-di-sulphonic acid:

The Ca and Ba salts are insoluble black pps. (Witt, *B.* 20, 579).

*p*-Toluene-azo-*m*-diamido-benzene-azo-(β)-naphthalene  $\text{C}_6\text{H}_4-\text{N}_2-\text{C}_6\text{H}_4(\text{NH}_2)_2-\text{N}_2-\text{C}_{10}\text{H}_7$ . Formed by the combination of *p*-diao-toluene with (β)-naphthalene-azo-*m*-phenylene-diamine (Griess, *B.* 16, 2031). Small red glistening plates. V. sol. chloroform.

*p*-Toluene-azo-ethyl-pyrrol-*p*-azo-toluene

Formed by ethylation of toluene-azo-pyrrol-azo-toluene; or by combining diazo-*p*-toluene chloride (2 mol.) with ethyl-pyrrol (1 mol.) in alkaline solution. Steel-blue needles. Sl. sol. alcohol (O. Fischer & Hepp, *B.* 19, 2254).

Toluene-azo-dioxy-benzene-azo-toluene

$$\text{C}_6\text{H}_4-\text{N}_2-\text{C}_6\text{H}_3(\text{OH})_2-\text{N}_2-\text{C}_6\text{H}_4$$
. By the action of *p*-diao-toluene chloride on an alkaline solution of *p*-toluene-azo-resorcin two isomerides are formed which are separated by their different solubilities in alkalis.

(a)-Compound [256°]. Yellow felted needles.

Sparingly soluble in alcohol and cold chloroform.

(β)-Compound [203°]. Brownish-black microscopic needles (Wallach, *B.* 15, 2825).

Toluene-azo-trioxybenzene-azo-toluene

$$\text{C}_6\text{H}_4\text{Me}-\text{N}_2-\text{C}_6\text{H}_2(\text{OH})_3-\text{N}_2-\text{C}_6\text{H}_4\text{Me}$$
  
Long red needles. Prepared by the action of diazo-toluene nitrate on phloroglucin (Wesolaky & Benedikt, *B.* 12, 227).

Toluene-azo-pyrrol-azo-toluene

Formed by adding (2 mols.) diazo-*p*-toluene chloride to an alkaline solution of pyrrol (1 mol.). Red prisms with steel-blue reflex. Sl. sol. alcohol. Its alcoholic solution is turned reddish-violet by conc. HCl. Dissolves in conc. H<sub>2</sub>SO<sub>4</sub> with a blue colour (O. Fischer & Hepp, *B.* 19, 2254).

Toluene-*o*-azo-toluene-azo-(α)-naphthol

Formed by combination of *o*-diao-azo-toluene with (α)-naphthol. Brownish-red needles (from aniline). Sl. sol. ordinary solvents. Insol. aqueous NaOH, sol. alcoholic NaOH with a violet-red colour. By SnCl<sub>2</sub> it is slowly reduced to amido-(α)-naphthol and tolyl-azimido-toluene  $\text{C}_6\text{H}_4-\text{N}_2-\text{C}_6\text{H}_4$ , together with small quantities of *p*-toluidine and tolylene-*o*-diamine (Zincke & Lawson, *B.* 20, 1178).

Toluene-*o*-azo-toluene-azo-(β)-naphthol

by combination of *o*-diao-azo-toluene with (β)-naphthol. Long dark-red four-sided prisms, with green reflex. V. sol. benzene, and chloroform, sl. sol. alcohol, acetone, and petroleum-spirit. Dissolves in alcoholic NaOH only slightly.

By  $\text{SnCl}_4$  it is reduced to (a)-amido-( $\beta$ )-naphthol and tolyl-azimido-toluene  $\text{C}_6\text{H}_4\text{N}_2\text{C}_6\text{H}_4$ , together with small quantities of *p*-toluidine and tolylene-diamine (Zincke a. Lawson, *B.* 20, 1179).

**Toluene-*p*-azo-toluene- $\alpha$ - $\beta$ -naphthol**

$\text{C}_6\text{H}_4(\text{CH}_3)_2\text{N}_2\text{C}_6\text{H}_3(\text{CH}_3)_2\text{N}_2\text{C}_{10}\text{H}_7(\text{OH})$ . [186°]. Formed by combination of *p*-diao-azo-toluene with ( $\beta$ )-naphthol. Deep-red needles. V. sol. hot alcohol and benzene. By  $\text{SnCl}_4$  it is easily reduced, giving (a)-amido-( $\beta$ )-naphthol, *o*-toluidine, and tolylene-*p*-diamine  $\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)_2$  [1:2:5] (Zincke a. Lawson, *B.* 20, 1182).

**Toluene-*o*-azo-toluene-azo-( $\beta$ )-naphthyl-**

$\text{amine C}_6\text{H}_4(\text{CH}_3)_2\text{N}_2\text{C}_6\text{H}_4(\text{CH}_3)_2\text{N}_2\text{C}_{10}\text{H}_7(\text{NH}_2)$ , or the corresponding hydrazimido-formula. [203°]. Formed by combination of *o*-diao-toluene-azo-toluene with ( $\beta$ )-naphthylamine. Deep-red glistening plates. V. sol. benzene and chloroform. By  $\text{SnCl}_4$  it is reduced to tolyl-azimido-toluene  $\text{C}_6\text{H}_4\text{N}_2\text{C}_6\text{H}_4$  and (probably) naphthyl-ene-*o*-diamine (Zincke a. Lawson, *B.* 20, 1180).

**AZO-COMPOUNDS, TERTIARY.**

**Oxy-benzene-*p*-azo-benzene-(a)-azo-naphthalene-azo-phenol**

$\text{HO.C}_6\text{H}_4\text{N}_2\text{C}_6\text{H}_4\text{N}_2\text{C}_{10}\text{H}_6\text{N}_2\text{C}_6\text{H}_4\text{OH}$ . From  $\text{NH}_2\text{C}_6\text{H}_4\text{N}_2\text{C}_{10}\text{H}_6\text{NH}_2$  by diazotising and adding sodic phenate (Meldola, *C. J.* 43, 439). Dull bronzy-green powder. Forms orange solutions with boiling aniline or toluene. Solution in alcoholic KOH is violet; in conc.  $\text{H}_2\text{SO}_4$ , indigo-blue.

**Di-oxy-benzene-*p*-azo-benzene-(a)-azo-naphthalene-azo-resorcin**

$(\text{HO})_2\text{C}_6\text{H}_3\text{N}_2\text{C}_6\text{H}_4\text{N}_2\text{C}_{10}\text{H}_6\text{N}_2\text{C}_6\text{H}_3(\text{OH})_2$ . Brown powder. Its solutions are dull red in alcohol, violet in alcoholic KOH, bluish-green in conc.  $\text{H}_2\text{SO}_4$ .

**( $\beta$ )-oxy-naphthalene-*p*-azo-benzene-(a)-azo-naphthalene-azo-( $\beta$ )-naphthol**

$\text{HO.C}_{10}\text{H}_7\text{N}_2\text{C}_6\text{H}_4\text{N}_2\text{C}_{10}\text{H}_6\text{N}_2\text{C}_{10}\text{H}_7\text{OH}$ . Formed by diazotising amido-benzene-azo-( $\beta$ )-naphthylamine  $\text{NH}_2\text{C}_6\text{H}_4\text{N}_2\text{C}_{10}\text{H}_6\text{NH}_2$  and treating with an alkaline solution of ( $\beta$ )-naphthol (Meldola, *C. J.* 43, 437). The pp. may be separated by crystallisation from hot aniline into two modifications, one remaining in solution, the other separating as needles with green lustre.

**Crystalline form** [c. 295°]. Insoluble in boiling alcohol, acetone, or glacial acetic acid, hardly soluble in chloroform or benzene. Forms violet solutions with aniline or nitrobenzene. Solution in conc.  $\text{H}_2\text{SO}_4$  is deep inky blue. Alcoholic KOH forms, with difficulty, a blue solution.

**Soluble form**.—Soluble in the above liquids. Its solution in boiling glacial acetic acid is violet when hot, blue when cold. Solution in conc.  $\text{H}_2\text{SO}_4$  is clear indigo-blue. Alcoholic potash forms a violet solution.

**Di-sulphonic acid**.—From ( $\beta$ )-naphthol-sulphonic acid and diazotised

$\text{NH}_2\text{C}_6\text{H}_4\text{N}_2\text{C}_{10}\text{H}_6\text{NH}_2$ .  
(a)-Oxy-naphthalene-*p*-azo-benzene-(a)-azo-naphthalene-azo-(a)-naphthol. Similar to the preceding. Bronzy powder, forming a blue solution in alcoholic KOH, and an indigo-blue solution with conc.  $\text{H}_2\text{SO}_4$ .

**( $\beta$ )-Oxy-naphthalene-*p*-azo-xylylene-azo-( $\beta$ )-naphthol**

$\text{HO.C}_6\text{H}_4\text{N}_2\text{C}_6\text{H}_4\text{N}_2\text{C}_6\text{H}_3(\text{Me})_2\text{N}_2\text{C}_{10}\text{H}_7\text{OH}$ . From  $\text{NH}_2\text{C}_6\text{H}_4\text{N}_2\text{C}_6\text{H}_3(\text{Me})_2\text{NH}_2$  by diazotising and adding sodium ( $\beta$ )-naphthol (Meldola, *C. J.* 43, 439). Small green needles (from xylene). Its solution in aniline is reddish-violet; in xylene, violet; in hot alcoholic KOH, bluish-violet; in conc.  $\text{H}_2\text{SO}_4$ , greenish-blue, becoming blue on dilution. It is insoluble in alcohol and in glacial acetic acid. Its sulphonic acid dyes silk and wool dull violet.

**Tri-oxy-tri-naphthalene-hexa-azo-tri-phenyl-carbinol**  $\text{HO.C(C}_6\text{H}_4\text{N}_2\text{C}_{10}\text{H}_6\text{OH})_3$ . From diazotised para-rosaniline and (a)- or ( $\beta$ )-naphthol in alkaline solution (Meldola, *C. J.* 47, 668). Orange amorphous powders. Similar compounds may be got from ordinary rosaniline. They dye silk and wool orange.

**AZO-COTTON DYES**. The azo-dye-stuffs obtained from benzidine and its homologues (Congo-red, benzopurpurine, fastapurpurine, benzaurine, chrysamine, benzazurine, &c.) have the special characteristic of dyeing cotton without a mordant. This property depends upon the constitution of the diphenyl molecule, for benzidine itself (and other diphenyl bases) readily combines with the cotton fibre. This is easily shown by allowing cotton to soak for 24 hours in a cold solution of benzidine hydrochloride, wringing, drying at the ordinary temperature, and washing thoroughly with hot and cold water; if the cotton thus mordanted with benzidine is now passed through a dilute solution of nitrous acid, and finally treated with a solution of (a)-naphthylamine-sulphonic acid it becomes dyed with Congo-red (Möhlau, *B.* 19, 2014).

Tetrazo-diphenyl (diazotised benzidine) forms red dye-stuffs by combination with (a)- and ( $\beta$ )-mono-sulphonic acids of ( $\beta$ )-naphthol or with the G di-sulphonic acid. The R di-sulphonic acid (Na salt insoluble in spirit) however exhibits a very peculiar reaction. One mol. of tetrazo-diphenyl combines with one mol. of the R di-sulphonate forming a dye-stuff which is red. If two mols. of the sulphonate are taken one mol. remains in solution unused. If now the ppd. red colouring matter is heated with the mother liquor, the second mol. of di-sulphonate is taken up and a blue colouring matter is produced. A similar reaction has been observed with many other di-amido-bodies (Sohultz, *B.* 17, 461).

In general, the tetrazo-derivatives of diphenyl, ditolyl, &c. (obtained by diazotising benzidine and its homologues) can combine with either one or two mols. of a phenol, amine, or their sulphonic and carboxylic acids. The compounds with one mol., viz.,  $\text{R}^1\text{N}_2\text{C}_6\text{H}_4\text{N}_2\text{C}_6\text{H}_4\text{N}_2\text{R}^2$ , are tolerably stable, and sparingly soluble; by boiling with water or with alcohol the uncombined diazo-group is replaced by OH or by hydrogen. These half-conjugated diazo-compounds readily combine with a second mol. of phenol or amine, so that mixed azo-compounds can be thus obtained. The latter bodies are colouring-matters of various shades, and dye cotton direct without a mordant (Lange, *B.* 19, 1697; Martius, *B.* 19, 1756).

The most important (Hæmaphys yellow, Hæmaphys purple, carotene, etc.) obtained by combining two mols. of a phenol, amine or respective sulphonic acid, or one mol. of one amine or phenol and one mol. of another, with the tetrazo-compound derived from di-*p*-amido-di-phenyl-ethylene or its sulphonic acids, have the property of dyeing unmordanted cotton from a soap-bath. The compound from (a)-naphthol-sulphonic acid dyes cotton a bluish-violet, (β)-naphthol-R-di-sulphonic acid a blue, (α)-naphthylamine-sulphonic acid a red salicylic acid a yellow, &c. (Bender a. Schultz, *B. 19*, 3234). The di-amido-derivatives of fluorene also give colouring matters which dye cotton. To the class of cotton colours also belongs the compound which has recently been introduced under the name of 'Primuline.' This body dyes unmordanted cotton from an alkaline bath a greenish yellow. It is an amido-compound and may be diazotised upon the fibre. By treatment of the cotton thus prepared with solutions of amines or phenols, fast colours (red, orange, and brown) may be produced (Green, *priv. com.*).

**TRIAZOL.** A name given to the hypothetical  $C_3H_3N_3$  or  $HC \begin{array}{c} \text{HN} \text{---} \text{N} \\ \text{||} \\ \text{CH} \end{array}$  (Bladin, *B. 19*, 2598) (*v.* PHENYL-METHYL-TRIAZOL and CYANO-PHENYL METHYL-TRIAZOL).

**AZO-MECONIC-ACETIC ACID** *v.* Di-*ortho*-carboxy-methyl-phthalide-azo-di-*ortho*-phthalide-acetic acid.

**AZO-DI-METHYL-HYDROQUINONE** *v.* Di-*ortho*-benzene-azo-hydroquinone.

**AZO-NAPHTHALENE** *v.* Naphthalene-azo-naphthalene.

**TETRAZONES.** Compounds of the form  $R_2N.N.N.N.R_2$  obtained by oxidising unsymmetrical di-alkylated hydrazines (*q. v.*).

**AZONIUM BASES.** Compounds of the form  $NH_2.NRR'N'(OH)$  (Fischer). The name has been also applied by Witt (*B. 20*, 1183) to compounds

of the form  $X \begin{array}{c} \text{NR} \text{---} \text{N} \\ \text{||} \\ \text{Y} \end{array}$ .

**AZO-OPICNIC ACID** is amido-hemipic anhydride, *v.* Hemipic acid.

**AZOPHENINE**  $C_{12}H_9N_3$ . [237°]. Is formed by the action of a variety of azo- and nitroso-compounds (*e.g.* benzene-azo-aniline, toluene-azo-toluidine, phenyl-amido-benzene-azo-benzene, chrysoidine, diphenyl-nitrosamine, nitroso-*l*-methyl-aniline, &c.) upon aniline (Kimich, *B. 1*, 1026). The best method of preparation consists in warming an acetic acid solution of aniline with a nitroso-compound (*e.g.* nitroso-*di*-methyl-aniline) filtering off the crystals of azophenine, washing them with alcohol and recrystallising from aniline or nitro-benzene. If the aniline is replaced by its homologues, the homologues of azophenine are obtained. It forms unstable salts of violet colour. It cannot be acetylated. Conc.  $H_2SO_4$  at 100° yields a sulphonic acid crystallising in violet needles, which form brown crystalline salts. By heating with aniline hydrochloride it is converted into induline (*q. v.*). By heating alone at 860° it is converted into aniline, a violet inter-

mediate body, and fuoridine. The latter is a splendid blue crystalline colouring-matter, the solutions of which have a beautiful red fluorescence and a characteristic absorption spectrum. By reduction with  $SnCl_4$  azophenine yields aniline and a sparingly soluble hydrochloride of an unstable base. The latter, when set free by alkalis, rapidly absorbs oxygen from the air, and changes into a new colouring-matter, the salts of which are indigo-blue (Witt, *B. 20*, 1533; Witt a. Thomas, *C. J.* 43, 112).

**AZO-PHENYL ACETIC ACID** *v.* *Ero*-carboxy-toluene-azo-phenyl-acetic acid.

**AZO-DIPHENYL BLUE** *v.* INDULINE.

**AZO-PHENYLENE**, now called **PRIMULINUM** (*q. v.*).

**AZO-PHTHALIC ACID** *v.* Di-carboxy-benzene-azo-phthalic acid.

**AZO-PYROMELLITIC ACID**  $C_{12}H_4(CO_2H)_6$ . Tetra-ethyl ether  $A^*Et_4$  [194°]; glistering red trimetric tables; easily soluble in alcohol, ether, and acetic acid, insoluble in water; sublimable. Formed by reduction of di-nitro-mellitic ether with zinc-dust and acetic acid. It forms an unstable colourless hydrochloride (Nef, *B. 18*, 2805).

**AZO-RESORCIN** *v.* RESORCIN.

**AZO-RESORUFIN** *v.* RESORCIN.

**AZO-TOLUENE** *v.* Toluene-azo-toluene.

**AZO-TOLUIDINE** *v.* Amido-toluene-azo-toluidine.

**AZOXIMS.** Amidoxims,  $R.C(NOH).NH_2$ , are produced by the union of hydroxylamine with nitriles; these react with acid chlorides,  $R'.CO.Cl$ , or anhydrides,  $(R'CO)_2O$ , with formation of alkoyl derivatives,  $R.C(NO.CO.R').NH_2$ , which under suitable conditions (application of heat, or boiling with water) split off water and change into **sozoxims**  $R.C \begin{array}{c} \text{N.O} \\ \text{N} \end{array} > C.R'$ . The azoxims are very volatile in the vapour of other liquids or in air; many of those boiling above 200° are volatile even in vapour of ether. They sublime at the ordinary temperature of the air (Tiemann, *B. 18*, 1060; 19, 1475).

Chloroformic ether acting upon benzamidoxim produces an azoxim which has the character of a lactam,  $C_6H_5.C \begin{array}{c} \text{N.O} \\ \text{NH} \end{array} > CO$ .

Phenyl-acetamidoxim,

$Ph.CH_2.C(NOH).NH_2$ , does not produce azoxims so readily as benzamidoxim,  $Ph.C(NOH).NH_2$ , but phenyl-acyl-amidoxim (cinnamidoxim),  $Ph.CH:CH.C(NOH).NH_2$ , produces them with great ease.

*m*-Amido-benzoyl-azoxim-benzoyl

$C_6H_5(NH_2).C \begin{array}{c} \text{N.O} \\ \text{N} \end{array} > C.C_6H_5$ . [143°]. Formed by reduction of *m*-nitro-benzoyl-azoxim-benzoyl with alcoholic ammonium sulphide. Crystallises from alcohol or sublimes in long needles. *V. sol.* alcohol, ether, benzene, and chloroform, insol. ligroin and water. By nitrous acid it is diazotised.

Salts.  $-BHCl$ : very sparingly soluble.  $B^*H.Cl.PtCl_4$ : sparingly soluble pp.

*Benzoyl derivative*  $C_6H_5ON.(NH_2)_2$  [218°]; needles; *sol.* boiling alcohol, ether, and benzene, insol. water and ligroin (Schöpf, *B. 18*, 2478).

**Benzoyl-azoxim-benzoyl**  $C_6H_5N_2O$  i.e.  $C_6H_5.C \begin{smallmatrix} N.O \\ \diagup \diagdown \end{smallmatrix} C.C_6H_5$ . [108°]. (290°). Volatile with steam. Sublimes in long white needles. V.D. (H=1) 113.3. V. sol. alcohol, ether, and benzene; v. sl. sol. water.

**Formation.**—1. By heating the benzoyl derivative of benz-amidoxim— $C_6H_5.C(NH_2).N.OBz$ . 2. By heating benz-amidoxim with benzoic acid, or with benzotrichloride.

**Reactions.**—It is an extremely stable substance, being unattacked even by strong  $HNO_3$  or  $H_2SO_4$ . Long boiling with tin and  $HCl$  reduces it to benzonitrile (Tiemann & Krüger, B. 17, 1694).

**Benzoyl-azoxim-benzoyl-o-carboxylic acid**  $C_6H_5.C \begin{smallmatrix} N.O \\ \diagup \diagdown \end{smallmatrix} C.C_6H_5.CO_2H$ . [151°]. Formed by melting together benz-amidoxim and phthalic anhydride. White glistening needles. V. sol. alcohol, ether, and benzene, v. sl. sol. water and ligroin.

**Salts.**—A'Ag: white crystalline pp.—A'Ba<sup>2+</sup>: plates or microscopic needles.—A'Cu: bluish-green pp.—A'PbOH: white granular pp.

**Ethyl ether.**—A'Et: heavy yellow oil. **Amide.**— $C_{11}H_{10}N_2CONH_2$ : [160°], microscopic needles (Schulz, B. 18, 2463).

**Benzoyl-azoxim-benzoyl-m-carboxylic acid**  $C_6H_5.C \begin{smallmatrix} N.O \\ \diagup \diagdown \end{smallmatrix} C.C_6H_5.CO_2H$ . [218°]. Formed by heating benzamidoxim *m*-carboxylic acid with  $BzCl$  (G. Müller, B. 19, 1497). White crystalline powder; sol. alcohol, insol. water.

**Benzoyl-azoxim-butyryl**

$C_6H_5.C \begin{smallmatrix} N.O \\ \diagup \diagdown \end{smallmatrix} C.C_6H_5$ . (265°). Oily fluid. Volatile with steam. Formed by the action of butyric anhydride upon benz-amidoxim, or by eliminating  $H_2O$  from the butyryl derivative of the latter (Schulz, B. 18, 1085).

**Benzoyl-imidoxim-carbonyl**

$C_6H_5.N_2O_2$  i.e.  $C_6H_5.C \begin{smallmatrix} N.O \\ \diagup \diagdown \end{smallmatrix} NH > CO$  and

$C_6H_5.C \begin{smallmatrix} N.O \\ \diagup \diagdown \end{smallmatrix} C(OH)$ . **Benzoyl-azoxim-carbinol**. [198°]. Carbonises at about 300°. Soluble in alcohol, ether, chloroform, benzene, and hot water, sparingly in cold water. The aqueous solution reacts strongly acid to litmus. It decomposes carbonates. Not attacked by  $PCl_5$  or by  $HCl$ . Formed by elimination of alcohol from benzoyl-amidoxim-carbinol ether or, directly, by heating benzoyl-amidoxim with chloroform ether.

**Salts.**—A'Ag: white pp.—A'Cu: green pp. **Ethyl derivative**  $C_6H_5EtN_2O_2$  [36°]: soluble in alcohol, ether, &c., nearly insoluble in water; indifferent body (Falck, B. 18, 2468; 19, 1481).

**Benzoyl-azoxim-ethenyl**  $C_6H_5N_2O$  i.e.

$C_6H_5.C \begin{smallmatrix} N.O \\ \diagup \diagdown \end{smallmatrix} C.CH_2$ . [41°]. (244°). Formed by boiling benzoyl-amidoxim with acetic anhydride (Tiemann & Krüger, B. 17, 1696; 18, 1059; Schulz, B. 18, 1084). Flat prisms. Easily volatile with steam. Sublimes at the ordinary temperature in white needles. V. sol. alcohol, ether, and benzene, sl. sol. water.

**Benzoyl-azoxim-propenyl**

$C_6H_5.C \begin{smallmatrix} N.O \\ \diagup \diagdown \end{smallmatrix} C.C_6H_5$ . (255°). Colourless oil. Volatile with steam. Formed by the action of propionic anhydride upon benz-amidoxim (Schulz, B. 18, 1085).

**Benzoyl-azoxim-propenyl-o-carboxylic acid**

$C_6H_5.C \begin{smallmatrix} N.O \\ \diagup \diagdown \end{smallmatrix} C.CH_2.CH_2.CO_2H$ . [120°]. Formed by fusing benz-amidoxim with succinic anhydride. White trimetric plates or prisms. V. sol. alcohol, ether, hot water and benzene, insol. ligroin. It is not decomposed by warming with  $H_2SO_4$ .

**Salts.**—A'Ag: white crystalline pp.—A'Ca<sup>2+</sup>: long glistening soluble needles.—A'Ba<sup>2+</sup>: short prisms, or monoclinic crystals.—A'Cu: bluish-green granular powder.—A'PbOH: granular pp.

**Ethyl ether A'Et:** (255°), yellowish oil.

**Amide**  $C_{10}H_9ON_2CONH_2$ : [168°], slender needles (Schulz, B. 18, 2459).

**m-Carboxy-benzoyl-azoxim-benzoyl**

$C_6H_4(CO_2H).C \begin{smallmatrix} N.O \\ \diagup \diagdown \end{smallmatrix} C.C_6H_5$ . [218°]. Formed by heating benzamidoxim *m*-carboxylic acid with benzoyl chloride. White crystalline powder. Soluble in acetic acid, alcohol, and ether, insoluble in water and benzene. The aqueous solution of the ammonium salt gives pps. with  $AgNO_3$  and  $CuSO_4$  (Müller, B. 19, 1497).

**m-Carboxy-benzoyl-azoxim-ethenyl**

$C_6H_4(CO_2H).C \begin{smallmatrix} N.O \\ \diagup \diagdown \end{smallmatrix} C.CH_2$ . [217°]. Formed by heating benzamidoxim *m*-carboxylic acid with acetic anhydride. White crystalline powder. Sol. alcohol and ether, sl. sol. water and benzene. The aqueous solution of the ammonium salt gives pps. with  $AgNO_3$ ,  $CuSO_4$ ,  $Pb(OAc)_2$ , and  $ZnSO_4$  (Müller, B. 19, 1496).

**p-Carboxy-benzoyl-azoxim-ethenyl**

$C_6H_4N_2O_2$  i.e.  $C_6H_4(CO_2H).C \begin{smallmatrix} N.O \\ \diagup \diagdown \end{smallmatrix} C.CH_2$ . [218°]. Formed by boiling benzamidoxim *p*-carboxylic acid with acetic anhydride. Crystalline solid. Soluble in hot water and alcohol, more sparingly in ether and chloroform. The dilute solution of the ammonium salt gives pps. with  $AgNO_3$ ,  $Pb(OAc)_2$ , and  $CuSO_4$  (Müller, B. 19, 1492).

**m-Carboxy-benzoyl-azoxim-propenyl-o-carboxylic acid**

$C_6H_4(CO_2H).C \begin{smallmatrix} (3) (1) \\ N.O \\ \diagup \diagdown \end{smallmatrix} C.CH_2.CH_2.CO_2H$ . [213°]. Formed by heating benzamidoxim *m*-carboxylic acid with succinic anhydride. Needles. Sol. hot water, v. sol. alcohol and ether, sl. sol. chloroform, insol. benzene. The aqueous solution of the ammonium salt gives sparingly soluble pps. with  $AgNO_3$ ,  $CuSO_4$ , and  $Pb(OAc)_2$  (Müller, B. 19, 1496).

**p-Carboxy-benzoyl-azoxim-propenyl-o-carboxylic acid**

$C_6H_4(CO_2H).C \begin{smallmatrix} (4) (1) \\ N.O \\ \diagup \diagdown \end{smallmatrix} C.CH_2.CH_2.CO_2H$ . Formed by heating benzamidoxim *p*-carboxylic acid with an excess of succinic anhydride. Sol. alcohol, sl. sol. water, v. sl. sol. ether, insol. benzene and chloroform. Carbonises at a high temperature without melting. The dilute aqueous

solution of the ammonium salt gives insoluble pps. with  $\text{CuSO}_4$  and  $\text{Pb}(\text{OAc})_2$ , pps. soluble in hot water with  $\text{ZnSO}_4$  and  $\text{AgNO}_3$  (Müller, *B.* 19, 1492).

**Ethenyl-azoxim-benzenyl**

$\text{C}_6\text{H}_5\text{CH}_2\text{C}(\text{N}=\text{O})\text{C}_6\text{H}_5$ . [57°]. Long white needles. Begins to sublime at 70°-80°. Easily volatile with steam. V. sol. alcohol, ether, and benzene, sl. sol. hot water, insol. cold water and ligroin. Formed by heating ethenyl-amidoxim hydrochloride with benzoyl chloride (Nordmann, *B.* 17, 2754).

**m-Nitro-benzenyl-azoxim-benzenyl**

$\text{C}_6\text{H}_4(\text{NO}_2)\text{C}(\text{N}=\text{O})\text{C}_6\text{H}_5$ . [160°]. Formed by the action of benzoyl chloride upon *m*-nitro-benz-amidoxim  $\text{C}_6\text{H}_4(\text{NO}_2)\text{C}(\text{NH}_2)\text{NOH}$  (Schöpf, *B.* 18, 1067). White needles. Sublimable. Sol. alcohol, ether, and benzene, insol. water and ligroin.

**m-Nitro-benzenyl-azoxim-ethenyl**

$\text{C}_6\text{H}_4(\text{NO}_2)\text{C}(\text{N}=\text{O})\text{C}_2\text{H}_5$ . [109°]. White needles. Sublimable. Formed by the action of acetic anhydride upon *m*-nitro-benz-amidoxim  $\text{C}_6\text{H}_4(\text{NO}_2)\text{C}(\text{NH}_2)\text{NOH}$  (Schöpf, *B.* 18, 1066).

**m-Oxy-benzenyl-azoxim-benzenyl**

$\text{C}_6\text{H}_4(\text{OH})\text{C}(\text{N}=\text{O})\text{C}_6\text{H}_5$ . [163°]. Formed by diazotising *m*-amido-benzenyl-azoxim-benzenyl and heating the aqueous solution. Yellow needles. Sublimable. Sol. alcohol, ether, and benzene, scarcely sol. water, insol. ligroin.

*Ethyl ether*  $\text{C}_6\text{H}_4\text{ON}(\text{OEt})$ : [71°]; fine felted crystals; soluble in alcohol (Schöpf, *B.* 18, 2475).

**Phenyl-allenyl-azoxim-benzenyl**

$\text{C}_6\text{H}_5\text{CH}:\text{CH}:\text{C}(\text{N}=\text{O})\text{C}_6\text{H}_5$ . [102°]. *Cinnamyl-azoxim-benzenyl*. Formed by elimination of  $\text{H}_2\text{O}$  from the benzoyl derivative of phenyl-acryl-amidoxim by heating it above its melting point or by boiling it with water (Wolff, *B.* 19, 1509). Very slender white needles. V. sol. alcohol, ether, chloroform, and benzene, v. sl. sol. cold water. Sparingly volatile with steam.

**Phenyl-allenyl-azoxim-ethenyl**

$\text{C}_6\text{H}_5\text{CH}:\text{CH}:\text{C}(\text{N}=\text{O})\text{C}_2\text{H}_5$ . [78°]. Sublimable. Colourless crystals. Formed by heating phenyl-acryl-amidoxim with acetic anhydride (Wolff, *B.* 19, 1509).

**Phenyl-allenyl-azoxim-propenyl- $\omega$ -carboxylic acid**

$\text{C}_6\text{H}_5\text{CH}:\text{CH}:\text{C}(\text{N}=\text{O})\text{C}_2\text{H}_4\text{CH}_2\text{CO}_2\text{H}$ . [114°]. Formed by heating phenyl-acryl-amidoxim with succinic anhydride (Wolff, *B.* 19, 1511). Long white glistening prisms. Sol. alcohol, ether, benzene, and hot water, sl. sol. ligroin.—A'Ag: white powder.

**Phenyl-ethenyl-azoxim-benzenyl**

$\text{C}_6\text{H}_5\text{CH}_2\text{C}(\text{N}=\text{O})\text{C}_6\text{H}_5$ . [82°]. Formed by boiling the benzoyl derivative of phenyl-acet-amidoxim with water for a long time (Knudsen, *B.* 18, 1070). White needles. Volatile with steam. V. sol. alcohol, ether, and benzene, insol. water.

**Phenyl-ethenyl-azoxim-ethenyl**

$\text{C}_6\text{H}_5\text{CH}_2\text{C}(\text{N}=\text{O})\text{C}_2\text{H}_5$ . (369°). Oil. Volatile with steam. Formed by boiling the acetyl derivative of phenyl-acet-amidoxim with water for a long time (Knudsen, *B.* 18, 1070).

**Phenyl-ethenyl-azoxim-propenyl- $\omega$ -carboxylic acid**

$\text{C}_6\text{H}_5\text{CH}_2\text{C}(\text{N}=\text{O})\text{C}_2\text{H}_4\text{CH}_2\text{CO}_2\text{H}$ . [60°].

Formed by fusing together phenyl-acet-amidoxim  $\text{C}_6\text{H}_5\text{CH}_2\text{C}(\text{NH}_2)\text{NOH}$  and succinic anhydride. Prismatic plates. V. sol. alcohol and ether, sl. sol. cold, water, m. sol. hot. It is a strong acid. Salts. —A'Ag: white pp. —A'Ca: bluish green pp. (Knudsen, *B.* 18, 2483).

**Phenyl-oxy-ethenyl-azoxim-ethenyl**

$\text{C}_6\text{H}_5\text{CH}(\text{OH})\text{C}(\text{N}=\text{O})\text{C}_2\text{H}_5$ . [65°]. Formed by heating the acetyl derivative of phenyl-oxy-acet-amidoxim  $\text{C}_6\text{H}_5\text{CH}(\text{OH})\text{C}(\text{NH}_2)\text{NOAc}$  with water for some time. Transparent needles. Distils undecomposed, and is volatile with steam. V. sol. alcohol, ether, and benzene, sl. sol. cold water.

**Acetyl derivative**

$\text{C}_6\text{H}_5\text{CH}(\text{OAc})\text{C}(\text{N}=\text{O})\text{C}_2\text{H}_5$ . [52°]; fine white needles; volatile with steam; sol. alcohol, ether, and hot water, nearly insol. cold water (Gross, *B.* 18, 1076).

**p-Toluenyl-azoxim-benzenyl  $\text{C}_6\text{H}_4\text{Me}$  i.e.**

$\text{C}_6\text{H}_4\text{MeC}(\text{N}=\text{O})\text{C}_6\text{H}_5$ . [103°]. Formed by heating the benzoyl derivative of *p*-tolu-amidoxim,  $\text{H}_2\text{O}$  being split off (Schubart, *B.* 19, 1490). Long slender white needles. V. sol. ether, benzene, and chloroform, sl. sol. hot water, insol. cold.

**AZOXYNES.**—Compounds whose molecular formula may be written  $\text{X}''\text{C}(\text{NH})\text{Y}''$ , such as

*Phenazoxine*  $\text{C}_8\text{H}_7\text{C}(\text{NH})\text{C}_8\text{H}_7$ , and

*Naphthazoxine*  $\text{C}_{10}\text{H}_7\text{C}(\text{NH})\text{C}_{10}\text{H}_7$ .

They may be formed:—(1) By heating aromatic imido-sulphides with copper oxide:

(2) By heating *o*-amido-phenols with *o*-di-oxy-compounds:  $\text{C}_6\text{H}_3(\text{OH})_2\text{C}(\text{NH})\text{C}_6\text{H}_3(\text{OH})_2 =$

(Bernthsen, *B.* 20, 942).

**AZOXY-COMPOUNDS**, compounds whose molecular formula may be represented by

$\text{X}-\text{N}(\text{O})-\text{N}-\text{X}$ . They are formed by treating nitro-compounds with alcoholic potash or sodium amalgam. They may be reduced to hydrazo-compounds,  $\text{X}-\text{NH}-\text{NH}-\text{X}$ , and finally to two molecules of an amine,  $\text{X}-\text{NH}_2$ . The products of nitration of azoxy-compounds

are often unsymmetrical,  $\text{X}-\text{N}(\text{O})-\text{N}-\text{Y}$ .

***p*-Aldehyde-benzene azoxy-*p*-aldehyde-benzene acid**

formed by reduction of nitro-*p*-aldehyde-benzoic acid with aqueous KCN. Colourless needles. V. sol. ether, alcohol, and chloroform, sl. sol. ligroin, nearly insol. water. Decomposes at about 280°. It gives the ordinary reactions of an aldehyde.

*Phenyl hydrazide*: small golden yellow prisms (Homolka a. Löw, B. 19, 1090).

***o*-Amido-benzene-*o*-azoxy-aniline*****Di-benzoyl derivative***

(C<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>)(C<sub>6</sub>H<sub>4</sub>N<sub>2</sub>O) [195°]. Prepared by acting on benzoyl-*o*-nitraniline dissolved in alcohol with zinc-dust and adding ammonia and platinum chloride. Bright yellow mass, insol. water, sl. sol. boiling alcohol (Mixer, Am. 6, 26).

***m*-Amido-benzene-*m*-azoxy-aniline** [c. 272°]

*Di-benzoyl derivative*.—Prepared by dissolving *m*-nitro-benzaniline in boiling alcohol and adding alcoholic ammonia and powdered zinc together with a trace of platinum. Very light powder with pale yellow colour. Insol. alcohol, ether, and benzene (Mixer, Am. 5, 5).

***p*-Amido-benzene-*p*-azoxy-aniline**

(C<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>)N<sub>2</sub>O [182°–184°]. Prepared by the action of potassium ethylate on its diacetyl derivative. Sol. alcohol, giving a red solution. Sl. sol. boiling water, from which it separates on cooling as a fibrous yellow mass (Mixer, Am. 5, 4).

*Di-acetyl derivative* (C<sub>6</sub>H<sub>4</sub>NHAc)<sub>2</sub>N<sub>2</sub>O [275°–278°]. Prepared by the action of powdered zinc and ammonia on *p*-nitro-acetanilide in alcoholic solution. Hair-like particles with light golden-yellow colour. Sl. sol. boiling alcohol.

***Di-benzoyl derivative***

(C<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>)(C<sub>6</sub>H<sub>4</sub>N<sub>2</sub>O) [310°]. Prepared by the action of zinc and ammonia on *p*-nitro-benzaniline. Light yellow colour. Insol. alcohol and water (Mixer, Am. 5, 284).

***o*-Amido-toluene-azoxy-*o*-toluidine**

[1:2:4] C<sub>6</sub>H<sub>4</sub>Me(NH<sub>2</sub>)N<sub>2</sub>O.C<sub>6</sub>H<sub>4</sub>Me(NH<sub>2</sub>) [4:1:2] *Azoxo-*o*-toluidine*. [168°]. From nitro-*o*-toluidine in alcoholic solution by sodium amalgam (Limpricht, B. 18, 1405; Graeff, A. 229, 344). Long orange silky needles (from alcohol), or yellow needles (from water). V. sol. alcohol, sl. sol. water. Converted by conc. H<sub>2</sub>SO<sub>4</sub> by molecular change, into amido-toluene-azo-amido-cresol.

*Salts*.—B" H<sub>2</sub>SO<sub>4</sub> aq; needles.—B" 2HCl.—B" H<sub>2</sub>Cl.PtCl<sub>6</sub>.—B" 2HBr.

***p*-Amido-toluene-azoxy-*p*-toluidine**

[1:4:2] C<sub>6</sub>H<sub>4</sub>Me(NH<sub>2</sub>)N<sub>2</sub>O.C<sub>6</sub>H<sub>4</sub>Me(NH<sub>2</sub>) [2:1:4] [148°]. Yellow needles. Sol. alcohol and hot water. Prepared by the action of sodium amalgam on an alcoholic solution of nitro-*p*-toluidine. —B" (HCl); sl. sol. water. —B" H<sub>2</sub>Cl.PtCl<sub>6</sub> (Buckney, B. 11, 1451).

***Benzoyl derivative***

C<sub>6</sub>H<sub>4</sub>Me(NH<sub>2</sub>)(C<sub>6</sub>H<sub>4</sub>N<sub>2</sub>O).C<sub>6</sub>H<sub>4</sub>Me(NH<sub>2</sub>)(C<sub>6</sub>H<sub>4</sub>N<sub>2</sub>O) [290°]. From C<sub>6</sub>H<sub>4</sub>Me(NH<sub>2</sub>)(NO<sub>2</sub>) [1:4:2] by treatment with zinc and ammonia (Mixer, Am. 5, 285). Light yellow substance, insol. water and alcohol.

***Benzene-*p*-azoxy-aniline***

C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)N<sub>2</sub>O.C<sub>6</sub>H<sub>4</sub> [189°]. S. 4–27 at 21°. Formed, together with benzene-azo-aniline, by

the action of ammonium sulphide on an alcoholic solution of benzene-azoxy-nitro-benzene (G. Schmidt, A. 122, 174; Z. [2] 5, 419). Large pale-yellow tables (from dilute alcohol). Sl. sol. hot water, v. sol. alcohol and ether. Reduced by tin and HCl to aniline and *p*-phenylene-diamine.

*Salts*.—B' HCl: silvery laminae, saponified by water.—B' H<sub>2</sub>PtCl<sub>6</sub>.

**Benzene-azoxy-benzene** C<sub>6</sub>H<sub>4</sub>N<sub>2</sub>O.C<sub>6</sub>H<sub>4</sub>. Mol. w. 198. [36°]. S. (alcohol) 17–5 at 16°.

*Formation*.—1. From nitro-benzene by the action of alcoholic KOH (Zinin, J. pr. 86, 98; Hasenack, B. 5, 364; Schmidt a. Schultz, A. 207, 828; Wilsing, A. 215, 228), or sodium-amalgam (Alexejeff, J. 1864, 525; Molchanoffsky, J. R. 1882, 350).—2. From aniline by oxidising with KMnO<sub>4</sub> (Glaser, Z. [2] 2, 808).—3. From benzene-azo-benzene by oxidising with CrO<sub>2</sub> (Petrieft, B. 6, 577).

*Preparation*.—1. By reducing nitro-benzene in alcoholic solution by means of sodium-amalgam. The yield is 87 p.c. of the theoretical (Molchanoffsky, J. R. 1882, 224; Zl. [2] 38, 551).—2. By boiling nitro-benzene with sodium methylate, prepared from methyl alcohol (250g.) and sodium (10 g.), the reaction being as follows:

(Klinger, B. 15, 865).

*Properties*.—Pale yellow trimetric needles; insol. water, sol. alcohol, and ether. Small quantities may be volatilised with steam.

*Reactions*.—1. When mixed with neutral substances (e.g. NaCl) and distilled it gives aniline, azo-benzene, and other products.—2. *Ammonium sulphide* has hardly any action upon it in the cold, but on warming it reduces it to hydrazo-benzene.—3. SnCl<sub>4</sub> and HCl reduce it to aniline, very little benzidine being formed (Schmidt a. Schultz, B. 12, 484).—4. Warm conc. H<sub>2</sub>SO<sub>4</sub> converts it into benzene-*p*-azophenol (Wallach a. Belli, B. 13, 525).—5. *Aniline hydrochloride* at 230° gives violaniline (v. Dechend a. Wiechelhaus, B. 8, 1614).—6. *Diphenylamine hydrochloride* heated with it gives triphenyl-violaniline (Girard a. Caventou, B. 12, 290).—7. Conc. HBr at 250° gives di-bromo-aniline (Sendzink, Z. [2] 6, 266); HI gives benzidine.—8. PBr<sub>3</sub> gives yellow crystals of C<sub>6</sub>H<sub>4</sub>N<sub>2</sub>Br<sub>2</sub>, which are converted by aqueous AgNO<sub>3</sub> into benzene-azo-benzene (Werigo, Z. [2] 6, 387).—9. PCl<sub>5</sub> added to an ethereal solution gives benzene-azo-benzene (Werigo, A. 165, 202).—10. *Sodium amalgam* gives hydrazo-benzene.—11. *Sulphurous acid* forms benzidine sulphate.—12. *Nitric acid* forms three benzene-azoxy-nitro-benzenes (q. v.) and also a tri-nitro-derivative C<sub>6</sub>H<sub>4</sub>(NO<sub>2</sub>)<sub>3</sub>N<sub>2</sub>O [152°] (G. Schmidt, Z. [2] 5, 431). This is converted by CrO<sub>3</sub> mixed with conc. HNO<sub>3</sub> at 200° into C<sub>6</sub>H<sub>4</sub>(NO<sub>2</sub>)<sub>3</sub>N<sub>2</sub>O [102°], and C<sub>6</sub>H<sub>4</sub>(NO<sub>2</sub>)<sub>3</sub>N<sub>2</sub>O [52°] (Petrieft, B. 6, 558).

**Benzene-azoxy-benzene-*m*-sulphonic acid** C<sub>6</sub>H<sub>4</sub>N<sub>2</sub>O.C<sub>6</sub>H<sub>4</sub>(SO<sub>3</sub>H). [60°–70°]. Very deliquescent reddish-brown tables. Formed as a by-product in the oxidation of *m*-amido-benzene-sulphonic acid by KMnO<sub>4</sub>.—KA' aq: long soluble tables (Limpricht, B. 18, 1420).

**Benzene-azoxy-benzene-*p*-sulphonic acid** C<sub>6</sub>H<sub>4</sub>N<sub>2</sub>O.C<sub>6</sub>H<sub>4</sub>(SO<sub>3</sub>H). [below 100°]. Red scales. V. sol. water. Formed as a by-product in the

oxidation of sulphamic acid by  $\text{KMnO}_4$ ; the yield is about 2 p.c.— $\text{KA}'2\text{aq}$ : small yellow crystals (Limpricht, *B.* 18, 1420).

**Benzene-azoxy-bromo-benzene sulphonic acid**  $\text{C}_6\text{H}_4\text{N}_2\text{O}_2\text{C}_6\text{H}_4\text{Br}(\text{SO}_3\text{H})$ . Formed as a by-product of the oxidation of bromo-amido-benzene-sulphonic acid  $\text{C}_6\text{H}_4\text{Br}(\text{NH}_2)(\text{SO}_3\text{H})$  (4:3:1) with  $\text{KMnO}_4$ — $\text{KA}'2\text{aq}$ : small red six-sided tables (Limpricht, *B.* 18, 1423). V. sol. water and alcohol.

**Benzene-*p*-azoxy-nitro-benzene**  $\text{C}_6\text{H}_4\text{N}_2\text{O}_2\text{C}_6\text{H}_4\text{NO}_2$  [1:4]. [153°]. Formed together with the following body by the action of  $\text{HNO}_3$  (S.G. 1.45) on benzene-azoxy-benzene (Zinin, *A.* 114, 218). Hair-like yellow needles. Reduced by alcoholic ammonium sulphide to benzene-*p*-azoxy-aniline.

**Benzene-azoxy-nitro-benzene**  $\text{C}_6\text{H}_4\text{N}_2\text{O}_2\text{C}_6\text{H}_4\text{NO}_2$  [49°]. Needles or prisms; prepared as above. Alcoholic ammonium sulphide forms a compound  $\text{C}_{12}\text{H}_{10}\text{N}_4\text{O}_4$  (?) [85°].

**Benzene-azoxy-nitro-benzene**  $\text{C}_6\text{H}_4\text{N}_2\text{O}_2\text{C}_6\text{H}_4(\text{NO}_2)$  [1:2]. [127°]. Formed by adding fuming  $\text{HNO}_3$  (25.30 c.c.) to a solution of benzene-azo-benzene (20 g.) in glacial acetic acid (100 c.c.) at 75°. Red rhombic plates. Sol. alcohol, ether, and acetone. Alcoholic KOH gives an emerald-green colouration; by long boiling or by treatment with sodium-amalgam it is reduced to a compound  $\text{C}_{12}\text{H}_{10}\text{N}_4\text{O}_2$  (Janovsky *A.* Erb, *B.* 20, 361).

**Benzoic *o*-azoxy-benzoic acid**  $(2:1) \text{C}_6\text{H}_4(\text{CO}_2\text{H})-\text{N}_2\text{O}-\text{C}_6\text{H}_4(\text{CO}_2\text{H})$  [1:2]. Mol. w. 246. [237°-212°].

**Formation**.—1. By the action of KCN on *o*-nitro-benzaldehyde (Homolka, *B.* 17, 1902).—2. From *o*-nitro-benzoic acid by treatment with sodium-amalgam or alcoholic KOH (Grüss, *B.* 7, 1611).—3. Together with *o*-nitro-toluene by boiling *o*-nitro-benzyl alcohol with aqueous KOH (Jaffé, *H.* 2, 57).

**Properties**.—Small colourless prisms; m. sol. hot alcohol, sl. sol. ether and boiling water. Reduced by sodium-amalgam to carboxy-benzene-azo-benzoic acid, and finally to hydrazo-benzoic acid.

**Salt**.— $\text{BaA}'$  4aq.

**Benzoic *m*-azoxy-benzoic acid**  $(3:1) \text{C}_6\text{H}_4(\text{CO}_2\text{H})-\text{N}_2\text{O}-\text{C}_6\text{H}_4(\text{CO}_2\text{H})$  [1:3]. Formed by boiling *m*-nitro-benzoic acid with alcoholic KOH (Grüss, *A.* 131, 92). Minute needles or plates. Insol. water, sl. sol. alcohol and ether. Reduced by tin and HCl to di-amido-diphenic acid.

**Diazoxy-benzoic acid**

Formed by reducing di-nitro-benzoic acid dissolved in  $\text{NaOHAq}$  with sodium-amalgam (V. Meyer *A.* Michler, *B.* 6, 746; Michler, *B.* 7, 430; *A.* 175, 150). An amorphous black powder, insol. alcohol, ether, benzene, chloroform, and glacial acetic acid. Reduced by tin and HCl to diamido-benzoic acid.  $\text{HNO}_3$  gives an amorphous nitro-derivative.

**Salts**.— $\text{AgA}'$ : black pp. sol.  $\text{NH}_4\text{Aq}$ .— $\text{BaA}'$ : black pp.— $\text{ZnA}'$ : brownish-black pp.

An isomeric acid, resembling the above, is formed from (1, 2, 4)-di-nitro-benzoic acid. It is not attacked by tin and HCl.

***m*-Bromo-benzene-*m*-azoxy-bromo-benzene**  $(4:1) \text{C}_6\text{H}_3\text{Br} \cdot \text{N}_2\text{O}_2 \cdot \text{C}_6\text{H}_3\text{Br}$  [1:3]. [115°]. From *m*-bromo-nitro-benzene and alcoholic KOH (Gabriel, *B.* 9, 1408). Bright yellow prisms; v. sl. sol. alcohol.

***p*-Bromo-benzene-*p*-azoxy-bromo-benzene**  $(4:1) \text{C}_6\text{H}_3\text{Br} \cdot \text{N}_2\text{O}_2 \cdot \text{C}_6\text{H}_3\text{Br}$  [1:4]. [179°] (Hofmann *A.* Geyger, *B.* 5, 919); [175°] (Werigo, *A.* 165, 198). From *p*-bromo-nitro-benzene by treatment with alcoholic KOH or sodium-amalgam. Yellow leaflets, v. sol. hot alcohol. Nitric acid forms a tri-nitro-derivative [174°].

**Bromo-benzene-azoxy-bromo-benzene sulphonic acid**  $\text{C}_6\text{H}_3\text{Br} \cdot \text{N}_2\text{O}_2 \cdot \text{C}_6\text{H}_3\text{Br}(\text{SO}_3\text{H})$ . Formed as a by-product of the oxidation of di-bromo-amido-benzene-sulphonic acid  $\text{C}_6\text{H}_3\text{Br}(\text{NH}_2)(\text{SO}_3\text{H})$  [1:3:6:4] by  $\text{KMnO}_4$ — $\text{KA}'2\text{aq}$ : very small yellow scales (Limpricht, *B.* 18, 1425).

***m*-Chloro-benzene-*m*-azoxy-chloro-benzene**  $(3:1) \text{C}_6\text{H}_3\text{Cl} \cdot \text{N}_2\text{O}_2 \cdot \text{C}_6\text{H}_3\text{Cl}$  [1:3]. [97°]. Formed by boiling *m*-chloro-nitro-benzene with alcoholic KOH (Laubenheimer *A.* Winther, *B.* 8, 1623). Yellowish-brown flat needles. V. sl. sol. alcohol. Treated with fuming  $\text{H}_2\text{SO}_4$  it is chiefly converted into *m*-chloro-benzene-azo-chloro-phenol, only a very small quantity of *m*-chloro-benzene-azo-chloro-benzene being formed (Schultz, *B.* 17, 464).

***p*-Chloro-benzene-azoxy-chloro-benzene**  $(4:1) \text{C}_6\text{H}_3\text{Cl} \cdot \text{N}_2\text{O}_2 \cdot \text{C}_6\text{H}_3\text{Cl}$  [1:4]. [165°]. From *p*-chloro-nitro-benzene by treatment with alcoholic KOH (Heumann, *B.* 5, 910; cf. Willgerodt, *B.* 15, 1002), sodium-amalgam (Alexejeff, *Z.* 1866, 269), or (in ethereal solution) with sodium (Hofmann *A.* Geyger, *B.* 5, 916). Pale yellow needles, sl. sol. cold alcohol. Treated with fuming  $\text{H}_2\text{SO}_4$  it is chiefly converted into *p*-chloro-benzene-azo-chloro-benzene only forming traces of a chlorinated benzene-azo-phenol (Schultz, *B.* 17, 464).

**Di-chloro-benzene-azoxy-di-chloro-benzene**  $(3:5:1) \text{C}_6\text{H}_3\text{Cl}_2 \cdot \text{N}_2\text{O}_2 \cdot \text{C}_6\text{H}_3\text{Cl}_2$  [1:3:5]. [172°]. From (3,5,1)-di-chloro-nitro-benzene and alcoholic KHS (Beilstein *A.* Kurbatow, *A.* 197, 84).

**Di-chloro-benzene-azoxy-di-chloro-benzene**  $(2:5:1) \text{C}_6\text{H}_3\text{Cl}_2 \cdot \text{N}_2\text{O}_2 \cdot \text{C}_6\text{H}_3\text{Cl}_2$  [1:2:5]. [112°]. From *p*-di-chloro-nitro-benzene and alcoholic KOH (Laubenheimer, *B.* 7, 1600; 8, 1623). Small bright yellow needles.

***p*-Chloro-benzene-azoxy-chloro-nitro-benzene**  $(4:1) \text{C}_6\text{H}_3\text{Cl} \cdot \text{N}_2\text{O}_2 \cdot \text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)$  [1:4:1]. [184°]. From *p*-chloro-benzene-*p*-azoxy-chloro-benzene and  $\text{HNO}_3$  (Heumann, *B.* 5, 912; 18, 1185). Bright yellow flocculent substance. V. sl. sol. boiling alcohol; reduced by alcoholic ammonium sulphide to *p*-chloro-benzene-azo-chloro-nitro-benzene.

**Chloro-toluene-azoxy-chloro-toluene**  $(6:3:1) \text{C}_6\text{H}_3\text{MeCl} \cdot \text{N}_2\text{O}_2 \cdot \text{C}_6\text{H}_3\text{MeCl}$  [1:3:3]. [128°]. Formed by the action of Na on an ethereal solution of chloro-nitro-toluene (Hofmann *A.* Geyger, *B.* 5, 919). Small needles.

***m*-Iodo-benzene-*m*-azoxy-iodo-benzene**  $(3:1) \text{C}_6\text{H}_3\text{I} \cdot \text{N}_2\text{O}_2 \cdot \text{C}_6\text{H}_3\text{I}$  [1:3]. From *m*-iodo-nitro-benzene and alcoholic KOH (Gabriel, *B.* 9, 1408). Flat yellow needles; sl. sol. cold alcohol.

***p*-Iodo-benzene-*p*-azoxy-iodo-benzene**  $(4:1) \text{C}_6\text{H}_3\text{I} \cdot \text{N}_2\text{O}_2 \cdot \text{C}_6\text{H}_3\text{I}$  [1:4]. [200°]. From *p*-iodo-nitro-benzene and alcoholic KOH (G.). Light yellow plates or scales. Sl. sol. hot alcohol.

**N-methyl-amido-benzene-azoxy-di-methyl-aniline** [4:1]  $C_6H_5NMe_2 \cdot N_2O \cdot C_6H_4NMe_2$ , [1:4]. From *p*-nitroso-di-methyl-aniline and alcoholic KOH (Schraube, B. 8, 619). Glittering brown crystals; sl. sol. water, m. sol. hot alcohol and benzene. The salts are decomposed by water. —B'H.P.C.I., aq.

**m-Nitro-benzene-m-azoxy-nitro-benzene** [3:1]  $C_6H_4(NO_2) \cdot N_2O \cdot C_6H_4(NO_2)$ , [1:3] [142°].

**Preparation.**—A solution of 2 or 3 pts. of *m*-di-nitrobenzene in about 15 pts. of methyl alcohol is mixed with a solution of sodium methyrate prepared by dissolving 1 pt. of sodium in 20 pts. of methyl alcohol. A vigorous reaction sets in, which is completed by 48 hrs. cohabitation; large yield. Long needles. V. sol. benzene, m. sol. ether and  $CS_2$ , v. sl. sol. cold alcohol. By heating to about 140° with strong  $H_2SO_4$  it is converted into the isomeric di-nitro-*oxy*-azo-benzene  $C_6H_4(NO_2) \cdot N_2 \cdot C_6H_4(NO_2)(OH)$  (Klinger a. Pitschke, B. 18, 2551).

**p-Nitro-diphenyl-p-azoxy-nitro-diphenyl**  $C_6H_4(NO_2) \cdot C_6H_4 \cdot N_2O \cdot C_6H_4 \cdot C_6H_4NO_2$ , [225°]. From *p*-di-nitro-diphenyl by acting on its alcoholic solution with sodium-amalgam (Wald, B. 10, 137). Brick-red crystalline powder; forms a red solution in conc.  $H_2SO_4$ . Insol. most solvents. Reduced by alcoholic ammonium sulphide to benzidine.

**Nitro-*oxy*-benzene-azoxy-di-nitro-phenol**

**Diethyl ether**

$C_6H_4(NO_2)(OEt) \cdot N_2O \cdot C_6H_4(NO_2) \cdot OEt$ , [168°]. From  $HNO_3$  and the diethyl ether of *p*-oxy-benzene-*p*-azo-phenol: the product is exhausted with water, and then treated with alcohol. On cooling, the alcohol deposits the body in long yellow needles grouped in stars. Sol. ether,  $CHCl_3$ ,  $C_6H_6$  and glacial acetic acid (Andreae, J. pr. 129, 337).

**An isomeric body.** [187°]. This forms the greater part of the product of the nitration, and is left undissolved when the former body is extracted with alcohol. It is crystallised from acetic ether, in which it is very soluble.

**o-Oxy-benzene-o-azoxy-phenol**

$C_6H_4(OH) \cdot N_2O \cdot C_6H_4 \cdot OH$

**Ethyl ether**  $\{C_6H_4(OEt)\}_2 \cdot N_2O$ . **Azoxy-phenol.** [102°]. By reducing a cold (0°) solution of *o*-nitro-phenol (1 pt.) in alcohol (7 pts.) by adding sodium amalgam; on adding water a pp. is got; this is freed from azo-phenol by washing with strong HCl as long as the latter is coloured (Schmitt a. Mühlau, J. pr. 126, 201).

**Properties.**—Colourless triclinic plates. Insoluble in water, but melts in boiling water. Slightly soluble in cold alcohol, insoluble in hot alcohol. Not volatile with steam.

**Diphenyl-azoxy-diphenyl**

$C_6H_5 \cdot C_6H_4 \cdot N_2O \cdot C_6H_4 \cdot C_6H_5$ , [205°]. Small yellow plates. Insol. water and alcohol, sl. sol. acetic acid. Prepared by the action of alcoholic KOH on *p*-nitro-di-phenyl (Zimmermann, B. 13, 1961).

**Phenyl-glycollic-o-azoxy-phenyl-glycollic acid**  $ON_2C_6H_4 \cdot CH(OH) \cdot CO_2H$ , [187°].

**Preparation.**—*o*-Nitro-phenyl glycollic acid (18.6 g), water (140 g.) and  $Na_2CO_3$  (5 g.) are treated at 55° with sodium-amalgam (165 g. of 4 per cent. sodium), added in small portions. On cooling, crystals separate. These are dissolved in water and decomposed by HCl.

The precipitated acids are recrystallised from alcohol. If the mixed acids now melt above 162°, they are etherified by alcohol and HCl. The ether of the azoxy-acid is less soluble in alcohol than that of the azo-acid, it is crystallised from alcohol and then saponified (A. Thate, J. pr. [2] 29, 152).

**Properties.**—Crystallises, from aqueous or dilute alcoholic solutions, with aq. as short prisms or as scalenohedra; but if left in contact with the mother liquor these change to rhombohedra, taking up aq. Both these forms are sulphur-yellow. At 130° they become white and anhydrous. Dissolves in alkalis, HCl and glacial acetic acid. The solutions are yellow. Forms red solutions with  $HNO_3$  and  $H_2SO_4$ . Insoluble in ether and in benzene.

**Reactions.**—1. **Lead acetate**, a yellowish-white flocculent pp.—2.  $AgNO_3$  and  $BaCl_2$ , no pp. in hot solutions, on cooling a crystalline pp.

**Salts.**— $(NH_4)_2A''$ : obtained, as a yellow micro-crystalline pp., by passing  $NH_3$  into a solution of the acid in absolute alcohol. Its aqueous solution gives yellowish-white pps. with  $BaCl_2$  and  $Pb(OAc)_2$ , yellow pps. with  $AgNO_3$  and  $FeCl_3$ , and a green pp. with  $CuSO_4$ .— $Ag_2A'$ .— $AgHA'$ : more soluble than the neutral salt.  $BaA''$  2aq.

**Ethyl ether.**— $Et_2A'$ ; [114°]. White silky needles.

**m-Sulpho-benzene-m-azoxy-benzene sulphonic acid** [3:1]  $C_6H_4(HSO_3) \cdot N_2O \cdot C_6H_4(HSO_3)$ , [1:3], [125°]. Prepared by the reduction of *m*-nitro-benzene-sulphonic acid with alcoholic KOH (Brunnemann, B. 11, 1048; A. 202, 240). Yellow needles. V. sol. water and spirit.

$A''K_4$  4aq: needles.— $A''(NH_4)_2$  2aq: rhombic pillars.— $A''Ba$  aq: difficultly soluble prisms.  $A''Ca$  3aq: difficultly soluble needles.— $A''Tb$  aq.

**Chloride** [138°]. Yellowish-red pillars.

**Amide** [273°]: sl. sol. hot water.

**Sulpho-naphthalene-azoxy-naphthalene sulphonic acid**  $C_{10}H_6(SO_3H) \cdot N_2O \cdot C_{10}H_6 \cdot SO_3H$ . From (a)-nitro-naphthalene-(a)-sulphonic acid and alcoholic KOH (Allen, B. [2] 45, 184). V. sol. water; conc.  $H_2SO_4$  forms a violet solution.

**Salts.**— $K_2A'$  aq: trimetric tabular crystals.  $Na_2A''$  2aq: tables.— $BaA'$  aq.— $CaA'$  2aq.— $PbA'$  2aq.

**Terephthalic-azoxy-terephthalic acid**

[6:3:1]  $C_6H_4(CO_2H) \cdot N_2O \cdot C_6H_4(CO_2H)$ , [1:6:3]. Yellowish plates. Sol. hot, sl. sol. cold, water, v. sol. alcohol and ether. Decomposes between 250° and 280°. Obtained by oxidation of aldehyde-benzoic-azoxy-aldehyde-benzoic acid  $N_2O(C_6H_4(CHO)CO_2H)_2$  with alkaline  $KMnO_4$ .

**Salts.**— $A''(NH_4)_2$ : long yellowish prisms.  $A''Ag$ : yellow pp. (Hofmalka a. Löw, B. 19, 1091).

**Toluene-azoxy-bromo-toluene**

$C_6H_4Me \cdot N_2O \cdot C_6H_4Br$ , [74°]. From *p*-toluene-*p*-azoxy-toluene and bromine. Bright yellow tables; v. sol. alcohol and ether (Melms, B. 3, 551).

**Toluene-azoxy-nitro-toluene**

$C_6H_4Me \cdot N_2O \cdot C_6H_4(NO_2)Me$ , [84°]. Formed by nitration of *p*-toluene-*p*-azoxy-toluene (Patrieff, B. 6, 557). Yellow needles.

**Toluene-o-azoxy-toluene**

$C_6H_4(CH_3) \cdot N_2O \cdot C_6H_4(CH_3)$ , [60°]. Formed by passing  $Cl_2O$  into an ethereal solution of *o*-hydrazo-toluene (Patrieff, B. 6, 557).

**Preparation.**—10 pts. of *o*-nitro-toluene are

added gradually to a solution of 5 pts. of sodium in 50 pts. by volume of methyl alcohol, the mixture being finally cohobated on the water-bath for 3 or 4 hours.

**Properties.**—Large yellow needles or plates; the crystals belong to the dimetric system,  $\alpha:b = 84:10:1$ .

**Reactions.**—By distillation with iron powder it yields *o*-azotoluene and a little toluidine. It also yields *o*-azotoluene by heating with  $H_2SO_4$  (Klinger & Pitschke, *B.* 18, 2553).

***p*-Toluene-*p*-azoxy-toluene**  
 $C_6H_5Me.N_2O.C_6H_5Me$ . [70°] (M.); [59°] (P.). From *p*-nitro-toluene by reducing it in alcoholic solution with sodium amalgam (Melms, *B.* 3, 551; Petrieff, *Z.* [2] 5, 264; [2] 6, 30; *D.* 6, 557). V. sol. alcohol and ether.

**Bromine** gives a bromo-derivative, [74°], and a di-bromo-derivative [139°].

**Nitric acid** gives a nitro-derivative [84°], a di-nitro-derivative [145°], and a tri-nitro-derivative [201°].

**AZOXYLENE** v. *Xylene-azo-xylene*.

**AZOXY-NAPHTHALENE** v. Naphthalene-azoxy-naphthalene.

**AZOXY-PHENOL** v. Oxy-benzene-azoxy-phenol.

**AZOXY-DIPHENYL** v. Diphenyl-azoxy-diphenyl.

**AZOXY-TOLUENE** v. Toluene-azoxy-toluene.

**AZULENE** or **Azulin**. Blue colouring matter present in essential oils of chamomile, wormwood, and millefolium. Causes these and other oils to give an absorption-spectrum, viz., three bands in red and orange (Hock, *Ar. Ph.* [3] 21, 17).

**AZULMIC ACID**  $C_6H_5N_2O$ . Fluoresces brown pp. formed together with oxamide as oxamic acid by passing cyanogen into aqueous ammonia. Sl. sol. pure water, with violet fluorescence; acid or alkaline solutions fluoresce green. Boiling water slowly converts it into mycomelic acid  $C_6H_5N_2O_2$ . Nitric acid or  $KMnO_4$  oxidises it to azulmoxin  $C_6H_5N_2O_3$ , an orange powder, insol. water, sol. conc.  $H_2SO_4$ , the solution having a deep-green fluorescence.

**Hydrazulinia**  $C_6H_5N_2$  is formed by mixing dry cyanogen with dry  $NH_3$ . It forms black leaflets, converted by water at once into  $NH_3$  and azulmic acid (Emmoring & Jacobsen, *B.* 4, 927). By the spontaneous decomposition of an aqueous solution of HCN containing a little  $NH_3$ , a brown pp. is produced which, according to Gautier (*A. Ch.* [4] 17, 159), contains an azulmic acid of the formula  $C_6H_5N_2O$ .

**AZURIN**  $C_6H_5N_2O$ . [250-5°]. Small colourless tables forming solutions which have a splendid blue fluorescence. Prepared by heating salicylic aldehyde with *o*-tolylene-diamine (Ladenburg, *B.* 11, 590).

**AZYLINES**. Azo-compounds of the form  $R_1N.O.H.N:N.O.H.NR_2$  prepared by passing nitric oxide into alcoholic solutions of tertiary aromatic amines; thus, di-methyl-aniline-azylene is described as di-methyl-amido-benzene-azo-di-methyl-aniline, di-aryl-aniline-azylene is described as di-aryl-amido-benzene-azo-di-aryl-aniline; and di-ethyl-aniline-azylene as di-ethyl-amido-benzene-azo-di-ethyl-aniline (Lippmann & Fleisner, *M.* 3, 705; 4, 284, 788; *B.* 15, 2130; 16, 1421; Nölting, *B.* 18, 1143).

## B

**BABLAH.** The fruit of several species of *Acacia*. The seeds and husks are rich in tannin.

**BACCARINE.** An alkaloid in *Baccharis cordifolia* or 'Mio-Mio.' Needles, al. sol. water, sol. alcohol, amyl alcohol, and ether. Its aqueous solution is neutral to litmus (Arata, *P.A.* [3] 10, 6).

**BACTERIA.**—The name given originally to a common root-like form which is assumed in the course of growth by the minute plants to which Nägeli (6) in 1857 applied the term *Schizomycetes*; hence the term 'Bacteria' is very frequently used to designate the whole of this group of organisms.

The Bacteria, Bacteriaceae, or Schizomycetes are a group of plants of extreme simplicity of structure and very minute in size. Like larger fungi, they are destitute of chlorophyll, and accordingly are unable to decompose carbonic acid in the presence of sunlight; as a consequence their nutrition resembles in some respects that of animals, since they are dependent on the complex chemical substances produced by other organisms. The variety of substances containing either C or N, or both, which they can attack and make contributory to their sus-

tenance is very great, whilst the chemical changes which they bring about in these substances are no less varied and remarkable. The exact nature of these changes and the relation of the Bacteria themselves to the substances upon which they feed form an enormous field of inquiry which has only recently been looked at by chemists, and that, as yet, very cursorily. The study of the forms presented by different kinds of Bacteria in the course of their growth is also as yet in an incomplete state, and whilst it is certain that there are kinds of Bacteria characterised each by its particular form, its particular pabulum or chemical food, and by its particular chemical operations resulting in the formation of definite chemical products from the breaking up of the appropriate pabulum, we do not yet know in any large number of cases whether a particular form is constantly associated with particular chemical conditions and results, or whether it is possible under modified conditions for a given form to change its chemical and physiological activities. In a certain number of cases we do know that modified chemical and physical conditions will cause a given form in the course of its growth to acquire a very marked modification of form. Hence it is at present im-

possible to discriminate with accuracy different 'species' of Bacteria, although botanists use particular names to designate those which, so far as our information yet goes, are characterised by the constancy of a certain range of form, or in addition to this, by the constancy of chemical and physiological activity. By 'species' the naturalist understands a group of organic forms the members of which may present very little or very great differences of form and even of activities as compared one with another, but of which it is true, either that they actually are connected with one another by natural processes of reproduction which have occurred within human experience and observation, or that there is good reason to suppose that they might be so connected within human experience. Forms which are separated from one another by an interval the passage of which has not been witnessed and recorded by observers in the past, or defies experiment at the present day, are distinct species. We have not by experimental breeding produced a horse from an ass or an ass from a horse, or both from a third form, and we have no record of observations leading to the inference that such a passage has occurred within human experience, hence the horse and the ass are distinct species. On the other hand, we have traditional and experimental evidence of the production of the varieties of fancy pigeons from the Rock Pigeon, and conversely we know that from the most fantastic of fancy pigeons the Rock Pigeon can be produced in the course of a few generations: hence the Rock Pigeon and the Tumbler, Pouter, Fantail, Carrier, &c., are all variously modified members of one species.

It is necessary to allude to the question of species here because the progress of our knowledge of Bacteria in the immediate past has consisted in an important degree in the recognition of the fact that a great variety of microscopic forms may belong to one and the same species of Bacterium, and because we have to expect the most important advances in the future from the endeavours of bacteriologists experimentally to breed by change of conditions one kind of Bacterium from another, and even to create experimentally new kinds; and this in spite of the fact that it has been unjustifiably assumed that the forms of Bacteria at present recognised are of the nature of species and immutable.

**Classificatory position of Bacteria.**—The nearest allies of the Bacteria among chlorophyll-bearing plants are the Oscillatoria and certain green-coloured organisms (the so-called *B. chlorinum*, *B. virens*, *B. viride*) which, whilst identical in form with some of the Bacteria, differ physiologically from them in possessing chlorophyll. The distinction between these plants and the Bacteria is not by any means a wide one, and there can be no doubt of the close genetic relationship of the green and the greenless Schizophyta, the Bacteria having, as is the case in other groups of plants, lost their chlorophyll and acquired parasitic or saprophytic (refuse-eating) habits *pari passu*.

**Forms of Bacteria.**—The Bacteria present themselves either as swarming accumulations of detached cells or as linear aggregates (filaments or chains) of cells. Frequently the cells or

embodies in a jelly, so as to form sheets or massive aggregations. The individual cells are usually extremely minute, being only .001 mm. or even less in diameter, though they may be larger. The cells consist of a homogeneous protoplasm in which no nucleus can be detected; a cell wall, sometimes extremely delicate, bounds the surface of the cell, consisting of 'mycoprotein,' rarely of cellulose. When the cell-wall swells up, imbibing water, a jelly is formed in which the cells are set at intervals ('zoogloea' condition). The ultimate shape of the cells of the Bacteria varies: it may be spherical (coccus-form or micrococcus), biscuit-shaped or keyhole-shaped, like two spheres partially fused (clithridium-form or bacterium *sensu stricto*), cuboid, varying from a cube to a short prism (microbacillus form), rod-shaped (bacillus-form), curved like a bent rod (comma-form), twisted like a fraction of a corkscrew (spirillum-form; if the spiral is not strongly marked, vibrio-form). The most characteristic feature of these cells is their power of rapid growth and multiplication by fission into two equal portions. Brefeld has observed a Bacterium, formed by fission, grow to the size of the parent cell and itself divide into two in the course of half an hour, each of the daughter cells repeating the process in half an hour. In the course of 24 hours there are thus produced from a single Bacterium more than a billion individuals like itself. The constant and rapid process of binary fission is what has led to the use of the names Schizophyta and Schizomycetes. All the forms of cells which we have enumerated as being assumed by Bacteria exhibit this phenomenon. But it is not necessary that the results of the fission should separate entirely from one another. Frequently such separation occurs, and in the forms known as clithridium (or bacterium *sensu stricto*) bacillus, vibrio, and spirillum, a filament of naked protoplasm is frequently observed hanging from each end of the fission-product, and by its lashing movements causes an active 'swarming' movement, or darting progression of the separate cells. Contrasted with this locomotive swarming phase we have to note the phase of aggregation or continuous growth. As the result of variation in their pabulum, Bacteria which were at one hour separating from one another after fission—may remain in the next hour of growth in contact—held by their unruptured cell-walls. Thus are produced, in place of motile swarming individual cells, aggregates or colonies which may be (1) linear; (2) tessellate; (3) branched; (4) retiform; (5) massive. Any of these forms of aggregation may be exhibited by any of the different forms of cells. Linear aggregates of micrococci are called rosary-chains or streptococcus; linear aggregates of micro-bacilli form longer bacilli and so-called leptothrix filaments; linear aggregates of comma-shaped segments form spirilla; and small spirilla and vibrios when aggregated end to end form larger spirilla. Branched aggregation is seen in the so-called *Cladothrix dichotoma*, where a leptothrix filament breaks so as to allow a new line of growth to start at the broken surface, but without separation of the original continuation of the filament which takes up a lateral position as a 'follower'.

branch (fig. 3). Similarly mesh-works (resembling those of the green hydrodictyon) are produced (fig. 7), and very regular tessellate aggregates (fig. 9). In the latter, bacillus or ciliatidium forms may be arranged with absolute symmetry forming little plates of twenty or more cells, in rows of five or more (merismopodia form). In the sarcina form the grouping is cuboid, 'packets' being produced instead of

FORMS OF BACTERIA. a. Micrococcus; b. Diplococcus; c. Ciliatidium or biscuit (with flagella); d. Microbacillus; e. Bacillus (built up of microbacilli); f. Leptothrix or filamentous form, homogeneous at one end, divided into bacilli in the middle and into microbacilli at the other end; g. Spirillum (vibrio); h. Spirillum (close spiral) with flagella; i. Gomma (segment of spirillum); j. Homogeneous bacillus with flagella; k. Uroid or double-rod form; m. Large irregular form: these may occur of great size and various shapes, as flat discs (macroplasts) in *Bact. rubescens*.—Zent.: n. Bacillus with moniliform protoplasm, not spores (*B. tuberculosis*); o. Sporobacillus, with endospores; p. Rosary-chain; linear aggregate of micrococci; q. Merismopodia-form or tablet; tessellate aggregate of ciliatidia; r. Hydrodictyon-form: retiform aggregate of bacilli; s. Chloothrix-form: false-branched linear aggregate of bacilli; t. Nostocoid linear aggregate; larger cocci occur at intervals in a chain of smaller cocci observed in cultivation of *B. anthracis*; u. Two micrococci embedded in jelly-like envelope; v. Leuconostoc-form: a spirillum with jelly-like envelope; x. Zooglia of ciliatidia: ciliatidia embedded in jelly-like matrix.

'plates.' Lastly, where the cell-wall swells up and forms a jelly, we may have the bacterian cells of any one shape adhering by the jelly to one another (fig. 2), and forming spherical or irregular masses of jelly (zooglia). These masses often are as large as the hand of a man, and are found on putrefying liquids and solids.

There is no doubt that all the forms of cell and of cell-aggregates which have been above

described, and others to boot, may be exhibited by one and the same species of Bacterium. The *Bacterium rubescens* of Lankester [1] forms portwine coloured pellicles on decaying organic matter in fresh-water ponds and in salt-marshes, the protoplasm of the cells being coloured by a peculiar insoluble pigment 'bacterio-purpurin.' Lankester found all the varieties of aggregation and of cell-form (except spirilla, since observed by Warming [2] and by Giard [3]), in a small tank in which this organism was flourishing; their connection with one another was proved by their all containing the peculiar colouring matter and by transition-forms of growth. The accuracy of these observations has been confirmed by Zopf [4], and Lankester's conclusions adopted by him as well as by De Bary [5]. The species of Bacteria are said to be 'pleomorphic' or in Lankester's phraseology 'protean.' Nevertheless it is exceedingly probable that not all bacterian species exhibit so wide a range of form as does *B. rubescens*. Some seem to be limited to the micrococcus and ciliatidium cell-forms, and to exist either as free swarming cells of those shapes, or as linear aggregates of the same. Others again are possibly limited to the micrococcus form, though it is necessarily extremely difficult to be sure that under appropriate conditions of cultivation the cell-form and aggregation-form will not change altogether, and, until experiments have been very carefully made in each case with the object of breaking down the limitation of form usual to this or that species of Bacterium, it will not be justifiable to dogmatically characterise a species of Bacterium by reference to its shape.

**Spore-formation.** The Bacteria reproduce with enormous rapidity by fission, but some few are known to produce special reproductive bodies which have the property of resisting the injurious effects of desiccation and heat.

In one sense of the word 'spore,' every segment into which a previously unbroken plastid or cell of a Bacterium divides is a spore. A more special justification of the use of the term is found when occasionally one of the products of division is larger or more refracting than its fellows. Such 'spores' are recognised in the cultivations of Bacterium (*Bacillus tuberculosis*). None of these are sufficiently specialised as reproductive particles to justify thoroughly the use of the term 'spore' in regard to them. In certain species, however, e.g. *Bacterium subtilis*, *Bacterium anthracis*, and *B. megaterium*—the formation of well-defined endospores is characteristic. The protoplasm within each member of a linear aggregate of bacillus-forms separates centrally from itself an ovoid mass (fig. o), on the surface of which a coat of dense mycoprotein is produced. The bacilli themselves die away and decompose, but the ovoid spores remain, and have the power when dried of resisting an exposure to boiling water for as much as fifteen minutes. This property in the spores of *B. subtilis*, which are common in old hay, has led to erroneous inferences as to the 'spontaneous generation,' or 'abiogenesis,' of Bacteria. It is possible, as suggested by De Bary [5], that the Bacteria which produce endospores are widely separate (as to their origin from green algae from the other Bacteria which have no special

seed spores. He divides the Bacteria into Endosporea and Arthrosporea.

Classification and nomenclature of Bacteria. For the present De Bary's division of the Bacteria into Endosporea and Arthrosporea may be accepted. The various generic names in use, such as *Streptococcus*, *Ascococcus*, *Cladotrix*, *Beggiatoa*, *Myconostoc*, *Leuconostoc*, have no logical basis, and produce a good deal of confusion by a false appearance of order. It is probably sufficient at present to limit generic distinctions to the three terms *Micrococcus*, *Bacterium*, and *Sporobacterium*. The genus *Micrococcus* comprises those Bacteriaceæ which are not at present known to exhibit any form of plastid or cell other than that of minute spheres; the genus *Bacterium* contains only those Bacteriaceæ which are known to exhibit in the course of growth rod-like forms of plastids, as well as in many cases micrococcus-forms and spiral and straight filamentous forms; the genus *Sporobacterium* includes only those forms which produce endospores, the so-called *Bacterium* (*Bacillus*) *anthracis*, *B. subtilis*, and *B. megaterium*. Adhering to this nomenclature, we still make use of the terms *vibrio*, *spirillum*, *bacillus*, *clithridium*, *ascococcus*, *zoogloea*, &c., &c., to describe conditions of growth or varieties of cell-form.

With regard to the use of specific names, it is well that every form or group of forms of Bacteriaceæ which definitely recurs in certain conditions, and seems to be, so far as observation has gone, distinct from other known forms or groups of forms, should receive a name. Seeing that many of these names are probably but of temporary significance, it would be well that they should be as definitely descriptive of some feature of the supposed species as possible. The Bacteriaceæ should be named according to their chief properties, place of occurrence, or character of growth, and not after persons.

The following is a list of some of the chief supposed species of Bacteriaceæ which have been described, with an indication of the mode of occurrence. It is by no means an exhaustive list, and it is quite certain that some of the few supposed species here enumerated will, on further inquiry, be found to be phases of growth of other species.

#### Section A.: Endosporea.

##### Genus *Sporobacterium*.

Species: *S. subtilis*, common in hay; *S. anthracis*, in the blood of cattle, sheep, and man, causes the disease known as splenic fever; *S. megaterium*, observed on boiled cabbage; *S. butyricum*, the butyric ferment, occurs in cheese-making, and has been confused with *S. subtilis*.

#### Section B.: Arthrosporea.

##### Genus *Bacterium*.

Species: *B. termo*, the commonest form in putrefying vegetable infusions, but not yet isolated and characterised; *B. lincola*, a larger form occurring in foul ponds and sewage; *B. rubescens*, the protoplasm is wine-red in colour, the plastids and aggregates are of the most varied forms, occurs in ponds on vegetable refuse; *B. dichotoma*, forming branched aggregates (cladotrix) and straight and spiral filaments, common in river water on dead leaves; *B. Kuhniana*, in wells and drain-pipes (Crenothrix); *B. mesenteroides*, forming masses like

frog-spawn on the beet-root juice of sugar refineries; *B. tuberculosis* (fig. 8), in the diseased growths of men and animals suffering from tubercular consumption or phthisis; *B. leprosa*, in the diseased skin of persons suffering from leprosy; *B. mallei*, in men and horses affected with glanders; *B. typhosum*, in the spleen and intestinal glands in fatal cases of typhoid fever; *B. acidi lactici*, in sour milk, the manufacturer of lactic acid; *B. cyanogenum*, in milk, causing it to turn deep blue; *B. pyocyaneum*, in pus in badly dressed wounds, producing an emerald-green colouring matter; *B. alvei*, causing a disease in bee-larvæ known as foul-brood; *B. ureæ*, in urinals, causing the ammoniacal fermentation of urea; *B. aceti*, the vinegar ferment, causing the conversion of ethylic alcohol into acetic acid, occurs in vinegar factories; *B. prodigiosum*, causing blood-red staining of bread, milk, &c., leading to public alarm, and regarded as a portent; *B. ovatum*, causing the silk-worm disease known as 'pebrino'; *B. cuniculicidum*, causing a specific septicæmia in mice and birds; *B. cholerae gallinarum*, in the blood and in the intestines of fowls suffering from chicken cholera; *B. pneumonia cronose*, in the exudation in croupous pneumonia of man; *B. Kochii*, Koch's comma-bacillus, found in the intestines of persons dead of Asiatic cholera (this is a spirillum form which breaks into comma-shaped segments; it is not proved to have any causal relation to cholera); *B. Finkleri*, similar to the last but larger, occurs in ordinary diarrhoea; *B. buccale* and *B. Lewisii*, spiral and filamentous forms breaking into commas which occur in the healthy human mouth.

##### Genus *Micrococcus*.

Species: *M. pyogenes*, in acute abscesses; *M. erysipalatosus*, the cause of erysipelas in man; *M. variolæ*, in the pustules of small-pox; *M. gonorrhææ*, probably the cause of gonorrhœa; *M. bombycis*, causing the disease in silk-worms known as flaccidezza; *M. ventriculi*, in the human stomach, observed in vomit, the 'sarcina ventriculi' of Goodsir; *M. scarlatinae*, probably the cause of scarlet fever in man, and of a disease of the udder in cows; *M. rabidorum*, the cause of rabies, not satisfactorily isolated as yet; besides a list of twenty or thirty more causing special kinds of pyæmia in such animals as rabbits and mice, or producing well-marked colouring matters in colourless vegetable or animal infusions, green, blue, red, yellow, purple.

For a complete enumeration of the supposed 'species' of Bacteriaceæ which have been described, together with a description of each species and many illustrative figures, the reader is referred to the extremely useful and trustworthy treatise by Dr. Edgar Crookshank, entitled *A Manual of Bacteriology*, published by H. K. Lewis, London, 1887. Dr. Crookshank gives complete references to the original description of every known species and to the subsequent literature.

Chemical relations of the Bacteriaceæ.—The above incomplete list gives some idea of the importance attaching to these minute organisms. It is an importance entirely depending on the variety and peculiarity of the chemical decompositions and reconstructions which they excite in the organic compounds forming either the

living or dead bodies of higher plants and animals. Without Bacteria there would be no such thing as putrefaction, and therefore no circulation of the organic elements from their more stable compounds to the condition of albumens, fats, and sugars, and back again to the stable results of putrescence. The earth's surface would be cumbered with the dead bodies of former generations in which the carbon and nitrogen now serving as the food of plants would be permanently locked up. All the evil smells which are not directly due to the chemist, are, with few exceptions, due to the action of Bacteria. Many valuable commercial products, such as acetic acid, lactic acid, and flavouring compounds such as butyric acid, are obtained through their agency. The pungent fumes of stable refuse are caused by their action on urea. It is almost certain that they too are the agents of nitrification in the soil—one species of Bacterium (or Micrococcus?) converting the ammonia produced by another, into nitrates and nitrites. Some Bacteria produce highly poisonous bodies by their action on the albumens of dead animals and plants; amongst these poisons are the ptomaines, which have recently excited the attention of chemists (6). Other Bacteria make their way into living animals and plants and there produce poisonous decomposition-products from the albuminous constituents of the organism, which are recognised in their effects under such names as splenic fever, scarlet fever, phthisis, rabies, &c. It appears that there are many kinds of Bacteria which are parasitic in and on the bodies of men and of other animals, the results of whose chemical activity is not injurious, whilst other kinds (or possibly the same kinds under changed conditions) produce deadly results. Other kinds again, it now seems certain, are not merely innocuous but actually necessary to the healthy life of the animal they inhabit. The digestion of food in the alimentary canal of man and other animals is largely aided by the Bacteria which are present in the intestine in countless myriads, and it appears that the products of digestion owe their chemical characteristics in no small degree to the Bacteria. In the absence of the normal parasitic Bacteria the products of digestion in the human intestine would, it appears highly probable, be of such a nature as to act poisonously when absorbed into the blood. When to these considerations we add the fact that the Bacteria are ubiquitous, abounding in the dust of the air, in all natural waters, and upon all surfaces whether of animate or inanimate objects which have not been chemically cleansed within a few seconds of their examination, some idea may be formed of the immense importance which belongs to the study of the Bacteria in the immediate future.

**Methods of Study.**—At present the state of knowledge of the chemical relations of the Bacteria is extremely fragmentary. They were originally discovered by Leeuwenhoek (7), the Dutch naturalist, in the fluids of the mouth, and various forms were subsequently seen with the microscope in natural waters, ponds, &c., and described by Ehrenberg (8) and others. It was Theodore Schwann (9), however, who, in 1838, demonstrated by a simple experiment that

the Bacteria cause the putrefaction of organic substances, and that without them there is no putrefaction. Later, Pasteur (10), in opposition to Liebig, extended Schwann's observations and conclusions, and established the doctrine of organised ferments, which has proved of immense practical importance, and is as yet only at the commencement of its history. The foundation of the experimental demonstrations of Schwann and of Pasteur lies in the fact that the living protoplasm of the Bacteria is destroyed—that is to say, undergoes an irrevocable chemical change—when subjected to a temperature below or about that of boiling water. Consequently it is possible, by the action of heat, to destroy the Bacteria present in an experimental vessel and its contents, and to protect the contents from the further accession of Bacteria. By this method, and by this method alone, it has been possible to prepare organic infusions, as well as solid gelatine, albumen, &c., which, whilst capable of supporting the life of Bacteria, are yet free from their presence for the time being. Such substances are said to be 'sterilised.' They can be inoculated at pleasure with Bacteria and the effects of the inoculation studied. In order to procure the Bacteria for inoculation in a state of purity, special methods have been devised. So abundant and varied are the kinds of Bacteria present in nearly all natural organic material, that any rough process of inoculation will introduce many kinds of Bacteria simultaneously into a sterilised medium. To separate the various kinds of Bacteria for the purpose of study of each in its isolated condition, three principal methods are employed. The first applies, as is well known, to but one kind, the *Sporobacterium* (*Bacillus subtilis*). The dry spores of this Bacterium resist the destructive effect of boiling water for as much as fifteen minutes, whilst all other known Bacteria are destroyed by it. Hence we have only to boil old hay in water for a few minutes in order to obtain a pure cultivation of *B. subtilis*. The second method (due to Nägeli (11)) is that of fractional dilution. Given a liquid swarming with a mixture of various Bacteria, of which it is estimated by inspection that one individual in twenty is of the kind it is desired to cultivate. Dilute the liquid to such an extent that one drop of it should contain but a single bacterium. Then it is probable that every twentieth drop will contain a single isolated individual of the desired Bacterium. Fifty tubes of sterilised nutrient material are prepared, and to each a single drop of the diluted Bacterium-holding fluid is introduced. One, or possibly more, of the tubes will thus be inoculated with an isolated example of the desired Bacterium, which will multiply in the sterilised nutrient material and thus yield a pure cultivation, and can be recognised by the microscope. The third method is due to Brefeld, of Berlin. By streaking with a needle point a minute drop of fluid containing various Bacteria, over a surface of solid sterilised gelatine, the various Bacteria will be locally isolated along the course of the streak. They will remain thus separated from one another and commence to multiply *in situ*. With a low power of the microscope and a fine needle samples can be now removed from the various

patches of growth and placed in the pure condition in tubes of sterilised nutrient material for further cultivation and study. Similar isolation is effected by mixing liquid gelatine with a dilute infected liquid; when the gelatine solidifies, the various bacteria are embedded apart from one another, and grow in isolated patches, which can then be removed and separately studied by further cultivation.

**Conditions of life required by Bacteria.—General results. (a).**

1. The first general result of these methods of study has been to determine the ubiquity of a large number of different kinds of Bacteria, and the comparative rarity of others. More will be said below as to the study of the distribution of Bacteria in air and water.

2. The Bacteria are found to differ from one another in their relation to free oxygen; the aerobic (Pasteur) will only multiply in the presence of free oxygen; the anaerobic will not flourish except in the absence of free oxygen, or at any rate are indifferent to its presence. Thus *B. anthracis* is eminently aerobic, whilst the Bacterium of malignant oedema is anaerobic. The hay-bacillus (*B. subtilis*) is aerobic, the butyric bacillus of cheese (very similar to the former in appearance) is anaerobic.

3. The source of nitrogen required by Bacteria for building up their protoplasm is various. Very many can take it in as low a form of combination as ammonia. Others require it in higher combination, and some either require it in the form of albumen or at any rate can take it from albumens. It is from albumens that some of the most remarkable products formed by Bacteria result. There is little doubt that the first steps in this process are comparable to the digestion of albumen by animal cells. It is not ascertained that all and any Bacteria can attack albumens. The exact range of the chemical quality of the nitrogenous food possible to each species of Bacterium has yet to be determined.

4. The carbon required by Bacteria may be taken in as low a form as acetic acid by certain species; others can take it from tartaric acid; others can do with nothing lower than a sugar; others again require glycerin or a similar body, and others apparently require their carbon as well as their nitrogen to be presented in the form of a protein. Thus it results that many Bacteria can be nourished by solutions of ammonium tartrate alone, whilst the limits of complexity of necessary food-compounds has various ranges in other species, all of which require accurate determination by the chemist. Little has as yet been ascertained in this direction, but recently Dr. Roux [12] of the Pasteur Institute, has made an extremely important observation showing the necessity for extended research of the kind. It was found by Koch extremely difficult to cultivate the Bacterium tuberculosis, even upon blood-serum kept at the normal temperature of the body. Roux found that the addition of a minute quantity of glycerin to the serum led to the rapid and abundant growth of the *B. tuberculosis* supplied with that mixture; and further, that an ordinary meat broth which alone cannot serve as pabulum for the *B. tuberculosis*, when mixed with a

minute quantity of glycerin acts as a most efficient nutrient medium for this species. It is highly probable that other such special requirements in regard to the chemical nature of their food, exist in respect of other species of Bacteria, whilst others again are more catholic in their nutrition.

5. Water is necessary for the growth of Bacteria as of all living things. Most Bacteria will flourish in the presence of that small amount of water in proportion to solid matter which suffices to constitute mere dampness or moistness. Bacteria are not killed by partial desiccation, but none resist thorough desiccation. In this respect important variations have been determined in different kinds. The spores of the Endospores have a special power of resisting desiccation.

6. There is an optimum temperature favouring the growth of Bacteria, which ranges in various species from 10° to blood heat. Experiments have been made proving that certain species of Bacteria are killed by extreme cold, whilst all are arrested in growth during exposure to the freezing temperature of water. The most careful observations have been made in regard to the effects of exposure to high temperature. Exposure to a temperature of 100° for five minutes kills all Bacteria except those belonging to the Endospores, the spores of which can resist the effects of this exposure for half-an-hour, and possibly longer. Many Bacteria are killed at lower temperatures (e.g. 80°), but careful experiments are wanting.

7. Experiments as to the effects of diminution and increase of atmospheric pressure upon the life of Bacteria have been made, but without reference to particular species. Diminution of pressure is not known to have any influence, whilst experiments made by the writer show that a pressure of thirty atmospheres does not hinder the development of putrefactive Bacteria appreciably, though modifying the chemical results of their life-processes. Extremely high pressures are stated to be destructive of Bacteria.

8. The influence of light is, according to the experiments of Downes [13], inhibitory to the growth of certain Bacteria, but the species so affected have not been determined. This is in accordance with the absence of protective pigment in most species, and the general fact of their growth within turbid liquids and beneath the surface of solid bodies away from the light.

9. Like the yeast-plant, which creates a poison (alcohol) in the nutrient fluids in which it grows, which after reaching a certain percentage causes the arrest of growth and the subsidence of the yeast-cells—so the Bacteria are limited in their growth by the existence of products of their own formation. These products have not been investigated by chemists. But it appears to be established that putrefactive Bacteria growing in a nutrient medium flourish for a time abundantly, then suddenly cease their growth and sink to the bottom of the vessel in which they have been growing, although the nourishing material is not exhausted. A further and exact investigation of this phenomenon by the chemist in regard to various species of Bacteria must lead to results of the

greatest value in relation to the practice of preventive inoculation for disease.

10. A condition of the life of a given species of Bacterium is found in the presence of other species of Bacteria. Frequently one species of Bacterium is the indispensable friend and associate of a second—preparing by its chemical activity the pabulum on which alone the second can thrive. An association of the kind is seen in what is called the vinegar plant, where *Mycoderma* prepares from starch the alcohol which the Bacterium *aceti* converts into acetic acid. So, too, the Bacterium of ammoniacal fermentation is the antecedent of the Bacterium which converts ammonia into nitrites and nitrates. Equally important is the inhibition and possibly the destruction of one species of Bacterium by another. Very little has been ascertained on this important matter, but it appears that the presence of certain putrefactive Bacteria in a nourishing medium will actually prevent the development and growth of certain pathogenic species of Bacteria, although these are present in small numbers. Apart from the question of possible specific incompatibility of two Bacteria, it appears that the question of quantity (*v. Cheyne* [14]) is important. A species of Bacterium which is at the commencement of an inoculation experiment one hundred times more numerous than a second species, may by its rapid development and numbers prevent altogether the growth of the second species.

11. The question of the conditions of life of the Bacteria involves the very important one of their tolerance of the presence of various chemical substances in the liquids in which they grow, those substances the presence of which is not tolerated by the Bacterium being called 'germicides' or 'antiseptics.' On account of the practical importance of destroying or inhibiting the development of putrefactive and pathogenic Bacteria, a good deal of attention has been given to this subject by chemists, but unfortunately it is only recently in the laboratory of Koch [15] that experiments to determine the germicidal action of chemical substances have been made with the necessary discrimination of the species of Bacteria which were the subject of experiment. The fact is now definitely established that some species of Bacteria are killed by chemical substances which do not injuriously affect others, and that the amount of such substances which is effective varies in the case of different species. The inquiry has only as yet been commenced, but it is of immense practical importance, since it may be possible to discover 'germicides' of a generally innocuous character which are specific poisons for certain disease-producing Bacteria, whilst harmless to other Bacteria and harmless to the higher animals in whose tissues the pathogenic Bacteria flourish. Thus weak solutions of quinine sulphate are poisonous to the Bacterium *ureæ*, whilst not injurious to putrefactive Bacteria. Such a solution can be injected into the human bladder without causing irritation, and thus the inflammation resulting from the ammoniacal decomposition of the urine in the bladder by Bacterium *ureæ*, which sometimes gains access thereto, can be entirely arrested. In this inquiry the difference between actual destruc-

tion of the life of the Bacteria, and their arrest or inhibition of growth due to the presence of the antiseptic chemical, have to be distinguished. It is also needful to inquire how far such 'antiseptics,' without killing or inhibiting Bacteria, may modify the physiological processes and chemical results brought about by the latter. The most powerful and generally effective poison for Bacteria appears to be corrosive sublimate. The presence of as little as 1 in 10,000 of this salt in a nutrient fluid has been found to kill Bacteria present. Phenol is also a general and powerful germicide. Boracic acid also and common salt in large quantities are effective. The nature of their action and their effectiveness in regard to different species of Bacteria have yet to be accurately determined. Antiseptic surgery, the future treatment of zymotic disease, and the preservation of perishable articles of food, depend upon the further discoveries of chemists in regard to this matter. It is not improbable that the most effective and useful germicides will be found in chemical substances which, like quinine, resemble those inhibitory products which are produced by the Bacteria themselves and act as the natural obstacles to their excessive multiplication. The more general question of the tolerance of or necessity for the presence on the one hand of free acid, on the other of free alkali in the nutrient fluids suited to different Bacteria, belongs here. It has been studied in regard to many Bacteria in a rough and ready way. Some Bacteria will not flourish in acid media, others will; but accurate quantitative investigations are still wanting.

The products of the activity of Bacteria.—When a species of Bacteria grows in a nutrient fluid of known chemical composition with access to a definite and limited volume of atmospheric oxygen—under given conditions of temperature, pressure, and illumination—certain chemical interchanges occur in the materials contained in the apparatus. These can be accurately determined in certain instances, and the variation of the quantity of change in relation to time can be stated. Various factors of the process, such as temperature, presence or absence of initial chemical substances, &c., can be varied, and the results stated and compared. In no case has such an experiment as yet been accurately made by a chemist. Nevertheless, we know roughly that, in the supposed experimental apparatus above indicated, there will be after a certain time an increase in the weight of mycoprotein and albumina existing in the form of Bacteria, and a corresponding diminution in the C, H, N, and O of the other material in the apparatus. Not only this, but we find certain new chemical compounds present outside the actual substance of the multiplied Bacteria which result from and accompany the growth and life of the particular species experimented upon. The same general statement is true of any higher organism in relation to its necessary pabulum; but whereas in large multicellular organisms the resulting products of the life of the organism are temporarily or permanently held within the mass of the body, in the minute unicellular Bacteria there is no taking in or envelopment of the materials to be acted upon by the living thing, but the organism gets into its food instead of

the food getting into it; consequently processes comparable to the digestive and even to the more deep-seated metabolic processes of higher organisms take place in the nutrient liquid in which the Bacterium lives, being initiated at the surface of the swarming cells constituting the colonies of these minute plants, and serving their economy equally as well as though they occurred in an alimentary canal or in a series of blood-vessels and tissue-spaces. The chemical changes induced by Bacteria should be studied from the same point of view as that taken by the physiologist in regard to the activities of the various cells of the tissues with their diverse and specific functions. We are not yet in a position to treat the subject from this standpoint but we can distinguish with more or less certainty results traceable to respiration, digestion, assimilation, secretion and excretion; the chemical correlatives of these processes are changes described as de-oxidation, oxidation, specific fermentations, specific syntheses.

The obvious results of the activity of Bacteria (setting aside the probably universal evolution of  $\text{CO}_2$  and consumption of free O, common to the Bacteria and all living protoplasm) though by no means necessarily the most important in regard to their own physiology, are the production in the liquids in which they grow of (1) substances having distinctive smells and flavours; (2) substances having brilliant colours; (3) substances having eminently poisonous properties; to these may be added such remarkable results of oxidation as the manufacture of nitrates in soil, of acetic acid in vinegar factories, and the manifestation of light—the phosphorescence of decaying *Tinidones*, and other organic refuse.

The chemical nature of the substances which are thus produced, the by-products which accompany them, and the nature of the processes by which they are originated, have not yet formed the subject of chemical investigation to any large extent. Such knowledge as we have is due to Pasteur [16], to Fitz [17], and one or two others.

It seems probable that we may distinguish amongst these results those which are due to synthesis, by the Bacterium acting on lower compounds taken into its substance, and those which are due to analysis resulting from the action of ferments and other agents secreted by the Bacteria and acting on surrounding material of a high degree of chemical complexity. Of the nature of these ferments we know nothing; their existence is hypothetical but highly probable. To the first category belong certainly many of the brilliant pigments which the Bacteria produce; in most cases these pigments are soluble and pass out from the protoplasm into the surrounding water. In *Bacterium rubescens* the wine-red pigment is not soluble, and remains where it is manufactured in the cells of the plant. The remarkable smelling substances formed by putrescent Bacteria also belong to this group of built-up products, and it is probable that the poisonous products of some pathogenous Bacteria, though not of all, are thus elaborated. The chief experimental reason which we have for concluding that these bodies are built up by the Bacterium from lower com-

pounds is this, that they are formed when the Bacterium is cultivated in a pure solution of ammonium tartrate (with traces of mineral salts) often called Pasteur's or Cohn's solution. Thus the Bacterium of blue milk can be grown and made to produce its blue colour from ammonium tartrate, the Bacterium of green pus similarly, and many of the chromogenic Micrococci, whilst some of the specially active putrefactive Bacteria manufacture foul-smelling products from the same salt when experimentally nourished with it.

In regard to the second group, that of substances resulting from a breaking down of higher chemical bodies brought into relation with the Bacterium (and that probably by the action of a secreted ferment which may be minute in amount and possibly never separated from the surface of the Bacterium-cell), we have to note first of all that the ferment itself belongs to the previous group. Secondly, that various species of Bacteria have been shown to produce ethyls and other alcohols in this way—from sugar and similar bodies—as does the yeast-plant (*Saccharomyces*). Fitz [17] has shown that a certain Bacterium converts glycerin into ethyl alcohol, whilst another converts it into butyl alcohol. Other Bacteria have been shown to convert sugar into gum or into mannite, producing the so-called 'ropy fermentation' of syrups, wine, and beer. Urea is converted into carbonate of ammonia, hippuric acid into benzoic acid and glycocholic. Albumens are broken down into bodies which have not been determined in many cases, but include the ptomaines, neuridine, and trimethylvinyl-ammonium hydrate. Various Bacteria as well as the specific *B. lactici*, produce small quantities of lactic acid from various substances, such as grape-sugar, milk sugar, and glycerin, whilst possessing other ferment-producing action also. Butyric acid is frequently produced in these processes by other Bacteria as well as by the *B. butyricum* of cheese-factories. Exact knowledge is, however, sadly deficient in these matters, owing to the fact that hitherto chemists have not been careful to ascertain what species of Bacterium is present in the fermentations studied by them. Owing to this we do not yet know whether in different nourishing fluids and under different conditions of access of oxygen and of temperature, the same Bacterium can produce different fermentations. Such knowledge as we have tends to a positive answer to the above question. One of the best researches with a known species of Bacterium is that of Vandevelde [18], on the hay bacillus (*B. subtilis*).

Since it is probable that there is this change of chemical activity under changed conditions, it is also probable that a Bacterium which is harmless under ordinary conditions of growth may, when specially cultivated in albuminous media, acquire the property of living in the animal body as a parasite, and there cause deadly disease by its fermentative action, or by the secretion of poisonous products. Buchner [19], starting from this theoretical consideration, has endeavoured to produce the deadly *B. anthracis* of splenic fever from the hay bacillus (*B. subtilis*), and conversely to restore the parasitic form by cultivation to the primitive state. His experi-

ments, though of extreme interest, are not conclusive.

It is difficult to hazard a guess as to whether the poisonous effects of any given Bacterium proved to be concerned in the production of disease, are due to the secretion of a poison by the Bacterium or to the production of one by its fermentative action upon the constituents of the blood, tissues, or intestinal contents. The chemical theory of the antidotal action of inoculation with various 'vaccine' cultivations, which is that favoured by their chief discoverer and investigator, M. Pasteur, would seem to involve the hypothesis that whilst the effective poison is a secretion of the Bacterium, the antidotal material is a chemical compound resulting from the fermentative action of the Bacterium, quite distinct from the poison. This fermentation-product by its accumulation inhibits the development of the Bacterium as alcohol inhibits the further growth of the yeast plant by the fermentative action of which it has been formed. The phagocyte theory of Metschnikow (20) in relation to preventive inoculation does not involve this distinction (see below).

The oxidising action of Bacteria must be considered merely as a special form of their fermentative action. By the latter they produce intermediate chemical substances which are readily oxidised by the free atmospheric oxygen. It is probably thus that acidification proceeds when *B. aceti* converts ethylic alcohol into vinegar or when organic nitrogenous bodies and ammonia in the soil are converted into nitrites and nitrates. There is no evidence of a specific oxidising action on the part of the Bacterium. The phosphorescent substance produced in stale fish, old bones, meat, &c., under certain conditions by certain Bacteria (as yet not precisely determined) may be regarded as an example of one of these intermediate oxidisable substances. The oxidation in this case is accompanied by the evolution of light.

**Special Study of the Occurrence and Distribution of Bacteria in the Atmosphere and in Potable Waters.**—The ubiquity of Bacteria has been demonstrated by the use of sterilised nutrient fluids. If such a fluid be touched by a glass rod or by the finger or by any surface not chemically cleansed, Bacteria are conveyed into the fluid and multiply there with enormous rapidity. Gelatin has been used as a means of studying the number of Bacteria present in the atmosphere or in a sample of water (v. Percy Frankland's researches (21)). However modified, the process is essentially this: a given volume of air is passed through a liquid so as to arrest all Bacteria previously floating in the air. The liquid is then mixed with gelatin, warmed to liquefy the gelatin, and rapidly cooled as a thin layer on a plate. The Bacteria develop at various separate points in the gelatin, giving rise to spherical growths or nests. These are then counted, and the species present may be discriminated by further cultivation. Where water is the subject of investigation the gelatin is directly mixed with a given volume of the water. The results thus obtained have only a subordinate value from the point of view of the hygienist. The majority of Bacteria are perfectly innocuous, and their presence is not—as has been too readily as-

sumed—an indication of the probable presence of pathogenic Bacteria. No such natural association of pathogenic and innocuous Bacteria in definite proportions has been ascertained, and its assumption is not warranted. It is necessary in all cases, if the results are to have hygienic value, to distinguish the kinds or species of Bacteria present and to ascertain their properties. Further, it is quite certain that all species of Bacteria will not flourish in gelatin even when mixed with peptone or such bodies. For instance, one of the most important pathogenic Bacteria—that concerned in tubercular consumption—will not do so. A special pulbulum is needed for this Bacterium, and its presence would not be indicated by the ordinary gelatin cultivation of the contents of a given volume of air. Hence it seems necessary that in addition to careful discrimination of the Bacteria obtained by such experiments on atmospheric and aquatic distribution, there should be a systematic use of various cultivating media for the purpose of demonstrating the presence of various kinds of Bacteria. No doubt many kinds can be secured by the peptonised gelatin method, but if the results of such studies are to have any qualitative hygienic significance, other cultivating media must be simultaneously made use of. All the work at present done on this subject requires doing afresh from this point of view.

**Special Study of Pathogenic Bacteria.**—A large number of most important observations have been made of late years by pathologists—especially by Lister, Pasteur, Koch, Klein, and their pupils—demonstrating not only the presence of Bacteria in the blood and tissues of man and other animals when in a state of disease, but also proving in a certain number of cases that the Bacteria are the cause of specific disease. The proof, which is sufficient, and has been furnished in a limited number of instances, consists in—1. The constant presence of a definite form of Bacterium in the diseased animal and in the specially-diseased parts of it. 2. Its successful removal from the diseased animal, and its pure cultivation on media free from all contamination by particles of the diseased animal. 3. The experimental introduction of the cultivated Bacterium into the body of a healthy animal liable to the disease in question but free from it. 4. The subsequent development of the disease in the inoculated animal. This proof has been furnished in regard to the connection of *B. anthracis* with splenic fever in cattle and sheep, and malignant pustule in man; in regard to *B. tuberculosis* and consumption or phthisis in man and animals; in regard to *B. cholerae* *gallinae* and the cholera of fowls; in regard to *Micrococcus erysipellatus* and erysipelas of man; in regard to certain Bacteria and septicæmic and pyæmic conditions in rats, mice, rabbits, and birds; and in regard to some other diseases of animals. Such a connection is strongly suspected, but not yet proved in the complete manner formulated above in regard to certain observed Bacteria or Micrococci, and the following diseases, viz. small-pox, scarlatina, diphtheria, typhoid fever, cholera asiatica, malaria, yellow-fever, gonorrhœa, &c. The first definite researches in this direction, which were immediately accompanied by practical results of enor-

mous value, were those of Sir Joseph Lister, who showed that the blood-poisoning so frequent in crowded hospitals after surgical operations was due to the access of Bacteria to the wounds where they multiplied and manufactured poisonous products (sepsine, ptomaines?) which were absorbed into the blood. Lister adopted measures for preventing the access of these Bacteria, chiefly by the use of phenol and great cleanliness in instruments, dressings, &c., and thus established the antiseptic system of surgery.

It is remarkable that the researches which have been made on the relation of Bacteria to disease have been mostly of a purely empirical character. Almost the only investigator who has carried the matter further (and with the most brilliant results) is the French chemist Pasteur. The fact is that the question as to what the Bacteria do after entering an animal body is, like the question of their action on substances external to the body, essentially a chemical one. Following up the observations of Toussaint, Pasteur [22] was led to the discovery that the *Bacterium anthracis* when cultivated in broth could be made to assume a condition in which its virulence was greatly diminished. Nevertheless when introduced into the tissues of a sheep, the cultivated Bacterium multiplied, and as a consequence of its growth rendered the sheep so treated resistant to the attacks of the virulent *Bacterium anthracis* taken from another animal's blood.

It was known that an animal which had survived an attack of the virulent *B. anthracis* was thereby rendered 'immune' to subsequent attacks, just as one attack of small-pox renders its survivor 'immune' to that disease. Pasteur conceived the theory that the Bacterium causing the disease in all such cases produces as a by-product—independent of its 'specific poison'—a chemical substance which inhibits its further growth (as in the case of the alcohol produced by the yeast-plant) and that this substance remaining in the animal body protects it from being the seat of further growth of the pathogenic Bacterium. The modified cultivated variety of *B. anthracis* equally produces this substance, and consequently acts as a protective against the incursions of the virulent form. Similarly cow-pox is to be regarded as the result of the growth of a modified small-pox Micrococcus, and thus the protective effects of inoculation with cow-pox are to be explained. Applying this conception Pasteur has successfully protected fowls against fowl-cholera, and has been led to his greatest triumph, the protection by inoculation against rabies and the successful treatment of persons bitten by rabid dogs.

It is extremely interesting and important to observe that the discoveries which have been made in this subject are due to chemical conceptions. Nevertheless there is much probability in the view put forward by Metschnikow (a distinguished zoologist, now director of the Bacteriological Institute of Odessa) to the effect that protective inoculation does not depend upon the development within the inoculated animal of a germicidal poison, resulting from the growth of the very germ which is killed or inhibited by that poison, but is rather due to the education

of the living tissues, and especially of the white corpuscles of the blood, which, he has proved, attack and feed upon Bacteria which are multiplying in the blood and tissues. This property of the white corpuscles leads Metschnikow to term them 'phagocytes,' and, according to him, preventive inoculation depends for its efficacy on the fact that, having learnt to resist and destroy a weaker modification of a pathogenic Bacterium, they are able to deal subsequently with the more virulent variety; whilst it has been suggested that in the struggle between the phagocytes and the inoculated modified Bacteria, there must be a survival of the fittest and a consequent strengthening of the later generations of phagocytes in the protected animal.

However this may be, it is obvious that both the direct study of the chemical history of pathogenic Bacteria and the indirect suggestions derived from further knowledge of the chemical history of Bacteria of all kinds, are of an importance to human life and health which cannot be over-estimated.

In connection with the study of the pathogenic Bacteria which attack man, it is necessary to insist that at present no one has attempted to determine the various kinds of Bacteria which are normally present on the surface of the human body, in the mouth, stomach, and intestines. There appear to be twelve or more present in the healthy human mouth (v. Vignal, [23]). So strangely has this matter been neglected that Koch of Berlin was ignorant, when he discovered the so-called 'comma-bacillus' in the intestines of choleraic subjects in India, that an identical form occurs in the healthy human mouth, as shown by Lewis [24].

**Spontaneous generation or abiogenesis.**—Twenty years ago experiments and observations were brought forward by various more or less competent observers [25] which were interpreted as proving the sudden formation of Bacteria as living things in fluids containing the elements of protoplasm where no germ or living thing previously existed. It is sufficient to say here that these views had a valuable effect in stimulating the investigation of the life-conditions and activities of the Bacteria, but have been definitely proved to be erroneous and to have arisen from the imperfect state of knowledge as to the ubiquity of Bacteria and the power to resist the destructive effect of boiling water possessed by the spores of *Bacterium subtilis*—the hay bacillus.

**Conclusion.**—An endless field of investigation is open in connection with the Bacteria. It seems certain that in the near future we shall be able to control the disease-producing forms, whilst the suggestion presses itself that it may be possible to cultivate and intensify the activities of those which act as scavengers and even to lead some by appropriate methods to the acquirement of new powers, or to the development of activities at present scarcely recognised. There is no reason, from the point of view of the biologist, why these lowest plants should not be cultivated and specialised as breeds and varieties for the service of mankind, as the peach and the strawberry, the wheat and the cabbage have been.

**BALANCE** v. ANALYSIS.

**BALATA**. A substance resembling caoutchouc and gutta-percha, obtained from the dried milky juice of the Bully-tree (*Sapota Muellieri*) (Sperling, Z. [2] 5, 480).

**BALSAM**. This term was originally confined to a single substance called Balm of Gilead or Balsam of Judea, but is now employed generally to denote any liquid resin with aromatic odour. They are composed of solid resins mixed with essential oils. Balsams of Peru, Tolu, Liquidambar, and Storax, contain cinnamic acid; Copaiba balsam, Mecca balsam, and turpentine, do not.

**BARBARIC ACID** v. PARABARIC ACID.

**BARBITIS** ( $C_4H_4O_3$ ). Extracted by oil from barwood (*Sophora nitida*); Plates or needles (from ether), insol. water, v. sl. sol. benzene. Its alcoholic solution is turned red by air. Boiling aqueous KOH converts it into baphic acid  $C_4H_4O_3$  (?), baphinitin ( $C_4H_4O_3$ ) and baphinitone,  $C_4H_4O_3$ . The latter gives a tri-bromo-derivative  $C_4H_4Br_3O_3$ .

**BAPTISIA TINCTORIA**. The root of this plant contains a crystalline alkaloid (Greene, *Ph.* 3, 10, 584).

**BARBALOIN** v. ALBIN, p. 140.

**BARBATIC ACID**  $C_4H_4O_3$ . [186°]. Occurs, together with usnic acid, in a lichen, *Usnea barbata* (Stenhouse & Groves, *C. J.* 37, 405; *A.* 203, 302). Needles or plates (from benzene). Decomposed by boiling milk of lime into  $CO_2$  and (p)-orcin.

**BARBITURIC ACID**

*Malonyl-urea*. Formed by heating malonic acid with urea and  $POCl_3$  at  $100^\circ$  (Grimaux, *C. R.* 88, 85; *A. Ch.* [5] 17, 276), or by reducing di-bromo-barbituric acid with sodium amalgam or  $H_2$ . Prepared by heating alloxantin (1 pt.) with  $H_2SO_4$  (3 or 4 pts.) at  $100^\circ$  as long as  $SO_2$  comes off. The product is poured into water.

*Properties*.—Trimeric prisms (containing 2aq) from water. Sl. sol. cold, v. sol. hot, water.

*Reactions*.—1. Boiling aqueous potash forms malonic acid and urea ( $CO_2$  and  $NH_3$ ).—2.  $HNO_3$  forms nitro-barbituric (diluturic) acid.—3.  $KNO_3$  forms nitroso-barbituric (violuric) acid.—4.  $Br_2$  forms di-bromo-barbituric acid.—5. Heated with glycerin it forms di-barbituric acid, urea, and ammonium malonimide.—6. Cyanogen forms a compound  $C_4H_4N_2O_3(CN)_2$  aq, whence potash forms cyanuric malonic acid.

*Salts*.— $NH_4A'$ : needles, v. sl. sol. cold water.— $Na_2A'$  2aq.— $KHA'$ .— $BaHA'$  2aq.— $PhA'$ .— $CuHA'$  3aq.— $AgHA'$ .— $Ag_2A'$ .

*Acetyl derivative*  $C_4H_4AcN_2O_3$ . A by-product in the preparation of barbituric acid from urea, malonic acid, and  $POCl_3$ . Powder, sol. hot water.

*Di-methyl derivatives*.—I. *Malonyl-dimethyl-urea*  $CO \begin{matrix} \diagup NMe.CO \\ \diagdown NMe.CO \end{matrix} > CH_2$ . [123°].

From malonic acid, di-methyl-urea and  $POCl_3$ , or from di-methyl-urea and cyano-acetyl chloride,  $CN.CH_2.CO.Cl$  (Mulder, *B.* 12, 466). Flat needles, v. sol. water. Forms a di-bromo-derivative ( $175^\circ-180^\circ$ ).

II. *Di-methyl malonyl-urea*  $CO \begin{matrix} \diagup NH.CO \\ \diagdown NH.CO \end{matrix} > CMe_2$ . [265°]. From silver barbiturate and  $MeI$  (Conrad & Guthzeit, *B.* 14, 1643) or from di-methyl-malonic acid, urea, and  $POCl_3$  (Thorne, *C. J.* 39, 545). Plates (from water). V. sl. sol. cold water. Boiling KOH forms di-methyl-malonic acid.

*Salt*.— $Ag_2A'$  1/2 aq.

*Ethyl derivatives*  $CO \begin{matrix} \diagup NH.CO \\ \diagdown NH.CO \end{matrix} > CH_2Et$ . [190°]. From ethyl-malonic acid,  $POCl_3$ , and urea. Gives a bromo-derivative.

*Di-ethyl derivative*  $CO \begin{matrix} \diagup NH.CO \\ \diagdown NH.CO \end{matrix} > OEt$ . [182°]. From silver barbiturate and  $EtI$ .

*Benzyl derivative.*  
 $\text{CO} \begin{smallmatrix} \text{NH.CO} \\ \text{NH.CO} \end{smallmatrix} \text{CH.OH.Ph.}$  [206?]. From  
 benzyl-malonic acid,  $\text{POCl}_3$ , and urea.

*Additional References.*—Finck, *A.* 132, 304; Baeyer, *A.* 130, 136; Conrad & Guthzeit, *B.* 14, 1643; 15, 2844.

Di-barbituric acid  $\text{C}_4\text{H}_2\text{N}_4\text{O}_6$ . The ammonium salt is formed by heating barbituric acid with glycerin at  $150^\circ$ . The acid is an insoluble powder; it gives a di-bromo-derivative.

Salts. —  $\text{NH}_4\text{Ba}^{++} \cdot 2\text{Na}_2\text{A}^{--} \cdot 2\text{aq.}$  —  $\text{KHA}^{--} \cdot \text{aq}$  (Baeyer, *A.* 130, 145).

**BARIUM.** Ba. At. w. 136.8. Mol. w. unknown, as V.D. not determined. Very little known of properties; doubtful if approximately pure Ba has yet been obtained. S.G. abt. 3.5-4 (sinks in  $\text{H}_2\text{SO}_4$ ). S.V.S. abt. 36.5. Chief lines in spectrum are 5850, 5538, 4934, 4553, 3140 (Huggins, *T.* 154, 139).

*Occurrence.*—Not as metal; chiefly as sulphate (*heavy spar*), and carbonate (*witherite*); also as silicate in combination with silicates of Sr, K, or Al, and as oxide in combination with oxide of Mn. Ba compounds occur in many mineral waters; in the ashes of certain plants (Eckart, *A.* 100, 294); and in small quantities in sea water (Dieulafoy, *A. Ch.* [5] 15, 540).

*Formation.*—An amalgam of Ba and Hg is prepared in several ways:—(a) by electrolysis of  $\text{BaCl}_2$  mixed with a little very dilute  $\text{HClAq.}$  using an amalgamated Pt wire as negative electrode (Bunsen, *A.* 92, 248); (b) by electrolysis moist  $\text{BaO}$  using Hg and Pt as electrodes (Davy, *T.* 1803, 303); (c) by bringing hot  $\text{BaO}$  or  $\text{BaCl}_2$  into contact with vapour of K, and treating the product with Hg, or by heating  $\text{BaO}$  with Na and treating with Hg (Kerr, *C. N.* 31, 214); (d) by the action of Na amalgam on conc. warm  $\text{BaCl}_2\text{Aq.}$  (Crookes, *C. N.* 6, 194). By heating Ba amalgam in an atmosphere of H, or of hydrocarbon vapours, metallic Ba was supposed to be obtained; but Donath (*B.* 12, 715) asserts that it is impossible to remove all the Hg even at a white heat, and that the residue contains as much as 62 to 77 p.c. Hg.

*Preparation.*—By electrolysis of fused  $\text{BaCl}_2$  mixed with  $\text{NH}_4\text{Cl}$  in a porcelain crucible in an atmosphere of H; the positive electrode consisting of a cylinder of coke, the negative of an iron wire (Matthiessen, *C. J.* 8, 291).

*Properties and Reactions.*—It is very doubtful whether the properties enumerated by different chemists as characteristic of Ba were determined by experiments made on even approximately pure metal. Davy described Ba as silver-white; Bunsen and Matthiessen as a golden yellow, slightly lustrous, somewhat malleable, metal, which melts at a red heat, but cannot be distilled. It is very easily oxidised, decomposes cold  $\text{H}_2\text{O}$  readily, and burns in the oxyhydrogen flame. As no gaseous compounds of Ba have as yet been obtained, and as the spec. heat of the metal has not been determined, the value to be given to its atomic weight, the combining weight or equivalent having been determined, is arrived at chiefly by considering the analogies between the compounds of Ba and those of other allied elements, chiefly Ca, Sr, Mg, Zn, and Cd. These analogies lead to the formulae  $\text{BaX}$  and  $\text{BaY}$ , for the compounds of

Ba, where  $\text{X} = \text{O}, \text{S}, \text{SO}_3, \text{CO}_3$ , &c., and  $\text{Y} = \text{Cl}, \text{NO}_3, \text{ClO}$ , &c.; these compounds belong to one series. The valency of the atom of Ba in gaseous molecules is unknown. That the atomic weight of Ba is represented by a number the most probable value of which is about 136.8, provided the composition of the Ba compounds is expressed by the general formula  $\text{BaX}_n$ , where  $\text{X} =$  a monovalent atom or group of atoms, was established chiefly by analyses of barium chloride conducted by Marignac (*A.* 68, 215; 106, 165) and Dumas (*A. Ch.* [3] 55, 137). Ba reacts as a strongly positive metal; the salts obtained by replacing H of acids by Ba are stable and well marked;  $\text{BaO}$  and  $\text{BaO}_2\text{H}_2$ ,  $\text{BaS}$  and  $\text{BaS}_2\text{H}_2$ , exhibit no acidic characters;  $\text{BaO}_2\text{H}_2$  is distinctly alkaline, its heat of neutralisation is the same as that of soda and potash (*Th.* 1, 332) [ $\text{BaO} \cdot \text{H}^+\text{Aq.} \cdot \text{H}^+\text{SO}^-\text{Aq.}$ ] = 31,150; [ $\text{BaO} \cdot \text{H}^+\text{Aq.} \cdot 2\text{HClAq.}$ ] = 27,640. Ba combines with O and the halogens with production of much heat and formation of very stable compounds:—[ $\text{Ba}_2\text{O}$ ] = abt. 124,900; [ $\text{Ba}_2\text{Cl}_2$ ] = 194,700; [ $\text{Ba}_2\text{Br}_2$ ] = 170,000 (*Th.* 3, 266); these numbers are approximate only; they were determined indirectly, except that for  $\text{BaO}$ , but the Ba used was not free from Hg. Barium is very closely related to Ca and Sr, and less closely to Mg (v. art. ALKALINE EARTHS, METALS OF THE).

Baryta was obtained by Scheele in 1774 from heavy spar; Davy in 1808 decomposed baryta by electrolysis; the metal was obtained approximately pure in 1855 by Bunsen and Matthiessen.

*Combinations.*—Very few compounds of Ba have been formed directly from the metal. It forms alloys with a few metals; that with mercury (v. *supra*, Formation) is a silver-white body which rapidly decomposes water and cannot be separated into Ba and Hg by heat alone. Beketoff (*A.* 110, 375) obtained an alloy with aluminium, as a greyish solid with a tinge of yellow, by heating Al with  $\text{BaO}_2\text{H}_2$  and a little  $\text{BaCl}_2$ ; it decomposed  $\text{H}_2\text{O}$  rapidly, but the water did not acquire an alkaline reaction. Caron described alloys of Ba with lead, bismuth, antimony, &c., obtained by the action of alloys of these metals with Na on molten  $\text{BaCl}_2$  (*A.* 111, 114).

*Detection.*—Many salts of Ba are soluble in water; some are insoluble; aqueous solutions of Ba salts are ppd. by conc.  $\text{HClAq.}$  or conc.  $\text{HNO}_3\text{Aq.}$  Insoluble Ba salts are decomposed by fusion with alkaline carbonates, giving  $\text{BaCO}_3$ , which dissolves in dilute acids. Fusible salts of Ba impart a pale yellowish-green colour to the non-luminous flame; the colour appears blue-green through a green glass. The emission-spectrum of Ba is characteristic; it contains very many lines in the green; about 750 mgn. Ba may be detected by the spectroscope. Dilute sulphuric acid, or a dilute aqueous solution of sulphates, ppt. white  $\text{BaSO}_4$ , insoluble in alkalis and dilute acids; 1 part  $\text{Ba}_2\text{NO}_3$  in 100,000 parts of water gives an immediate pp.; one part in 400,000 gives a cloudiness on standing. By this reaction Ba salts are distinguished from Ca salts, and to some extent from salts of Sr.

*Estimation.*—1. Ba is usually determined as  $\text{BaSO}_4$ , which is ppd. from fairly conc. solutions, containing a little  $\text{HCl}$  or  $\text{HNO}_3$ , by dilute  $\text{H}_2\text{SO}_4\text{Aq.}$  the pp. is collected, well washed,

and strongly heated, before weighing. If salts of Ce are present,  $\text{CeSO}_4$  may be removed from the pp. by long washing with very dilute  $\text{HClAq}$ , or by digesting with  $\text{Na}_2\text{S}_2\text{O}_4\text{Aq}$  (Diehl, *J. pr.* 79, 80) which dissolves  $\text{CeSO}_4$ , but not  $\text{BaSO}_4$ ,  $\text{PbSO}_4$ , if present, may be removed from the pp. by washing with solution of potash, or of ammonium tartrate.—2. In presence of salts of Ca and Sr, Ba is best estimated as  $\text{BaSiF}_6$ , which is ppd. by freshly prepared  $\text{H}_2\text{SiF}_6\text{Aq}$ , followed by alcohol; after standing 12 hours, the pp. is collected, washed with a mixture of equal volumes of alcohol and water, dried at  $100^\circ$ , and weighed (v. also Rose, *P.* 95, 286, 299, 427).

Barium, alloys of, v. BARIUM; *Combinations.*

Barium, antimonates of, v. ANTIMONATES, under ANTIMONY, ACIDS OF.

Barium, arsenates of, v. ARSENATES, under ARSENIC, ACIDS OF.

Barium, arsenites of, v. ARSENITES, under ARSENIC, ACIDS OF.

Barium, bromide of,  $\text{BaBr}_2$ . Mol. w. unknown, as compound has not been gasified. [abt.  $812^\circ$ ] (Carnelley, *C. J.* 33, 280). S.G. 4.23 (Schiff, *A.* 108, 21). H.F. [ $\text{Ba}, \text{Br}$ ] = 169,960; [ $\text{Ba}, \text{Br}, \text{Aq}$ ] = 174,940 (*Th.* 3, 266).

*Formation.*—1. By acting on  $\text{BaO}, \text{H}_2$  or  $\text{BaS}$ , with  $\text{HBrAq}$ .—2. By adding  $\text{BaS}$  to an aqueous solution of  $\text{Br}$ .—3. Along with  $\text{BaBrO}_3$ , by the action of  $\text{Br}$  on  $\text{BaO}, \text{H}_2\text{Aq}$ .

*Preparation.*—Aqueous  $\text{HBr}$  is neutralised by pure  $\text{BaCO}_3$ , the liquid is boiled down and allowed to crystallise, and the crystals of  $\text{BaBr}_2 \cdot 2\text{H}_2\text{O}$  are heated in a stream of dry air to  $100^\circ$ .

*Properties and Reactions.*—Crystallises with  $2\text{H}_2\text{O}$  in white trimetric plates (Rammelsberg, *P.* 55, 237); according to Hauer (*J. pr.* 80, 230) and Werther (*ibid.* 91, 167) the crystals are monclinic; the hydrated salt is perhaps dimorphous. H.F. [ $\text{BaBr}_2 \cdot 2\text{H}_2\text{O}$ ] = 9,110. [ $\text{Ba}, \text{Br}, 2\text{H}_2\text{O}$ ] = 179,070 (*Th.* 3, 266). Heated to  $75^\circ$ ,  $\text{BaBr}_2 \cdot \text{H}_2\text{O}$  remains, and at  $100^\circ$   $\text{BaBr}_2$  is obtained. The hydrate  $\text{BaBr}_2 \cdot 2\text{H}_2\text{O}$  is soluble in water. S. ( $0^\circ$ ) 98; ( $20^\circ$ ) 104; ( $40^\circ$ ) 114; ( $60^\circ$ ) 123; ( $80^\circ$ ) 135; ( $100^\circ$ ) 149. It is also easily soluble in alcohol. S.G. 3.69 (Schiff, *A.* 108, 21).  $\text{BaBr}_2$  is completely decomposed by heating to redness in dry O (Schulze, *J. pr.* [2] 21, 407). When conc. aqueous solutions of  $\text{BaBr}_2$  and  $\text{BaO}$  are mixed so that the salts are present in the ratio  $\text{BaBr}_2:\text{BaO}$ , crystals of  $\text{BaBr}_2 \cdot \text{BaO} \cdot 5\text{H}_2\text{O}$  (=  $\text{BaBrOII} \cdot 2\text{H}_2\text{O}$ ) separate out (Bechmann, *J. pr.* [2] 26, 388 and 474).

Barium bromide, hydrated, v. BARIUM, BROMIDE OF; *Preparation.*

Barium, chloride of,  $\text{BaCl}_2$ . Mol. w. unknown, as compound has not been gasified. [abt.  $860^\circ$ ] (Carnelley). S.G. 3.75-3.83 (Schroder, *P.* 107, 113). S.H. ( $16^\circ$ - $47^\circ$ ) 0902 (Kopp, *T.* 155, 71); ( $14^\circ$ - $98^\circ$ ) 0896 (Regnault, *A. Ch.* [3] 1, 129). S. ( $5^\circ$ ) 32.2; ( $30^\circ$ ) 38.2; ( $50^\circ$ ) 43.6; ( $80^\circ$ ) 52.4; ( $100^\circ$ ) 58.8 (Mulder; v. Michaelis' *Lehrbuch der Anorgan. Chem.* 3, 670). S. (alcohol 99 p.c.:  $14^\circ$ ) 01; (alcohol at B.P.) 00 (Fresenius, *A.* 59, 127). H.F. [ $\text{Ba}, \text{Cl}$ ] = 194,740; [ $\text{Ba}, \text{Cl}, \text{Aq}$ ] = 196,810 (Thomsen). The following data apply to the hydrate  $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$ : S.G. 3.052 (Schiff, *A.* 108, 21). S.H. ( $18^\circ$ - $46^\circ$ )

171 (Kopp, *T.* 155, 71). S. ( $15^\circ$ ) 45.5; ( $105^\circ$ ) 78. H.F. [ $\text{Ba}, \text{Cl}, 2\text{H}_2\text{O}$ ] = 301,740; [ $\text{Ba}, \text{Cl}, 2\text{H}_2\text{O}$ ] = 7,000 (*Th.* 3, 266). C.E. (sub. abt.  $18^\circ$ - $200^\circ$ ) 0000548 (Playfair & Joule, *C. J.* 1, 131).

*Formation.*—1. By the action of  $\text{Cl}$  on hot  $\text{BaO}$  (Weber, *P.* 112, 619).—2. By passing  $\text{HCl}$  over hot  $\text{BaO}$ ; light is evolved as well as heat; or by adding conc.  $\text{HClAq}$  to  $\text{BaO}$ , boiling down, and drying at  $100^\circ$ .—3. By dissolving  $\text{BaS}$  in conc.  $\text{HClAq}$ , boiling down, and drying at  $100^\circ$ .

*Preparation.*—1. Powdered witherite ( $\text{BaCO}_3$ ) is added little by little to  $\text{HClAq}$ ; the solution is digested in absence of air with more  $\text{BaCO}_3$  (to remove iron, &c.), and is then poured off, evaporated to dryness, and the residue heated to  $100^\circ$  for some time.—2. Two parts of finely powdered heavy spar ( $\text{BaSO}_4$ ) are heated in a crucible to redness with 1 part dry  $\text{CaCl}_2$  and 2 parts iron filings; the fused mass is digested for a short time with 6-8 parts boiling water (by long digestion  $\text{BaSO}_4$  and  $\text{CaCl}_2$  are reformed), the liquid is filtered from  $\text{FeS}$ ,  $\text{CaS}$ , and undecomposed  $\text{BaSO}_4$ , made slightly acid by  $\text{HClAq}$ , and evaporated to dryness at  $100^\circ$ .—3. The solution of  $\text{MnCl}_2$ , which is obtained in making  $\text{Cl}$  from  $\text{MnO}_2$ , is neutralised by  $\text{BaCO}_3$  or  $\text{CaCO}_3$  and evaporated to dryness; the residue is heated with heavy spar and coal; the mass is lixiviated ( $\text{MnS}$ ,  $\text{FeS}$ , and some  $\text{BaSO}_4$  remain), the liquid is treated with a little  $\text{MnCl}_2\text{Aq}$  to decompose any  $\text{BaS}$  present,  $\text{HClAq}$  is added, and the whole is evaporated to dryness (Kuhlmann, *C. R.* 47, 403, 464, 674).

*Properties.*—White salt, easily soluble in water, [ $\text{BaCl}_2\text{Aq}$ ] = 2,070 (*Th.* 3, 266); slightly soluble in alcohol (v. *supra*); solution has a bitter taste and is poisonous. Melts at red heat and cools to an opaque mass.

*Reactions.*—1. Heated in steam,  $\text{HCl}$  is evolved, and residue has an alkaline reaction.—2. Partly oxidised by fusion with potassium chlorate, but unchanged by heating in dry oxygen (Schulze, *J. pr.* [2] 21, 407).—3. Completely decomposed by fusion with silicates.

*Combinations.*—1. Conc. solution of  $\text{BaCl}_2$  mixed with conc.  $\text{BaOAq}$  pps. thin transparent plates of  $\text{BaCl}_2 \cdot \text{BaO} \cdot 5\text{H}_2\text{O}$  (=  $\text{BaClOII} \cdot 2\text{H}_2\text{O}$ ) (Bechmann, *J. pr.* [2] 26, 388, 474).—2. Combines with water with production of heat, [ $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$ ] = 7,000, to form the hydrate  $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$ . This hydrate crystallises in white flat trimetric plates, which are not efflorescent; they lose  $2\text{H}_2\text{O}$  at  $100^\circ$ , but take it up again in moist air. A conc. solution is decomposed to  $\text{Ba}_2\text{NO}_3$  and  $\text{NaCl}$  by heating with  $\text{NaNO}_3$ .

Barium chloride, hydrated, v. BARIUM, CHLORIDE OF; *Combinations*, No. 2.

Barium, cyanide of,  $\text{Ba(CN)}_2$ . Obtained by action of  $\text{HCNAq}$  on  $\text{BaO}, \text{H}_2$  (v. CYANIDES).

Barium, fluochloride of,  $\text{BaFCl}$  (v. BARIUM, FLUORIDE OF).

Barium, fluoride of,  $\text{BaF}_2$ . Mol. w. unknown, as compound has not been gasified. [abt.  $908^\circ$ ] (Carnelley, *C. J.* 33, 280). S.G. 4.58 (Bodeker).

*Preparation.*—1. By ppg.  $\text{Ba}_2\text{NO}_3\text{Aq}$  by  $\text{NaFAq}$ .—2. By the action of  $\text{HFAq}$  on  $\text{BaOAq}$ , or on freshly ppd.  $\text{BaCO}_3$ , and evaporating. The former action is attended with the production of much heat; Guntz (*A. Ch.* [6] 3, 5) gives the values [ $\text{BaOAq}, 2\text{HFAq}$ ] = 34,800; and

[ $\text{BaO} \cdot \text{H}_2\text{O} \cdot 2\text{HF}$ ] = 71,400 (solid  $\text{BaF}_2$  is produced by action of gaseous HF on solid  $\text{BaO} \cdot \text{H}_2\text{O}$ ).

**Properties and Reactions.**—White, finely granular, crystals; scarcely soluble in water, but easily in  $\text{HNO}_3$ ,  $\text{HClAq}$ , and  $\text{HFAq}$ . Not decomposed by heat alone.

**Combinations.**—1. With  $\text{BaCl}_2$  to form  $\text{BaF}_2 \cdot \text{BaCl}_2$  (=  $\text{BaFCl}$ ); obtained by adding  $\text{NH}_4\text{F}$  to a solution of  $\text{BaF}_2$  in  $\text{HClAq}$ ; also by fusing 1 part  $\text{NaF}$  with 6-8 parts  $\text{BaCl}_2$ , and digesting with water; also by adding  $\text{KFAq}$  to  $\text{BaCl}_2\text{Aq}$  and evaporating. Forms white granular crystals, more soluble in water than  $\text{BaF}_2$ ; partly decomposed, with loss of  $\text{BaCl}_2$ , by long-continued washing with water.—2. With  $\text{BF}_3$  to form  $\text{BaF}_2 \cdot 2\text{BF}_3 \cdot 2\text{H}_2\text{O}$  (=  $\text{Ba}(\text{HF})_4 \cdot 2\text{H}_2\text{O}$ ); obtained by acting on  $\text{BaCO}_3$  with  $\text{HBF}_4\text{Aq}$  and evaporating; boric acid separates, and afterwards the double salt (v. *BOROFLOUDES* under *Boron, fluorides* or).—3. With  $\text{SiF}_4$  to form  $\text{BaF}_2 \cdot \text{SiF}_4$  (=  $\text{BaSiF}_6$ ); obtained by adding  $\text{H}_2\text{SiF}_6\text{Aq}$  to a solution of a Ba salt. White solid, very slightly soluble in cold water. S. (17°) .03 and only slightly soluble in  $\text{HClAq}$ . S.G. 4.28. Leaves  $\text{BaF}_2$  when heated; heated with  $\text{NH}_4\text{Cl}$  gives residue of  $\text{BaCl}_2$  (Stollha, *J. pr.* 96, 22) (v. *SILICOFLOUDES* under *SILICON, fluorides* or).

**Barium, hydroxide of.**  $\text{BaO} \cdot \text{H}_2\text{O}$  (*Caustic baryta*). Mol. w. unknown, as compound has not been gasified. S.G. 4.495 (Fihol, *A. Ch.* [3] 21, 415). S. (0°) 1.5, (5°) 1.75, (10°) 2.22, (15°) 2.89, (20°) 3.48, (25°) 4.19, (30°) 5.0, (35°) 6.17, (40°) 7.36, (45°) 9.12, (50°) 11.75, (55°) 14.71, (60°) 18.76, (65°) 24.67, (70°) 31.9, (75°) 56.85, (80°) 90.77 (Rosenstiel a. Rühlmann, *J.* 1870, 314). H.F. [ $\text{Ba} \cdot \text{O}$ ,  $\text{H}^+\text{O}$ ] = 146,500, value only approximate. [ $\text{BaO}$ ,  $\text{H}^+\text{O}$ ] = 22,260 (*Th.* 3, 266).

**Formation.**—1. By heating heavy spar with carbon, dissolving  $\text{BaS}$  formed in hot water, filtering, adding  $\text{CuO}$  or  $\text{ZnO}$  to decompose the  $\text{BaS}$ , filtering, evaporating to dryness, and heating to redness (Müller, *J. pr.* 82, 52; Stahlschmidt, *D. P. J.* 182, 30; Nicklès, *W. J.* 1869, 274).—2. By heating Fe with  $\text{Ba}_2\text{NO}_3$  to redness, dissolving in water, filtering, evaporating, and heating the residue.—3. By the action of steam on  $\text{BaCO}_3$  (Lenoir, *W. J.* 1867, 256).

**Preparation.**—1. Water is added little by little to  $\text{BaO}$  (q. v.); the product is heated to dull redness in a silver dish.—2. Aqueous solution of pure  $\text{NaOH}$ , S.G. about 1.1 to 1.15, the quantity of  $\text{NaOH}$  in which is accurately known, is heated to boiling, a quantity of powdered  $\text{Ba}_2\text{NO}_3$  is added equivalent to the  $\text{NaOH}$  used, the liquid is boiled for a little, if solution is not complete water is added, the hot liquid is filtered quickly and allowed to cool in a closed vessel when crystals of  $\text{BaO} \cdot \text{H}_2\text{O} \cdot 8\text{H}_2\text{O}$  are deposited; these crystals are separated, recrystallised from boiling water, and heated gradually to redness in a silver dish (Mohr, *Ar. Ph.* [2] 88, 38).

**Properties and Reactions.**—A white powder, dissolving in water (v. *supra*) to form an alkaline, caustic, liquid; melts at a full red heat and crystallises on cooling; not decomposed by heat alone, but by heating in a stream of air  $\text{BaO}$  and  $\text{H}_2\text{O}$  are produced. Aqueous solution is markedly alkaline, and neutralises acids with

production of same quantity of base as  $\text{KOH}$  and  $\text{NaOH}$  (*Th.* 1, 832). Does not absorb  $\text{Cl}$ , except in presence of  $\text{H}_2\text{O}$ ; action is then probably  $6\text{BaO} \cdot \text{Aq} + 6\text{Cl}_2 = 5\text{BaCl}_2 \cdot \text{Aq} + \text{Ba}(\text{ClO}_3)_2 \cdot \text{Aq}$  (Weisberg, *B.* 12, 846). Is not acted on by  $\text{CO}_2$  (Scheibler, *B.* 19, 1973).

**Combinations.**—With water with production of heat [ $\text{BaO} \cdot \text{H}_2\text{O} \cdot 8\text{H}_2\text{O}$ ] = 27,470 (*Th.* 3, 266) to form crystals of  $\text{BaO} \cdot \text{H}_2\text{O} \cdot 8\text{H}_2\text{O}$  (Beckmann, *J. pr.* [2] 26, 388, and 474; Fihol found  $7\text{H}_2\text{O}$ , Noad and others  $9\text{H}_2\text{O}$ ). (For preparation of these crystals v. *supra*.) These crystals lose  $7\text{H}_2\text{O}$  over  $\text{H}_2\text{SO}_4$  *in vacuo*, or by heating to  $75^\circ$ , and the eighth  $\text{H}_2\text{O}$  at a red heat; they dissolve in about 3 parts boiling water, and 20 parts water at  $15^\circ$ . The solution is attended with disappearance of heat [ $\text{BaO} \cdot \text{H}_2\text{O} \cdot \text{Aq}$ ] = -15,207 (*Th.* 3, 263). Crystals of  $\text{BaO} \cdot \text{H}_2\text{O} \cdot \text{H}_2\text{O}$  melt at  $83^\circ$ - $85^\circ$  (Veley, *C. J.* 49, 371). According to Beckmann (*J. pr.* [2] 26, 388 and 474) pure  $\text{BaO}$  is obtained by heating  $\text{BaO} \cdot \text{H}_2\text{O} \cdot 8\text{H}_2\text{O}$  in a stream of  $\text{O}$ .

**Barium, iodide of.**  $\text{BaI}_2$ . Mol. w. unknown, as compound has not been gasified. S.G. 4.92 (Fihol, *A. Ch.* [3] 21, 416). H.F. [ $\text{BaI}_2 \cdot \text{Aq}$ ] = 144,520 (*Th.* 3, 266).

**Formation and Preparation.**—Similar to methods for  $\text{BaBr}_2$  (q. v.); also by action of gaseous  $\text{HI}$  on  $\text{BaO}$ .

**Properties and Reactions.**—A white, non-deliquescent, solid; easily soluble in water or alcohol; not decomposed by heat in absence of air, in presence of air  $\text{BaO}$  is formed and  $\text{I}$  evolved; wholly decomposed by heating in  $\text{O}$  (Schulze, *J. pr.* [2] 21, 407); aqueous solution absorbs  $\text{CO}_2$  from air.

**Combinations.**—1. With water to form  $\text{BaI}_2 \cdot 7\text{H}_2\text{O}$  (Croft, *J. pr.* 68, 402; Thomsen, *B.* 10, 1343; Werther, *J. pr.* 91, 331, says the crystals are  $\text{BaI}_2 \cdot 21\text{H}_2\text{O}$ ). This hydrate forms needle-shaped crystals which deliquesce, with partial separation of  $\text{I}$ , in moist air, and melt on heating; heated in absence of air  $\text{BaI}_2$  remains, one  $\text{H}_2\text{O}$  is lost at  $100^\circ$ ,  $5\text{H}_2\text{O}$  at  $125^\circ$  and the seventh  $\text{H}_2\text{O}$  at  $150^\circ$ . Thomsen gives these data [ $\text{BaI}_2 \cdot 7\text{H}_2\text{O}$ ] = 151,370; [ $\text{BaI}_2 \cdot 7\text{H}_2\text{O} \cdot \text{Aq}$ ] = -6,850.—2. With *baryta* to form  $\text{BaO} \cdot \text{BaI}_2 \cdot 5\text{H}_2\text{O}$  (=  $\text{BaIOH} \cdot 2\text{H}_2\text{O}$ ) (Beckmann, *J. pr.* [2] 26, 388 and 474); this salt crystallises from a mixture of conc. solutions of its constituents, in the ratio  $\text{BaO}:\text{BaI}_2$ .

**Barium iodide, hydrated, v. BARIUM, IODIDE or, Combinations, No. 1.**

**Barium, oxides of.** Ba forms two oxides,  $\text{BaO}$  and  $\text{BaO}_2$ ; the former is produced by the action of dry air, or  $\text{O}$ , on Ba;  $\text{BaO}$  heated to about  $450^\circ$  combines with  $\text{O}$  and forms  $\text{BaO}_2$ , which is again reduced to  $\text{BaO}$  at a higher temperature, or by reducing the pressure at  $450^\circ$ . Dry  $\text{BaO}$  is stable, but the presence of water brings about slow decomposition to  $\text{BaO} \cdot \text{H}_2\text{O}$ ; Berthelot (*A. Ch.* [5] 14, 438; comp. *C. R.* 85, 880) gives these data [ $\text{BaO}$ ] = -6,050; [ $\text{BaO} \cdot \text{H}_2\text{O}$ ] = -2,760 (giving  $\text{BaO} \cdot \text{H}_2\text{O}$ ).  $\text{BaO}$  is a strongly basic oxide;  $\text{BaO}_2$  evolves  $\text{O}$  (or  $\text{H}_2\text{O}_2$ ) and forms the same salts as  $\text{BaO}$  when acted on by acids.

**I. BARIUM MONOXIDE (Baryta)**  $\text{BaO}$ . Mol. w. unknown as compound has not been gasified. S.G. 4.63 (Playfair a. Joule, *C. S. Mem.* 3, 84); S.G. crystals 5.722 (Brügelmann, *W.* 2, 464;

4, 277; 9-455 (Berthel, *A. Ch.* [5] 21, 433). *E.P.* [BaO] = 124, 240; [BaO.Aq] = 168, 760 (Th. 3, 266; values approximate only, as Ba used was not pure).

Scheele distinguished baryta from lime in 1774; Gahn recognised the presence of this earth in heavy spar; Bergmann called the earth *terra ponderosa*; Kirwan gave the name *baryta*; Davy, in 1808, proved it to be a metallic oxide.

**Formation.**—1. By the action of dry air on Ba.—2. By strongly heating BaCO<sub>3</sub>, best with 1/10th of carbon whereby CO is formed which does not again combine with the BaO.—3. By strongly heating Ba<sub>2</sub>NO<sub>3</sub>; Rammelsberg (*B. T.* 542) says that an oxide with the composition Ba<sub>2</sub>O<sub>3</sub> (= 2BaO.BaO<sub>2</sub>) is thus produced; Brügelmann (*W.* 2, 466; 4, 277) obtained hexagonal crystals of BaO by this method.—3. By strongly heating BaCl<sub>2</sub>, or BaSO<sub>4</sub>, to white heat, in a current of steam.

**Preparation.**—1. By strongly heating Ba(IO<sub>3</sub>)<sub>2</sub> in a porcelain crucible until all I is removed.—2. By heating dry Ba<sub>2</sub>NO<sub>3</sub> in a capacious porcelain vessel (best a retort), gradually raising the temperature when the salt melts, again raising the temperature to full redness when the residue in the vessel re-solidifies; the heating must be continued until all nitrate is decomposed, but no longer, as on long-continued heating CO<sub>2</sub> is absorbed; the portions in contact with the porcelain take up a little SiO<sub>2</sub> and Al<sub>2</sub>O<sub>3</sub>.

**Properties.**—A grey-white powder, very poisonous; melts at white-heat; takes up H<sub>2</sub>O and CO<sub>2</sub> from the air; dissolves in water to form a caustic alkaline solution (v. BARIUM HYDROXIDE OF).

**Reactions.**—1. Reduced by heating with potassium.—2. Decomposed to Ba + O by electrolysis.—3. Heated in chlorine, BaCl<sub>2</sub> and O are formed.—4. Heated with sulphur, BaS and BaSO<sub>4</sub> are produced.—5. Heated in carbon disulphide vapour, the products are BaS along with BaCO<sub>3</sub>.—6. Heated in phosphorus vapour, in presence of H, barium phosphide BaP<sub>2</sub> (q. v.) and Ba<sub>3</sub>P<sub>2</sub>O<sub>6</sub> are formed (Dumas, *A. Ch.* [2] 32, 364).—7. Heated with arsenic vapour barium arsenite (q. v. under ARSENITES) is said to be produced.

**Combinations.**—1. Combines with water to form BaO.H<sub>2</sub>O (q. v.) with production of much heat, and increase of volume: [BaO, H<sub>2</sub>O] = 22, 260; [BaO, 9H<sub>2</sub>O] = 49, 730 (Th. 3, 266).—2. With carbonic anhydride, to form BaCO<sub>3</sub> (dry BaO has no action on CO<sub>2</sub>; Scheibler, *B.* 19, 1973); with sulphuric anhydride to form BaSO<sub>4</sub>; [BaO, CO<sub>2</sub>] = 62, 220; [BaO, SO<sub>3</sub>] = 110, 590 (Th. 3, 266).—3. Heated in air or oxygen to about 450°, forms BaO<sub>2</sub> (q. v.).—4. With methylic or ethylic alcohol, forms BaO<sub>2</sub>.2CH<sub>3</sub>O or BaO<sub>2</sub>.2C<sub>2</sub>H<sub>5</sub>O.

**II. BARIUM DIOXIDE.** BaO<sub>2</sub>. Mol. w. unknown. S.G. 4.96 (Playfair a. Joule, *C. S. Mem.* 3, 81). Discovered by Thenard (*A. Ch.* 8, 308).

**Formation.**—1. BaO, or a mixture of BaO, H<sub>2</sub> and CaO or MgO, is heated in nearly dry air, or O, to dull redness in a glass or porcelain tube.

**Preparation.**—A mixture of 4 parts finely powdered KClO<sub>3</sub> and 1 part BaO is thrown into a glass by little into a porcelain crucible heated

just to redness; the KCl formed is dissolved out by cold water (Liebig a. Wöhler, *P.* 26, 173); the impure hydrated BaO, containing BaO (Berthelot, *A. Ch.* [5] 6, 207, says the residue is nearly BaO.BaO<sub>2</sub>) is rubbed in a mortar with water, and added little by little to very dilute HClAq, but not in quantity sufficient to neutralise the acid; the solution (which contains H<sub>2</sub>O<sub>2</sub>) is filtered, made slightly alkaline by addition of dilute BaOAq, whereby alumina and iron oxide are ppd., the liquid is again filtered through linen, and an excess of BaOAq is added; lustrous plates of BaO<sub>2</sub>.8H<sub>2</sub>O are ppd.: (the filtrate must contain H<sub>2</sub>O<sub>2</sub>, proved by the production of a blue colour in ether when shaken with ether after acidifying and adding dilute K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>Aq); the pp. is washed with cold water, pressed between filter paper, and placed over H<sub>2</sub>SO<sub>4</sub> until all water is removed and BaO<sub>2</sub> remains (Berthelot, *A. Ch.* [2] 6, 207). Or, H<sub>2</sub>O<sub>2</sub>Aq is added to BaOAq, the pp. of BaO<sub>2</sub>.8H<sub>2</sub>O is washed with cold water, pressed between filter paper, and heated in dry air free from CO<sub>2</sub> to 100°-120° (Schöne, *B.* 6, 1172).—2. Pure BaO is heated to low redness in a stream of O (Brodie, *T.* 1850, 775).

**Properties.**—A white powder, resembling MgO; insoluble in, and combines with, water; melts at full red heat with evolution of O.

**Reactions.**—1. Decomposed by heat to BaO and O; at slightly reduced pressures (760 to 730 mm.) decomposition begins at about 450°; at ordinary pressure at a higher temperature than this; if the BaO produced is allowed to cool to 450° in presence of O under reduced pressure BaO<sub>2</sub> is formed (Boussingault, *A. Ch.* [5] 19, 464).—2. Reduced very slowly by cold, quick, by hot, water, forming BaO.H<sub>2</sub>O [BaO, H<sub>2</sub>O] = 2,760 (giving BaO.H<sub>2</sub> + O, Berthelot, *A. Ch.* [5] 14, 433).—3. Conc. sulphuric acid forms BaSO<sub>4</sub>, and evolves O at temperatures above 60°-70°, but O mixed with ozone at lower temperatures (Houzeau, *C. R.* 40, 949).—4. Heated in dry carbonic anhydride, BaCO<sub>3</sub> and O are produced. 5. Heated with carbon monoxide, or sulphurous anhydride, light and heat are produced, and BaCO<sub>3</sub>, or BaSO<sub>4</sub>, is formed (Wöhler, *A.* 78, 125).—6. Acts as a powerful oxidiser towards carbon, phosphorus, &c., &c. (comp. Slater, *J. pr.* 65, 253; and Brodie, *T.* 1862, 837).—7. With dilute acids forms salts of Ba, and H<sub>2</sub>O, or O.

**Combinations.**—1. With water, combines to form BaO<sub>2</sub>.8H<sub>2</sub>O (produced also by action of BaOAq on H<sub>2</sub>O<sub>2</sub>Aq; v. Preparation); prismatic dimetric crystals, which lose 8H<sub>2</sub>O in vacuo, or by heating in absence of CO<sub>2</sub> to 100°-120°. Berthelot gives the formula BaO<sub>2</sub>.10H<sub>2</sub>O to the hydrate (*A. Ch.* [5] 21, 57); he also describes another hydrate with 7H<sub>2</sub>O (l.c. [5] 6, 207); he gives the data [BaO<sub>2</sub>, 10H<sub>2</sub>O] = 9,100 (l.c. [5] 14, 433).—2. With hydrogen peroxide forms very unstable, monoclinic, crystals, BaO<sub>2</sub>.H<sub>2</sub>O<sub>2</sub>, produced by adding excess of H<sub>2</sub>O<sub>2</sub>Aq to BaOAq, or by adding NH<sub>4</sub>Aq to the solution of a Ba salt mixed with H<sub>2</sub>O<sub>2</sub> (Schöne, *A.* 192, 267).

**Barium, oxysulphides of, v. BARIUM SULPHIDES OF; MONOSULPHIDES, Reactions.**

**Barium, phosphide of.** Described as a grey mass, having the composition BaP<sub>2</sub>, produced by passing H charged with P vapour

over hot  $\text{BaO}$ ; decomposed by  $\text{H}_2\text{O}$ , giving  $\text{PH}_3$  and  $\text{BaHPO}_4$  (Dumas, *A. Ch.* 52, 364).

**Barium, salts of.** Salts produced by replacing H of acids by Ba; they form one series belonging to the form  $\text{BaX}$ , where  $\text{X} = \text{Cl}$ , &c.,  $\text{O}$ ,  $\text{SO}_4$ ,  $\text{CO}_3$ , &c. As none of these salts has been gasified we do not know the molecular weight of any of them; the spec. heat of Ba is undetermined; the formulae are, therefore, based on analogies between these salts and those of similar metals which form gasifiable compounds, especially Zn and Cd, and also on analogies between the salts of Ba and Ca, the atomic weight of the latter metal having been settled by the spec. heat method. Barium forms salts with most, if not all, the acids; very few basic salts are known, and those which have been prepared are generally salts of the weaker acids, e.g. boric, tungstic, molybdic, &c. The haloid salts are very stable; the carbonate, nitrate, iodate, chlorate, &c., are decomposed by heat; Ba salts of the oxyacids are reduced by heating with C, H, or  $\text{CS}_2$ . Most Ba salts are isomorphous with the corresponding salts of Ca and Sr; many with the corresponding salts of Pb. A few Ba salts are soluble in water; the greater number are slightly soluble only, or insoluble (v. BORATES, CARBONATES, PHOSPHATES, SULPHATES, &c., &c.).

**Barium, selenide of.**  $\text{BaSe}$ . Mol. w. unknown. White solid, changing in air, obtained by heating  $\text{BaSeO}_4$  in H to dull redness (Fabre, *C. R.* 102, 1469).

**Barium, selenocyanide of.**  $\text{BaSe}_2(\text{CN})_2$  (?). Prepared by Crookes (*J. pr.* 53, 161). Data very meagre.

**Barium, silicofluoride of.**  $\text{BaSiF}_6$ . v. BARIUM FLUORIDE OF, **Combinations**, No. 3.

**Barium, sulphides and hydrosulphide (or sulphhydrate) of.** Three sulphides of Ba are known; a fourth probably exists in solution. The monosulphide  $\text{BaS}$  is obtained by heating BaO in a stream of  $\text{H}_2\text{S}$ ; by heating  $\text{BaS} + 2\text{S}$  to  $360^\circ$ , the trisulphide  $\text{BaS}_3$  is formed; by boiling  $\text{BaSAq}$  with 3S and crystallising,  $\text{BaS}$  may be prepared; and if  $\text{BaSAq}$  is boiled with considerable excess of S the solution reacts as if it contained a pentasulphide  $\text{BaS}_5$ . Only one hydrosulphide or sulphhydrate,  $\text{BaS.H}_2\text{O}$ , is known. The sulphides and the hydrosulphide are fairly stable compounds; they are soluble in, and partly decomposed by, water; they resemble the sulphides of the alkali metals in their reactions.  $\text{BaS.H}_2\text{O}$  reacts with  $\text{As}_2\text{S}_3$  to form barium thioarsenite  $\text{Ba}_2\text{As}_2\text{S}_5$  (q. v.). Sabatier (*A. Ch.* [5] 22, 1) gives the thermal data:  $-(\text{BaO.H.S}) = 22,100$ ;  $(\text{BaS.O}) = 236,500$ ;  $(\text{BaS.Aq}) = 7,000$ .

**I. Monosulphide.**  $\text{BaS}$ .

**Formation.**—1. BaO is heated in a stream of  $\text{H}_2\text{S}$ .—2.  $\text{BaSO}_4$  is reduced by heating in H or coal gas.

**Preparation.**—1. A stream of  $\text{CO}_2$  is passed through  $\text{CS}_2$  and then over red-hot  $\text{BaCO}_3$ ;  $\text{CS}_2$  must be in excess as  $\text{BaS}$  is decomposed by  $\text{CO}_2$ ; the product is freed from higher sulphides by heating in H (Schöne, *P.* 112, 193).—2.  $\text{BaO.H}_2\text{O}$  (prepared by heating  $\text{BaO.H}_2\text{S.H}_2\text{O}$  to  $60^\circ$  in H) is acted on by dry  $\text{H}_2\text{S}$ ; the products are  $\text{BaS}$  and  $\text{H}_2\text{O}$  (Veley, *C. J.*

49, 367).—3. Crude  $\text{BaS}$  (which is the starting-point in the preparation of many Ba compounds) is prepared by mixing 8 parts heavy spar with 2 parts wood charcoal and 1 part rye meal, all in fine powder, making into a stiff paste with water, rolling into small cylinders, drying, packing in a crucible in alternate layers with charcoal, and gradually heating to full redness (Liebig, *A.* 35, 115; v. also Grüneberg, *J. pr.* 60, 168; Buchholz, *Ar. Ph.* 86, 275; Kuczinsky, *D. P. J.* 135, 455).

**Properties.**—A white amorphous solid; soluble in water; exposed to sunlight and then placed in the dark, it gives off light; oxidised in moist air.

**Reactions.**—1. In moist air decomposes to  $\text{BaCO}_3$  and  $\text{BaS}_2\text{O}_3$  with evolution of  $\text{H}_2\text{S}$ .—2. Heated in air is slowly oxidised.—3. Heated in steam,  $\text{BaSO}_4$  is formed and H evolved (Lauth, *C. C.* 1863, 880).—4. Chlorine, bromine, and iodine, decompose  $\text{BaS}$ , forming  $\text{BaX}_2$  ( $\text{X} = \text{Cl}, \text{Br}$ , or  $\text{I}$ ) and S.—5. Dilute acids form Ba salts and evolve  $\text{H}_2\text{S}$ .—6. Water brings about partial decomposition into  $\text{BaS.H}_2\text{O}$ ,  $\text{BaO.H}_2\text{O}$ , polysulphides and oxysulphides of Ba (v. Veley, *C. J.* 49, 369). The action of water on crude  $\text{BaS}$  has been examined in detail by H. Rose (*P.* 55, 415). If hot water is added in quantity just sufficient for solution, the liquid gives a pp. of  $\text{MnS}$ , without evolution of  $\text{H}_2\text{S}$ , on addition of an aqueous solution of a neutral manganous salt; the solution, therefore, contains either  $\text{BaS}$  or hydroxide and hydrosulphide in the ratio  $\text{BaO.H}_2\text{O}:\text{BaS.H}_2\text{O}$ ;

$(2\text{BaO.H}_2\text{O} + \text{BaS.H}_2\text{O} + 2\text{MnCl}_2\text{Aq} = 2\text{MnS} + 2\text{BaCl}_2\text{Aq} + 2\text{H}_2\text{O})$ . If cold water is added to crude  $\text{BaS}$  in an open vessel, in quantity rather less than sufficient for complete solution, and the liquid is evaporated,  $\text{BaO.H}_2\text{O}$  separates out, then various oxysulphides (v. *infra*), then, on evaporating the mother liquor in a retort, crystals of  $\text{BaS.6H}_2\text{O}$  (v. *infra*, **Combinations**) separate, and finally on evaporating to dryness  $\text{BaS.H}_2\text{O}$  remains.

The oxysulphides prepared as above described, or by cooling the solution obtained by acting on crude  $\text{BaS}$  with boiling water in a closed vessel, seem to be three:

$\text{Ba}_2\text{O}_3\text{S}_5.58\text{H}_2\text{O}$  [ $= 4(\text{BaO.H}_2\text{O}.9\text{H}_2\text{O}).3(\text{BaS.6H}_2\text{O})$ ],  
 $\text{Ba}_2\text{O}_3\text{S}_4.10\text{H}_2\text{O}$  [ $= (\text{BaO.H}_2\text{O}.8\text{H}_2\text{O})(\text{BaS.H}_2\text{O})$ ], and  
 $\text{Ba}_2\text{O}_3\text{S}_3.0.28\text{H}_2\text{O}$  [ $= (\text{BaO.H}_2\text{O}.9\text{H}_2\text{O}).3(\text{BaS.6H}_2\text{O})$ ].  
 The compositions of these bodies are, however, far from settled; the compounds are very unstable and are separated by recrystallisation into  $\text{BaO.H}_2\text{O}$  and  $\text{BaS.H}_2\text{O}$ . If successive quantities of cold water, each less than sufficient for complete solution, are shaken with crude  $\text{BaS}$  in a closed vessel for some hours, the first solution contains  $\text{BaS.H}_2\text{O}$  along with a little of the higher sulphides of Ba (the solution gives  $\text{MnS}$  and also  $\text{H}_2\text{S}$  on addition of  $\text{MnCl}_2\text{Aq}$ ); the next solution contains either  $\text{BaS}$  or  $\text{BaO.H}_2\text{O}$  and  $\text{BaS.H}_2\text{O}$  in the ratio  $\text{BaO.H}_2\text{O}:\text{BaS.H}_2\text{O}$  (with  $\text{MnCl}_2$  it gives  $\text{MnS}$  without evolving  $\text{H}_2\text{S}$ ); the following solutions contain  $\text{BaO.H}_2\text{O}$ , as they give more and more  $\text{MnO.H}_2\text{O}$  on addition of  $\text{MnCl}_2\text{Aq}$  and less and less  $\text{MnS}$ .

**Combinations.**—With water  $\text{BaS}$  forms  $\text{BaS.6H}_2\text{O}$ ; prepared as above described, also by evaporating *in vacuo* a solution of  $\text{BaS}$  after addition of a little S (Schöne, *P.* 112, 193); or

by evaporating  $\text{BaS}, \text{Aq}$  (v. u.) **Sesquioxide.**  $\text{Ba}_2\text{S}_3\text{O}_5$  crystallises in white air-sided plates; slightly soluble in cold, easily in hot water; insoluble in alcohol; loses  $6\text{H}_2\text{O}$  between  $100^\circ$  and  $350^\circ$  with partial decomposition.

**II. THIOSULPHIDE.**  $\text{BaS}_2$ . Prepared by heating 2 parts  $\text{BaS}$  with 1 part  $\text{S}$ , and removing excess of  $\text{S}$  by distilling it off at  $360^\circ$  (Schöne, P. 112, 193). Forms a yellowish-green mass, soluble in hot water; heated to redness in absence of air gives  $\text{BaS} + 2\text{S}$ . A solution of  $\text{BaS}_2$  in much boiling water evaporated *in vacuo* deposits (1)  $\text{BaS}_2 \cdot 6\text{H}_2\text{O}$  (v. *supra*), then (2) a mixture of  $\text{BaS}_2 \cdot \text{H}_2\text{O}$  (v. *infra*) and orange dichroic monoclinic prisms of  $8(\text{BaS}_2 \cdot 6\text{H}_2\text{O}) \cdot (\text{BaS}_2 \cdot \text{H}_2\text{O}) \cdot 6\text{H}_2\text{O}$  (Schöne, l.c.).

**III. TETRASULPHIDE.** Known only in combination with  $\text{H}_2\text{O}$  as  $\text{BaS}_4 \cdot \text{H}_2\text{O}$ . By evaporating a solution of  $\text{BaS}$  in hot water *in vacuo*, or by evaporating  $\text{BaSAq}$  with  $3\text{S}$ , trimetric, dichroic, needles separate; yellow by transmitted, red by reflected, light; soluble in water, may be recrystallised from hot water; insoluble in alcohol; at  $300^\circ$  lose  $\text{H}_2\text{O}$  with decomposition into  $\text{H}_2\text{S}$ ,  $\text{S}$ , and  $\text{BaS}_2$  (Schöne, l.c.). A more hydrated salt, probably  $\text{BaS}_4 \cdot 2\text{H}_2\text{O}$ , was obtained by Veley by dissolving  $\text{S}$  in  $\text{BaS}_2 \cdot \text{H}_2\text{Aq}$  (C. J. 49, 378).

**IV. PENTASULPHIDE.**  $\text{BaS}_5$ . Not known in definite form.  $\text{BaSAq}$  or  $\text{BaS}_2 \cdot \text{H}_2\text{Aq}$  boiled with excess of  $\text{S}$ , yields a yellow alkaline solution, from which on cooling  $\text{S}$  and  $\text{BaS}_2$  separate out; the mother liquor contains  $\text{Ba}$  and  $\text{S}$  in ratio  $\text{Ba}:\text{S}_5$ ; on evaporation crystals of  $\text{S}$  separate out, and  $\text{BaS}_2$  remains in solution (Schöne, l.c. confirming older observations of Berzelius).

**V. HYDROSULPHIDE OR SULPHYDRATE.**  $\text{BaS}, \text{H}_2$ . **Formation.**—By action of  $\text{H}_2\text{O}$  on  $\text{BaS}$  (v. MONOSULPHIDE; *Reactions*, No. 6).

**Preparation.**— $\text{BaOAq}$  (saturated at  $100^\circ$ ) is saturated with  $\text{H}_2\text{S}$  at  $60^\circ\text{--}70^\circ$ ; the liquid is decanted in absence of air, and is cooled to about  $10^\circ$ ; the crystals of  $\text{BaS}, \text{H}_2 \cdot 4\text{H}_2\text{O}$  which separate are dried between paper out of contact with air, and then heated in a stream of  $\text{H}_2$  (v. Veley, C. J. 49, 369).

**Properties and Reactions.**—With  $4\text{H}_2\text{O}$  forms white acicular crystals, which effloresce in air, and gradually absorb  $\text{O}$ , forming  $\text{BaS}_2\text{O}_3$  and  $\text{BaSO}_3$ ; these crystals are soluble in water but insoluble in alcohol; aqueous solution evolves  $\text{H}_2\text{S}$  when boiled; heated to redness out of contact with air,  $\text{H}_2\text{S}$  is removed and  $\text{BaS}$  remains (for details, v. Veley, l.c.).  $\text{BaS}, \text{H}_2$  is strongly basic in its reactions; e.g. with  $\text{As}_2\text{S}_3$  it forms  $\text{Ba}$  thio-arsenite.

**Barium thiocyanide of.**  $\text{Ba}(\text{SCN})_2$ . Obtained by decomposing  $\text{NH}_4\text{SCNAq}$  by  $\text{BaOAq}$  (v. SULPHOCYANIDES, under CYANIDES).

**Barium thio-antimonate of.**  $\text{Ba}_3(\text{SbS})_4$ . Obtained by the action of  $\text{BaCl}_2\text{Aq}$  on  $\text{Na}_3\text{SbSAq}$  (compare THIO-ANTIMONATES under ANTIMONY, THIO-ACIDS OF).

**Barium thio-arsenite of.**  $\text{BaAsS}_2$ . Obtained by digesting  $\text{BaS}, \text{H}_2\text{Aq}$  with  $\text{As}_2\text{S}_3$ ; and **Barium thio-arsenates**  $\text{Ba}_3(\text{AsS})_4$  and  $\text{Ba}(\text{AsS})_2$ , obtained by the action of  $\text{H}_2\text{S}$  on  $\text{BaHAsO}_4\text{Aq}$  (v. THIO-ARSENITES and THIO-ARSENATES under ARSENIC, THIO-ACIDS OF).

M. M. P. M.

**BASES.** *Oxide of Barium, v. BARIUM, OXIDES OF.*

**BASE.**—The characteristic reaction of an acid is that the whole, or a portion, of the hydrogen of an acid can be displaced by a metal, with production of a new body, called a salt, composed of the metal and the elements of the acid, excepting the displaced hydrogen (v. ACIDS). If the oxide of a metal reacts with an acid to form a salt, the hydrogen displaced from the acid combines with the oxygen of the oxide to form water; the products of the reaction are a salt and water. The salt is not characterised by the properties either of the acid, the metal, or the metallic oxide; it has been built upon the metal or metallic oxide by combining this with the acid. The name *base* was given by Rouelle in 1744 to those bodies which reacted with acids to form salts. The name has sometimes been applied to metals, as well as to oxides and hydroxides of metals; at other times it has been confined to compounds of metals with  $\text{H}$  and  $\text{O}$ ; at all times the conception underlying the name has been that of a substance which, while chemically very unlike an acid, reacts with acids to form salts. The dual origin of a salt is implied in the statement that for its production there is required the interaction of an acid and a base. A definition of any one of the terms, *acid*, *base*, *salt*, implies a definition of the other two. The chemical reaction characteristic of bases, as the term is now used, is the production of salts by the mutual reaction of a base and an acid; in some cases water is also formed, in other cases the salt is the sole product. Typical reactions are as follows:

A base may then be (i.) a metallic oxide, (ii.) a metallic hydroxide or an allied compound such as  $\text{NEt}_3\text{OH}$ ,  $\text{PMe}_3\text{OH}$ ,  $\text{SEt}_3\text{OH}$ , &c., (iii.) ammonia or a derivative thereof, e.g.  $\text{NH}_4\text{Et}$ ,  $\text{NMe}_3$ , &c. The terms *strong* and *weak* may be applied to bases with meanings similar to those given to the terms when applied to acids; a strong base, in this sense, is one which, when it reacts in aqueous solution with another base and an acid—all being present in equivalent quantities, and all possible products being soluble in water—combines with a large proportion of the acid and leaves only a small proportion for the other base to combine with. The hydroxides  $\text{MOH}$ , where  $\text{M}$  = an alkali metal or  $\text{Li}$ , are strong bases;  $\text{NH}_3$  is a weak base;  $\text{NMe}_3$  and  $\text{NH}_4\text{Me}$  are stronger bases than  $\text{NH}_3$ ;  $\text{NMe}_3\text{OH}$  and  $\text{SEt}_3\text{OH}$  are nearly as strong bases as the alkalis (v. AFFINITY). By the term a *strong base* is sometimes meant a base which reacts with various acids to form very stable salts; e.g. salts which are not changed by water, hot or cold. In this meaning of the term  $\text{BaO}, \text{H}_2$  is a strong base, but  $\text{BiO}, \text{H}_2$  or  $\text{SnO}, \text{H}_2$  is a weak base. The oxides and hydroxides of polyvalent metals appear to be weaker bases than the corresponding compounds of the monovalent metals. The more positive a metal is, the more basic are its oxides and hydroxides. Sometimes a metallic oxide, or hydrated oxide, may react towards strong acids as a base, and towards strong bases as an acidic oxide; thus

$Al_2O_3 \cdot H_2O$  reacts with  $H_2SO_4$  to form  $Al_2O_3 \cdot 3SO_3$  ( $= Al_2(SO_4)_3$ ), but  $Al_2O_3 \cdot H_2O$  reacts with much  $KOH$  to form  $K_2O \cdot Al_2O_3$  ( $= K_2Al_2O_5$ ). In some cases the basic and acidic functions of a compound may be nearly equal; thus amino-acetic acid ( $? CH_3 \cdot NH_2 \cdot COOH$ ) forms salts by its reactions with bases as other acids do, but it also combines with acids, as  $NH_3$ , does, to form salts. The hydroxides of certain metals which in some of their reactions behave as non-metals react as bases towards most acids, but if oxygen is added to these hydroxides compounds are formed which react as bases only towards the stronger acids and at the same time react as acids towards the stronger bases; such compounds are  $SnO \cdot H_2O$  and  $SnO_2 \cdot H_2O$ , respectively. Bases are sometimes divided into *mono-acid*, *di-acid*, *tri-acid*, &c., according as one reacting weight interacts with one, two, three, &c., reacting weights, of a monobasic acid, to form a salt. The poly-acid bases are weaker than the mono-acid bases. As examples of mono-acid bases may be given  $KOH$ ,  $NH_3$ ,  $NH_4Et$ , &c.; of di-acid bases,  $CaO \cdot H_2O$ ,  $BaO \cdot H_2O$ ,  $ZnO \cdot H_2O$ ,  $NH_4C_2H_5$ , &c.; of tri-acid bases,  $FeO \cdot H_2O$ ,  $C_2H_5(NH_2)OH$ , &c.; of tetra-acid bases,  $ZrO \cdot H_2O$ , &c. (comp. Acids and Salts). M. M. P. M.

**BASES, ORGANIC**, v. ALKALOIDS, AMINES, AMIDES, AZINES, PYRIDINE, QUINOLINE, &c.

The nomenclature of bases containing carbon and nitrogen in one ring is as follows:

**BASIC OXIDES.** Oxides which react with acids to produce salts. The greater number of the metallic oxides are basic; oxides of well-marked non-metals are never basic. The correlative term is *acidic oxides* (v. Bases, Acids, Salts). M. M. P. M.

**BASICITY OF ACIDS** v. ACIDS, BASICITY OF. **BASILICUM, OIL OF.** The essential oil obtained by distilling the leaves of *Ocimum basilicum* with water contains  $C_{10}H_{16} \cdot 3H_2O$  which crystallises in prisms (Dumas a. Peligot, A. 14, 75).

**BASSIA LATIFOLIA.** The seeds of this Himalayan plant yield by pressure a buttery

substance, [77-78], containing oleic and stearic (Hardwick, O. J. 3, 331).

**BASSORIN.** The insoluble gum acid, probably meta-arabic acid, or at least a meta-acid allied thereto (v. ARABIN) of gummy bassore, G. Toritonense, or G. Kutera. These gums consist of a part (the meta-acid) that swells up to a jelly when they are treated with water, and of a soluble part, the alkaline or earthy salt of the acid. C. O'S.

**BASTOSE** v. CELLULOSE.

**BASTYLOUS.** A name sometimes applied to the more positive, usually oxygen-containing, radicles, or groups of atoms, which combine with more negative, or *chlorous*, groups to form salts; e.g.  $K_2O \cdot SO_3$ ,  $K_2O \cdot CrO_3$ ,  $CrO_3 \cdot SO_3$ , &c. The name is sometimes also applied to the elements which displace H from acids with formation of salts. The correlative term is *chlorous*. M. M. P. M.

**BDELLIUM.** A gum-resin (Johnston, J. pr. 26, 145).

**BEBERINE**  $C_{11}H_{21}NO$ . *Bebirine*. [180°]. Occurs, together with a resin (sepirin) and an acid (bebiric acid) in the bark of the bebeeru tree of Demerara (Rodie; MacLagan, A. 48, 106; MacLagan a. Tilley, P. M. 27, 186; v. Planta, A. 77, 333). It is an amorphous powder, v. sl. sol. water, v. e. sol. alcohol, v. sol. ether.  $-B'H_2PtCl_4$ : orange amorphous pp. Buxine has been considered to be identical with bebeerine (Waltz, N. J. P. 14, 15).

**BEE'S WAX** v. WAX.

**BEHENIC ACID**  $C_{22}H_{44}O_2$ . *Benic acid*. [76°]. Occurs as glyceride in oil of ben and in the fatty oil of black mustard seed. Needles, resembling stearic acid.  $-NaA'$ .  $-BaA'$ .  $-PhA'$ .  $-EtA'$  [49°] (Voelcker; Strecker, A. 64, 346).

**BEHENOLIC ACID**  $C_{22}H_{42}O_2$ . *Benolic acid*. [57-5°]. Formed by the action of alcoholic potash on di-bromo-behenic acid (Haussknecht, A. 143, 41). White needles (from alcohol); v. sol. alcohol and ether, insol. water. Not reduced by sodium-amalgam, but combines with  $Br_2$ , forming  $C_{22}H_{40}Br_2O_2$  [47°], and with  $Br_2$ , forming  $C_{22}H_{38}Br_4O_2$  [78°].

Salts.  $-MgA'$ , 3aq.  $-AgA'$ .  $-BaA'$ .

**BELLADONNINE.** An alkaloid occurring in the mother-liquor from which sulphate of atropine (q. v.) has been crystallised (Hübschmann, Schweiz. Z. Pharm. 1858, 123; Kraut, A. 148, 236; B. 13, 165; Ladenburg a. Routh, B. 17, 152; Merling, B. 17, 381). Amorphous, v. sl. sol. water, v. sol. alcohol, ether, and chloroform. It is but slightly attacked by boiling baryta-water, but is split up by alkalis into tropic acid and oxy-tropine  $C_8H_{13}NO_2$ . This would indicate that belladonnine is oxy-atropine  $C_{11}H_{17}NO_2$  (L.). According to Merling, belladonnine is  $C_{11}H_{17}NO_2$  and gives tropine, atropic acid, and iso-atropic acid when boiled with baryta-water. Salts:  $B'H_2PtCl_4$ .  $-B'HAuCl$ .

**BEN, OIL OF.** A fatty oil expressed from the fruits of *Moringa nux behen*. It contains glyceryl palmitate, stearate, oleate, and behenate (v. BEHENIC ACID).

**BENIC ACID** v. BEHENIC ACID.

**BENTYLENE**  $C_8H_{16}$  (223°-228°). S.G. 2-911. Formed by the action of alcoholic potash on

*benzylamine*  $C_6H_5CH_2NH_2$  (Frankland & Tompkins, *J.* 37, 569).

**BENZALDOL**  $C_6H_5CH_2NHO$ . [150°]. A neutral crystalline substance obtained by extracting with alcohol the product of the action of  $ZnEt_2$  on phenyl-acetonitrile (Frankland & Tompkins, *C. J.* 37, 569).

**BENZAL** v. BENZYLIDENE.

**BENZALDEHYDE** v. BENZOIC ALDEHYDE.

**BENZALDOXIM**  $C_6H_5CH=N.OH$ . Oxim of benzoic aldehyde. c. 220° with decomposition. Colourless oil, formed by the action of hydroxylamine on benzoic aldehyde (Petracek, *B.* 15, 2735). Formed also by reducing benzamidoxim with sodium-amalgam (Tiemann & Krüger, *B.* 17, 1692). By heating with HCl it is split up into hydroxylamine and benzaldehyde.  $Ac_2O$  converts it into benzonitrile (Laoh, *B.* 17, 1571).

*Sodium salt*  $C_6H_5CH=N(ONa)aq$ : white easily soluble plates, formed by the action of sodium ethylate on benzaldoxim in alcoholic solution; gives characteristic *pps.* with the salts of the heavy metals.

*Hydrochloride*  $C_6H_5CH=N(OH).HCl$ : white glistening scales, rotates on water.

*Methyl ether*  $C_6H_5CH=N(OMe)$ : (191° uncorr.); colourless oil, lighter than water and slightly soluble; formed by the action of methyl iodide and sodium ethylate on benzaldoxim; by HCl it is split up into benzaldehyde and methyl-hydroxylamine.

*Ethyl ether*  $C_6H_5CH=N(OEt)$ : (208° uncorr.); colourless oil, split up by HCl into ethyl-hydroxylamine and benzaldehyde.

*Propyl ether*  $C_6H_5CH=N(OC_2H_5)$ : (225° uncorr.), colourless oil.

*Isobutyl ether*  $C_6H_5CH=N(OC_3H_7)$ : (238° uncorr.), colourless oil.

*Amyl ether*  $C_6H_5CH=N(OC_5H_{11})$ : (161° uncorr.), colourless oil (Petracek, *B.* 16, 823).

**BENZAMIDE**  $C_6H_5NH_2$ . Mol. w. 121. [130°] (Ciamician & Magnaghi, *B.* 18, 1828). S.G. 1.134 (Schröder, *B.* 12, 1612).

*Formation*.—1. From  $BzCl$  and  $NH_3$ .—2. Together with  $NH_4OBz$  by the action of  $Bz_2O$  on  $NH_3$ .—3. From  $EtOBz$  and  $NH_3$ .—4. By boiling hippuric acid with water and  $PbO_2$  or by heating hippuric acid in a current of dry HCl.

*Properties*.—Monoclinic tables; *a:b:c* = 228:1:1.068;  $\beta = 89^\circ 22'$  (Klein, *A.* 166, 184); v. sl. sol. cold water, m. sol. hot water, especially if it contain  $NH_3$ ; v. sol. alcohol and ether.

*Reactions*.—1. It splits up into water and benzonitrile when heated with *dehydrating agents* ( $P_2O_5$ ,  $P_2S_5$ , or  $H_2SO_4$ ) and to some extent when heated alone at 230°.—2. *Boiling aqueous potash* forms  $KOBz$ .—3. *Boiling acids* form benzoic acid.—4.  $BzCl$  or  $Bz_2O$  form benzonitrile and benzoic acid.—5. Reduced in acid solution by *sodium-amalgam* to benzyl alcohol.—6. Boiling *phenol* gives benzoyl-phenol ( $PhOBz$ ) and  $NH_3$ .—7.  $PCl_5$  forms an unstable substance which rapidly splits up into HCl and benzonitrile (Wallach, *A.* 184, 19).—8.  $COCl_2$  gives benzonitrile, cyphenenine, and di-benzoyl-drea (Schmidt, *J. pr.* [2] 5, 35).—9.  $CS_2$  gives benzonitrile,  $CO_2$ , and HCl (Rathke & Schäfer, *A.* 163, 107).—10. With *chloral* it combines forming  $C_6H_5CH_2NO$  [151°] (Wallach, *B.* 5, 251).—11. With *ethyl iodide* it forms  $N_2$ , benzoic ether, and  $H_2O$ .

(Geyer & Müller, *B.* 4, 962).—12. Converted to *bromine* in *alkaline solution* into anilin (Hofmann, *B.* 18, 2787).—13. A solution of benzamide in *bromine* deposits crystals of unstable  $BzNH_2Br$ .

*Combinations*.— $BzNH_2.HCl$ : long prisms formed by saturating a mixture of benzamide and  $HCl$  aq with HCl (Dessaignes, *A. Ch.* [8] 34, 146; Pinner & Klein, *B.* 10, 1897). When exposed to the air it gives off all its  $HCl$ .— $BzNH_2.3HCl$ . [178°] (*B.* v. Meyer, *J. pr.* [3] 30, 122).

*Salts*.— $(BzNH_2).Hg$  [224°]. Formed by boiling benzamide with water and  $HgO$ . Laminar (from alcohol); v. sol. alcohol and ether.— $BzNH_2.HCl$ : slender needles (Church & Crookes, *C. J.* 17, 151).

*Additional References*.—Liebig & Wöhler, *A.* 3, 268; Fehling, *A.* 28, 48; Schwarz, *A.* 75, 195; Laurent, *Revue Scient.* 16, 891; Henry, *Z.* [2] 5, 446; Brauns, *Ar. Ph.* [3] 126, 214; Oppenheim & Czarnomsky, *B.* 6, 1392; Guareschi, *G.* 4, 465; *A.* 171, 141; Kekulé, *B.* 6, 113; Schiff & Tassinari, *B.* 10, 1785; Friedburg, *A.* 158, 26.

*Benz-chloro-amide*  $C_6H_5CO.NHCl$ . Prepared by gradually adding a conc. solution of chloride of lime to a cold conc. solution of benzamide acidified with  $AcOH$ , the product being shaken out by ether as it is formed. Long colourless prisms (from water) (Blender, *B.* 19, 2274).

*Dibenzamide*  $C_{12}H_{10}NO$ , i.e.  $NH_2Bz$ , [148°]. S. 12 at 15°. Formed, together with benzamide, by the action of  $KNH_2$  on  $BzCl$  dissolved in ether (Baumert & Landolt, *A.* 111, 1); and from benzonitrile (10 g.) and fuming  $H_2SO_4$  (7 g.) (Barth & Schöber, *B.* 9, 975; Gumpert, *J. pr.* [2] 30, 47). Trimetric crystals, *a:b:c* = 931:1:1.063. Sl. sol. boiling water, v. sol. alcohol, ether, and benzene.

*Salts*.— $NaNBz_2$  aq: small prisma, sol. ether.— $AgNBz_2$ .

**BENZAMIDINE**  $C_6H_5NH$ , i.e.  $C_6H_5C(NH).NH_2$ , [75°-80°].

*Preparation*.—Benzonitrile is converted by treatment with isobutyl alcohol and HCl into the hydrochloride of  $C_6H_5C(NH).OC_3H_7$ , whence ammonia produces benzamidine (Pinner & Klein, *B.* 10, 1880; 11, 4).

*Properties*.—v. sol. water, sl. sol. ether, v. a. sol. alcohol; deliquescent; very volatile. Decomposed by heat into  $NH_3$  and cyphenenine.

*Salts*.— $B^+HCl^-$ : flat needles.— $B^+H.PtCl_6^-$ .— $AgC_6H_5N$ .

**BENZAMIDO** v. BENZOYL-AMIDO.

**BENZAMIDO-ACETIC ACID** v. HIPPURIC ACID.

**BENZ-AMIDOXIM**  $C_6H_5N_2O$  i.e.  $PhC(NH).NHOH$ . *Benzoyl-oxaminine*. *Benzoyl-amidoxim*. *Benzyloxy-benzylamine*. [80°].

*Formation*.—1. By the action of hydroxylamine on an alcoholic solution of benzonitrile (Tiemann, *B.* 17, 128).—2. By the action of hydroxylamine on the hydrochloride of benzamidine.—3. As a by-product in the action of hydroxylamine hydrochloride upon benzimide-ethyl-ether.—4. By digesting thio-benzamide with an alcoholic solution of hydroxylamine (Tiemann, *B.* 19, 1698). Long flat monosymmetrical prisms *a:b:c* = 2.502:1:1.077. Volatile.

undecomposed. V. sol. alcohol, ether, benzene, and hot water, sl. sol. cold water. It is poisonous. It dissolves both in acids and alkalis.  $\text{FeCl}_3$  gives a red coloration. The ammoniacal solution gives white crystalline pps. with  $\text{BaCl}_2$ ,  $\text{AgNO}_3$ ,  $\text{Pb}(\text{OAc})_2$ , and  $\text{ZnSO}_4$ . The silver pp. on heating in the solution in which it is formed gives a splendid silver mirror.

**Reactions.**—1. Gives the carbamine reaction with chloroform and alcoholic potash.—2. Nitrous acid forms benzamide.—3. Sodium amalgam reduces it to benzaldoxim and  $\text{NH}_3$  (Tiemann & Nageli, *B.* 18, 1086).—4. When quickly heated at  $170^\circ$  it splits up into benzonitrile and  $\text{NH}_3$ .—5. By heating with acetic anhydride it yields benzenyl-azoxim-ethenyl  $\text{C}_6\text{H}_5\text{C}(\text{NO})\text{CH}_2$ .

**Salts.** A'Na: white crystalline solid, decomposed by water. A'K: crystals. A'Ag: unstable white crystalline pp. A'(CuOH): amorphous dark green pp. A'H, HCl: large flat plates or concentric needles. A'H,  $\text{H}_2\text{SO}_4$ : large prisms. (A'H),  $\text{H}_2\text{SO}_4$ : amorphous solid.

**Ethyl ether.** A'Et:  $[67^\circ]$ ; ( $230^\circ$  uncorr.); prisms; v. sol. alcohol, ether, and benzene, sl. sol. water. By HCl and  $\text{NaNO}_2$  it is converted into benzenyl-methoxim chloride  $\text{C}_6\text{H}_5\text{C}(\text{Cl})(\text{NOMe})$ .

**Ethyl ether.** A'Et:  $[67^\circ]$ ; trimetric plates. By dilute  $\text{H}_2\text{SO}_4$  and sodium nitrite it is converted into benzhydroxime-ethyl ether (benzoyl-hydroxylamine ethyl ether)  $\text{C}_6\text{H}_5\text{C}(\text{OH})(\text{NH})\text{OEt}$ . With HCl and  $\text{NaNO}_2$  it yields benzenyl-ethoxim-chloride.

**Benzyl ether.** A'CH<sub>2</sub>:  $[91^\circ]$ ; scales.

**Benzoyl derivative.**

$\text{C}_6\text{H}_5\text{C}(\text{NH})\text{NOBz}$ :  $[140^\circ]$ ; slender white needles; v. sol. alcohol, ether, and aqueous acids, insol. water. On heating it readily splits off  $\text{H}_2\text{O}$ , giving rise to benzenyl-azoxim-benzenyl  $\text{C}_6\text{H}_5\text{C}(\text{N}=\text{O})\text{C}_6\text{H}_5$ .

**Acetyl derivative.**  $\text{C}_6\text{H}_5\text{C}(\text{NH})\text{NOAc}$ .  $[90^\circ]$ ; thin plates or flat prisms, sol. alcohol, sl. sol. ether, v. sl. sol. water. By boiling with water it loses  $\text{H}_2\text{O}$  and is converted into benzenyl-azoxim-ethenyl.

**Butyryl derivative.**

$\text{C}_6\text{H}_5\text{C}(\text{NH})\text{NO}(\text{C}_4\text{H}_9\text{CO})$ .  $[94^\circ]$ ; fine needles.

**Ethylene ether.**  $(\text{Ph}(\text{NH})\text{NO})_2\text{C}_2\text{H}_4$ .  $[156^\circ]$ . White plates. Sol. alcohol, ether, benzene, and ligroin, insol. water. Formed by heating an alcoholic solution of benz-amidoxim (2 mols.) and acetic anhydride (2 mols.) with ethylene bromide (1 mol.).

**Compound with chloral.**  $\text{C}_6\text{H}_5\text{N}_2\text{Cl}_2\text{O}_2$ .  $[135^\circ]$ . Obtained by mixing the constituents. White crystalline powder. V. sol. alcohol and ether, insol. water. By treatment with  $\text{H}_2\text{SO}_4$  or by long boiling with water it is resolved into its components (Falk, *B.* 19, 1485).

**References.**—Pinner, *B.* 17, 184; Tiemann & Krüger, *B.* 17, 1685; 18, 731, 1053; Tiemann, *B.* 19, 1479, 1668; Schulz, *B.* 18, 1080; Falk, *B.* 19, 1484 (v. also AZOXIMS).

**Benz-amidoxim-carbonic ether.**  $\text{C}_6\text{H}_5\text{C}(\text{NH})\text{N}=\text{O}.\text{CO}.\text{Et}$ .  $[127^\circ]$ . Formed by the action of chloroformic ether upon benz-amidoxim (Falk, *B.* 18, 2467). Long glistening needles. V. sol. alcohol, ether and

benzene, less in ligroin. On heating it splits off alcohol, forming benzenyl-azoxim-carbinol  $\text{C}_6\text{H}_5\text{C}(\text{N}=\text{O})\text{C}(\text{OH})$ .

**Carbonyl-di-benz-amidoxim.**  $\text{C}_{12}\text{H}_{10}\text{O}_2\text{N}_4$ , i.e.  $\text{C}_6\text{H}_5\text{C}(\text{NH})\text{N}=\text{O}.\text{CO}.$   $[129^\circ]$ . Formed by the action of carbonyl chloride upon benz-amidoxim dissolved in benzene (Falk, *B.* 18, 2470). White plates. Sol. alcohol and ether, v. sl. sol. benzene, insol. water.

**BENZ-AMIDOXIM-*m*-CARBOXYLIC ACID.**  $\text{C}_7\text{H}_5\text{N}_2\text{O}_4$ , i.e.  $[3:1]$   $\text{C}_6\text{H}_4(\text{CO}_2\text{H})\text{C}(\text{NOH})\text{NH}_2$ .  $[200^\circ]$ . Crystalline solid. Sol. hot water and alcohol, sl. sol. ether, nearly insol. chloroform and benzene.

**Formation.**—1. By saponification of the ethyl ether which is obtained by combination of *m*-cyano-benzoic ether with hydroxylamine.—2. By digesting a mixture of equivalent quantities of *m*-cyano-benzoic acid, hydroxylamine hydrochloride, and sodium carbonate, in dilute alcoholic solution for 12 hours at  $80^\circ$ – $100^\circ$ .

**Reactions.**—The aqueous solution of the ammonium salt gives sparingly pps. with  $\text{CuSO}_4$ ,  $\text{Pb}(\text{OAc})_2$ ,  $\text{AgNO}_3$ , and  $\text{ZnSO}_4$ . Heated with acetic anhydride it is converted into *m*-carboxy-benzenyl-azoxim-ethenyl  $\text{C}_6\text{H}_4(\text{CO}_2\text{H})\text{C}(\text{N}=\text{O})\text{CH}_2$ .

**Ethyl ether A'Et**  $[118^\circ]$ ; needles; v. sol. alcohol, sl. sol. water (Müller, *B.* 19, 1495).

**Benz-amidoxim-*p*-carboxylic acid.**  $[4:1]$   $\text{C}_6\text{H}_4(\text{CO}_2\text{H})\text{C}(\text{NOH})\text{NH}_2$  [above  $330^\circ$ ]. Formed by digesting *p*-cyanobenzoic acid (1 mol.) hydroxylamine hydrochloride (1 mol.), and sodium carbonate (1 mol.) in dilute alcoholic solution for 18 hours. Sol. dilute alcohol, sl. sol. water, nearly insol. absol. alcohol, ether, and benzene. A dilute aqueous solution of the ammonium salt gives pps. with  $\text{CuSO}_4$  and with  $\text{AgNO}_3$ . By boiling with acetic anhydride it is converted into *p*-carboxy-benzenyl-azoxim-ethenyl  $\text{C}_6\text{H}_4(\text{CO}_2\text{H})\text{C}(\text{N}=\text{O})\text{CH}_2$  (Müller, *B.* 19, 1491).

**Ethyl ether A'Et**  $[135^\circ]$ ; obtained by heating the ethyl ether of *p*-cyanobenzoic acid with hydroxylamine in alcoholic solution (Müller, *B.* 18, 2185). Colourless crystals; sol. boiling water.

**BENZAM-MALONIC ACID v. CARBOXY-PHENYL-MALONAMIC ACID.**

**BENZAM-OXALIC ACID v. CARBOXY-PHENYL-OXAMIC ACID.**

**BENZAM-SEBACIC ACID v. CARBOXY-PHENYL-SEBACAMIC ACID.**

**BENZARSEN- v. ARSENIC, ORGANIC DERIVATIVES OF.**

**BENZARSENIC ACID v. ARSENIC, ORGANIC DERIVATIVES OF.**

**BENZ-BROMO-QUINOLINE v. (B.)-BROMO-QUINOLINE.**

**BENZ-CHLORO-AMIDE v. BENZAMIDE.**

**BENZ-CHLORO-QUINOLINE v. (B.)-CHLORO-QUINOLINE.**

## BENZ-GLYCINATE

**Benz-(α)-methyl-glycoeyamine**  
 $\text{NH}_2\text{C}(\text{NH})\text{NMe} \cdot \text{C}_6\text{H}_4\text{CO}_2\text{H}$ . From benzglycoeyamine, conc. KOH, methyl alcohol, and MeI (Griess, B. 8, 324). Narrow laminae (containing  $1\frac{1}{2}\text{aq}$ ), sl. sol. water and alcohol. Decomposed by baryta into urea and methyl-amido-benzoic acid. —  $\text{B}^1\text{HCl}$  aq. —  $\text{B}^2\text{H}_2\text{PtCl}_2$  2aq.

**Benz-(β)-methyl-glycoeyamine**  
 $\text{NHMe} \cdot \text{C}(\text{NH})\text{NHC}_6\text{H}_4\text{CO}_2\text{H}$ . From 'ethoxy-carbimidamido-benzoic acid' and cold conc.  $\text{NMeH}_2$  solution. Laminae, v. sl. sol. cold water. Boiling baryta forms methyl-urea and amido-benzoic acid. —  $\text{B}^1\text{HCl}$  aq. —  $\text{B}^2\text{H}_2\text{PtCl}_2$  2aq.

## BENZCREATININE

**o-Benz-(α)-methyl-glycoeyamidine**  $\text{C}_8\text{H}_8\text{N}_4\text{O}$   
 $\text{HN}=\text{C}(\text{N}(\text{CH}_3)-\text{C}_6\text{H}_5)-\text{NH}-\text{CO}$ . Prepared by the action of MeI on o-benzglycoeyamidine (Griess, B. 13, 978). White needles. Sol. alcohol, sl. sol. ether and hot water. Insol. caustic alkalis. Salts. —  $\text{B}^1\text{HCl}$  aq.: soluble plates. ( $\text{B}^1\text{HCl}$ )  $\text{PtCl}_4$ .

**o-Benz-(β)-methyl-glycoeyamidine**  
 $\text{C}_8\text{H}_8\text{N}_4\text{O}$  i.e.  $\text{HN}=\text{C}(\text{NH}-\text{C}_6\text{H}_5)-\text{N}(\text{CH}_3)-\text{CO}$ .

Prepared by the action of methylamine on 'ethoxy-cyan-amido-benzoyl' ( $\text{C}_8\text{H}_8\text{N}_4\text{O}$ ) (Griess, B. 13, 978). White needles. Sol. caustic alkalis. Weak base.

Salts. —  $\text{B}^1\text{HCl}$ : small tables or prisms, decomposed by water. — ( $\text{B}^1\text{HCl}$ )  $\text{PtCl}_4$ : sparingly soluble yellow plates.

## BENZCYANIDINE v. BENZOYL CYANIDE.

**BENZELINS**. These bodies, which much resemble the phthalides, are hydroxylated aromatic carbinols, such as di-oxy-tri-phenyl carbinol  $\text{C}_6\text{H}_5\text{C}(\text{C}_6\text{H}_4\text{OH})_2(\text{OH})$ . Prepared by heating phenols with benzotrichloride. The compound from resorcin is yellow, those from cresols, pyrocatechin, hydroquinone, orcin, and (β)-naphthol are yellow or yellowish-red, pyrogallol gives a blue, and (α)-naphthol a green dye. On reduction they give the corresponding derivatives of methane (Doebner, B. 13, 610; A. 217, 227).

## BENZENE $\text{C}_6\text{H}_6$ . Mol. w. 78. $[\rho]_4^{20}$ (80-1°)

(R. Schiff, A. 220, 91). S.G.  $\text{H}^2$  8839 (S.);  $\frac{25}{4}$  8799 (Brühl). V.D. 2-74 (calc. 2-70) (S.). S.H. 3834 + 001043t at  $t^\circ$  (R. Schiff, A. 231, 320). H.C.p. (liquid) 776,000 (Berthelot, A. Ch. [5] 23, 193); 779,530 (Stohmann, Rodatz u. Herzberg, J. pr. [2] 33, 258); (gaseous) 799,350 at 18° (Th.); 787,488 (S. R. u. H.). H.F.p. (as vapour) —12,510 (Thomson, Th. 4, 61); H.F.v. —13,670 (Th.). C.E. (14-2 to 80-1) 00136 (S.). S.V. 95-94 (S.); 95-8 (Ramsay, C. J. 37, 463).  $\mu$  1-5134 (B.);  $\mu$  1-5062 at 14° (Negreano, C. R. 104, 423); 1-5050 (Gladstone, C. J. [2] 7, 101).  $\text{R}_\infty$  42-16 (B.); 44-02 (Kanonnikoff, J. pr. [3] 31, 352). Dielectric constant 2-292 at 14° (N.).

**Formation**. —1. By heating benzoic acid with lime (Mitscherlich, A. 9, 39; Peligot, A. 9, 48, 257; 11, 277; 12, 39), or by passing the vapour of benzoic acid over red-hot iron (Darcet, A. Ch. [2] 66, 99). —2. By heating phthalic acid with lime (Marignac, A. 42, 217). —3. By dry distillation of quinic acid (Wöhler, A. 51, 146). —

Vol. I.

4. By passing oil of bergamot over red-hot lime (Ohma, A. 31, 318). —5. Together with naphthalene, styrene, retene, &c., by heating acetylene to a red heat (Berthelot, A. Ch. [4] 9, 463). Benzene is among the products obtained by passing toluene, xylene, α-cumene, or styrene through a red-hot tube. —6. Metallic succinates give on dry distillation a liquid (hydroquinone dihydride?) which yields benzene when distilled with zinc-dust (v. Richter, J. pr. [2] 20, 206). —7. From benzene sulphonic acid by passing steam through its solution in diluted  $\text{H}_2\text{SO}_4$  at 175° (Armstrong u. Miller, C. J. 45, 118). —8. From phenol (70 g.) by distilling with  $\text{P}_2\text{S}_5$ . The yield is small (16 g.):  $80\text{H}_2\text{OH} + \text{P}_2\text{S}_5 = 2(\text{C}_6\text{H}_5)_2\text{PO} + 3\text{H}_2\text{S} + 2\text{C}_6\text{H}_6$  (A. Gauthier, A. 221, 55). —9. The homologues of benzene when treated at their boiling-points with a current of  $\text{HCl}$  gas in presence of  $\text{AlCl}_3$  evolve  $\text{MeCl}$  and yield lower homologues, but at the same time part of the  $\text{MeCl}$  attacks other portions of the hydrocarbon with production of higher homologues. Thus if  $\text{HCl}$  is passed into boiling xylene containing  $\text{AlCl}_3$ , benzene, toluene, pseudocumene, mesitylene, and durene are obtained (Jacobsen, B. 18, 338; Anschutz u. Immendorff, B. 18, 657). —10. Benzene is produced when benzylidene chloride,  $\text{PhCHCl}_2$ , or benzotrichloride,  $\text{PhCCl}_3$ , is heated with soda-lime (Lamprecht, A. 139, 303). —11. From diazobenzene nitrate or sulphate by heating with alcohol or alcoholic KOH.

**Preparation**. —1. Coal tar is distilled and the fraction boiling below 150° is freed from phenols by shaking with  $\text{NaOH}$  aq. and from bases by shaking with  $\text{H}_2\text{SO}_4$ . It is then rectified. It is convenient to keep the still-head at 100°; toluene is then condensed while benzene passes over (Faraday, T. 1825, 440; Hofmann u. Mansfield, C. J. 1, 211). On the large scale the distillation is performed in an iron boiler, to which is attached a tall vertical column divided into compartments; the fire is regulated so that pure benzene passes over, while its homologues condense and run back to the boiler. Benzene is completely freed from its homologues by cooling with ice and salt, when it solidifies and the homologues which remain fluid may be pressed out. It is freed from thiophene by shaking with conc.  $\text{H}_2\text{SO}_4$ . —2. A mixture of benzoic acid (1 pt.) and slaked lime (3 pts.) is distilled from an iron tube: the product is shaken with  $\text{KOH}$  aq., distilled with steam, dried with  $\text{CaCl}_2$  and Na and rectified. Diphenyl and benzophenone are by-products. The benzoic acid used must not be prepared from toluene, otherwise it will contain thiophenic acid, and the benzene will contain thiophene.

**Properties**. —Colourless, mobile, strongly refracting liquid. Volatile with steam. Scarcely soluble in water, v. sol. alcohol, ether, glacial acetic acid, acetone, and chloroform. Crystallises in trimetric pyramids,  $a:b:c = 831:1:779$  (Groth, Z. [2] 6, 553). It dissolves S, P, I, fats, resins, oils, and many alkaloids. It burns with a luminous flame; 1 g. burnt with excess of hydrogen giving out a light equal to 5-8 g. of spermaceti. When burnt with  $\text{CO}$  and  $\text{CH}_4$ , the light equals that of 6-1 g. and 7-8 g. of spermaceti respectively (Frankland u. Thorne, C. J. 33, 93). There are four bands in the

G G

**ultra-violet absorption spectrum of benzene** (Hartley, *C. J.* 86, 162; 47, 694).

**Detection.**—Benzene is converted by fuming  $\text{HNO}_3$  into nitro-benzene; this is washed with water and reduced by tin and  $\text{HCl}$  to aniline; caustic soda is added and the aniline extracted with ether; the ether is evaporated and the aniline dissolved in much water; the aqueous solution gives a violet colour with bleaching-powder. A mixture of  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$  forms di-nitro-benzene, which, after crystallising from dilute alcohol, melts at  $89^\circ$ .

**Detection of Thiophene in Benzene.**—Thiophene, which is usually present in small quantities in commercial benzene, is indicated by the blue colour produced by shaking with conc.  $\text{H}_2\text{SO}_4$  and isatin (V. Meyer, *B.* 16, 1465; Baeyer, *B.* 12, 1309).

**Impurities.**—Crude benzene may contain traces of toluene, xylene, thiophene,  $\text{CS}_2$ , amylene, crotonylene, alcohol, and acetonitrile.

**Reactions.**—1. Benzene when passed through a red-hot tube forms hydrogen, a little acetylene, diphenyl, benzerythrene  $\text{C}_{12}\text{H}_{10}$ , *p*-di-phenyl-benzene, iso-di-phenyl-benzene, and triphenylene (Berthelot, *Bl.* [2] 6, 272, 279; G. Schultz, *A.* 174, 201; H. Schmidt a. G. Schultz, *A.* 203, 118).—2. A mixture of benzene vapour and ethylene passed through a red-hot tube gives diphenyl and small quantities of anthracene, styrene, and phenanthrene (Berthelot, *Bl.* [2] 7, 113, 274; Ferko, *B.* 20, 660).—3. A mixture of equivalents of benzene and toluene dropped at the rate of 80 g. per hour from a tap funnel into the turned-up end of an iron tube kept at low red heat is converted, to the extent of about 10 per cent., into gases, naphthalene, diphenyl, *p*-tolyl-di-phenyl, *o*-*p*-di-tolyl, (v) and (3) diphenylene-methane, phenanthrene, anthracene, *p*-di-phenyl-benzene, a hydrocarbon  $\text{C}_{22}\text{H}_{18}$ , a hydrocarbon [13°] ( $223^\circ$ – $316^\circ$ ) and two liquid hydrocarbons ( $359^\circ$ – $383^\circ$ ) and ( $404^\circ$ – $427^\circ$ ) (Carnelley, *C. J.* 37, 701).—4. Induction sparks passing through liquid benzene produce a gas that contains 42 p.c. acetylene and 57 p.c. hydrogen (Destrom, *Bl.* [2] 42, 267).—5. Aluminium chloride (p. 147) acting upon a mixture of benzene and an alkyl chloride causes  $\text{HCl}$  to escape with the resulting formation of an alkyl-benzene (Friedel a. Crafts, *C. R.* 84, 1392, 1450; 85, 74; *A. Ch.* [6] 1, 449). (a) Thus methyl chloride passed into a mixture of benzene and  $\text{AlCl}_3$  gives toluene, *o*-, *m*-, and *p*-ylene,  $\psi$ -cumene, mesitylene, durene, isodurene, penta-methyl-benzene, and hexa-methyl-benzene (Ador a. Billiet, *B.* 12, 329; Jacobson, *B.* 14, 2624). (b) Chloral is converted by benzene in presence of  $\text{AlCl}_3$  into  $\text{C}_6\text{H}_5\text{CH}_2\text{CH}(\text{OH})\text{Cl}$ , the hydrochloride of  $\alpha$ -di-chloro-phenyl-acetic aldehyde (Combes, *C. R.* 98, 678; *Bl.* [2] 41, 382). (c) Methylene chloride in presence of  $\text{AlCl}_3$  gives di-phenyl-methane, anthracene, and toluene (Friedel a. Crafts, *Bl.* [2] 41, 322). (d) Chloropicrin,  $\text{AlCl}_3$ , and benzene form  $\text{CHPh}$  and  $\text{PhCOH}$  (Elbs, *B.* 16, 1271). (e) Allyl chloride,  $\text{AlCl}_3$ , and benzene give di-phenyl-propane and *n*-propyl-benzene (Wispok a. Zuber, *A.* 218, 374). (f) Vinyl bromide,  $\text{AlCl}_3$ , and benzene give ethyl-benzene, *u*-di-phenyl-ethane, and di-methyl-anthracene dihydride (Angelis a. Anschütz, *B.* 17, 167). Vinyl tribromide,

on heating, forms a mixture of benzene and phenol (Friedel a. Crafts, *C. R.* 88, 884; Senff, *A.* 220, 282). (h) Sulphur mixed with boiling benzene and  $\text{AlCl}_3$  forms phenyl mercaptan, di-phenyl sulphide and diphenyl disulphide ( $\text{C}_6\text{H}_5$ ) $_2\text{S}_2$  (Friedel a. Crafts, *C.* 86, 884). (i) Sulphurous acid,  $\text{AlCl}_3$ , and benzene give di-phenyl-sulphoxide,  $\text{Ph}_2\text{SO}$  (Colby McLoughlin, *B.* 20, 195). (j) Acetylene in presence of  $\text{AlCl}_3$  forms styrene, di-phenyl-ethane and di-tolyls (Varet a. Vienne, *Bl.* [2] 47, 917). 6. Heated with  $\text{AlCl}_3$  (2 pts.) at  $200^\circ$  in seal tubes benzene gives toluene, ethyl-benzene, and diphenyl (Friedel a. Crafts, *C. R.* 100, 692). 7. Phenol is among the products of oxidation of benzene by  $\text{H}_2\text{O}_2$  (Leeds, *Ph.* [3] 11, 1068; cf. Kingzett, *C. N.* 44, 229). Phenol is also formed when benzene is digested for some days at  $40^\circ$  with cuprous chloride and dilute  $\text{HCl}$  atmospheric oxygen attacking benzene and  $\text{CuCl}_2$  simultaneously (Nencki a. Sieber, *J. p.* [2] 26, 25). In the animal body it is oxidised to hydroquinone and pyrocatechin (Nencki a. Giacosa, *H.* 4, 325; cf. Schultzen a. Naunyn, *C. C.* 1867, 705). Oxidation with  $\text{MnO}_2$  and dilute  $\text{H}_2\text{SO}_4$  produces formic, benzoic, and phthalic acids (Carius, *Z.* 4, 505; *A.* 144, 50). The formation of benzoic acid is perhaps preceded by that of diphenyl (Kekulé,  $\text{PbO}_2$  and  $\text{H}_2\text{SO}_4$  give benzoic acid;  $\text{PbO}_2$  and boiling dilute  $\text{HNO}_3$  give only oxalic acid;  $\text{CrO}$  gives only  $\text{CO}$  (Holder, *Am.* 7, 114).—8.  $\text{PCl}_5$  and a red heat forms  $\text{PhPCl}_2$ , diphenyl, and 1 (Michaelis, *A.* 181, 265; Köhler, *B.* 13, 1623).—9.  $\text{S}_2\text{Cl}_2$  at  $250^\circ$  forms chloro-benzene,  $\text{HCl}$ , and  $\text{S}$  (Schmidt, *B.* 11, 1168).—10. Iodic acid and  $\text{H}_2\text{SO}_4$  on heating slowly form iodo-benzene (Peltzer, *A.* 136, 194).—11.  $\text{SO}_2\text{Cl}_2$  at  $150^\circ$  gives chloro-benzene (Dubois, *Z.* [2] 2, 705).—12.  $\text{ClSO}_3\text{H}$  forms  $\text{PhSO}_3\text{Ph}$ ,  $\text{PhSO}_3\text{Cl}$ , and  $\text{PhSO}_3\text{H}$  (Knapp, *Z.* [2] 5, 41).—13.  $\text{HClO}$  forms  $\text{C}_6\text{H}_5(\text{OH})\text{Cl}$ , the trichlor hydrin of phenos (Carius, *A.* 136, 323).—14. Aqueous  $\text{HClO}_4$  forms trichloro-phenomalic acid, chloro-benzene, and dichloro-quinone (Carius, *A.* 142, 123).—15.  $\text{CrO}_2\text{Cl}_2$  acting upon benzene diluted with  $\text{HOAc}$  (1 vol.) gives trichloro-quinone (Carstanjen, *J. pr.* 107, 331). When benzene is heated with  $\text{CrO}_2\text{Cl}_2$ , there is formed a brown pp. of  $\text{C}_6\text{H}_5(\text{CrO}_2\text{Cl})$ , which is converted into quinone by water (Etard, *A. Ch.* [5] 22, 269).—16. Condenses with sulphuric acid and aldehydes,  $\text{XCHO}$  to  $\text{XCHPh}$ . Thus chloral forms  $\text{CCl}_2\text{CHPh}$ ; bromal forms  $\text{CBr}_2\text{CHPh}$ ; chloro-aldehyde forms  $\text{CH}_2\text{ClCHPh}$ ; formic aldehyde forms  $\text{CH}_2\text{Ph}$  (Goldschmidt, *B.* 6, 985; Hepp, *B.* 6, 1439).—17. Benzene is not attacked by  $\text{HI}$  and  $\text{P}$  at  $250^\circ$ , but at  $280^\circ$  it gives hexahydro-benzene (Wreden a. Znatowicz, *A.* 187, 163; cf. Berthelot, *A. Ch.* [3] 15, 150).—18. When chlorine is passed into benzene containing thiophene  $\text{HCl}$  is evolved and the benzene then no longer gives the indophenine reaction (Willgerodt, *J. pr.* [2] 33, 480). Pure benzene is not attacked by chlorine in the cold and in the dark, but at  $80^\circ$  or in sunlight benzene hexachloride is formed. In presence of carriers, i.e. substances capable of combining with chlorine in more than one proportion, chloro-benzenes are produced.—19. Nitric acid forms nitro- and di-nitro-benzenes.

acted by water into benzene and alumina; with Br & gives  $C_6H_5Br$  (Gustavson, B. 11, 2151).— $(C_6H_5)_2AlBr$ .— $(C_6H_5)_3SbCl_2$ : monoclinic tables, formed by warming  $SbCl_3$  with benzene (Watson Smith & Davis, C. J. 41, 411).

**Potassium-benzene**  $C_6H_5K$  mixed with  $C_6H_6$ . Formed by heating benzene with K at  $250^\circ$  (Abeljan, B. 5, 1027; 9, 10). Blue-black crystalline mass, insol. benzene. Takes fire in air. Converted by water into di-phenyl-benzene, hydrogen, and di-phenyl.

**Constitution of Benzene.**—That the molecular formula of benzene is  $C_6H_6$ , and not any multiple or submultiple of this, is settled, not only by its vapour density, but also by the existence of the following series:  $C_6H_5Cl$ ,  $C_6H_4Cl_2$ ,  $C_6H_3Cl_3$ ,  $C_6H_2Cl_4$ ,  $C_6HCl_5$ ,  $C_6Cl_6$ . We may call the six atoms of hydrogen in the molecule of benzene, *a, b, c, d, e, f*. The first question is: are these six atoms of equal value, or could we, by displacing *a* by an element or radicle R, get a product different from that which would be produced by displacing *b* by R?

**PROPOSITION I.**—Four, at least, of the hydrogen atoms are of equal value.

Ordinary phenol contains hydroxyl in place of one hydrogen: call this hydrogen *a*. Bromine and phosphorus convert phenol into  $C_6H_5Br$ . Sodium and carbonic acid convert this bromophenol into sodic benzoate,  $C_6H_4CO_2Na$ . Hence the carboxyl of benzoic acid has taken the place of the hydrogen atom *a*. Now, there exist three oxy-benzoic acids,  $C_6H_4(OH)(CO_2H)$ , and since in these the carboxyl is in position *a*, the three hydroxyls must have displaced three other atoms of hydrogen, say *b, c, and d*. When distilled with lime, these three acids, instead of giving three phenols, the hydroxyl being in places *b, c, d*, give the same phenol which is identical with the original phenol. Hence, the four hydrogen atoms which we have called *a, b, c, and d*, are of equal value (Ladenburg, B. 7, 1681).

**PROPOSITION II.**—To every hydrogen atom in the molecule of benzene there are two pairs of hydrogen atoms similarly related. Benzoic acid,  $C_6H_5(CO_2H)$  gives bromo-benzoic acid, which we may call  $C_6H_4Br(CO_2H)$ . This, when acted upon by nitric acid, produces two isomeric nitro-bromo-benzoic acids. We may call these

But by reduction these lose their bromine, and give rise to amido-benzoic acids:

$C_6H_4(NH_2)(CO_2H)$ ,  $C_6H_4(NH_2)(CO_2H)$ . These are found to be identical, being anthranilic acid. Hence, *b* and *f* are symmetrically related with regard to *a* (Hübner & Petermann, A. 113, 129). Again, ordinary nitro-benzoic acid may be converted into the above bromo-benzoic acid by the diazo-reaction, hence it is  $C_6H_4(NO_2)(CO_2H)$ . On nitration it gives a di-nitro-benzoic acid which we may call  $C_6H_3(NO_2)(NO_2)(CO_2H)$ , which may be reduced to  $C_6H_4(NO_2)(NH_2)(CO_2H)$ ,

where we may alternatively regard  $C_6H_4(NO_2)Cl(CO_2H)$ ,  $C_6H_4(NH_2)Cl(CO_2H)$ , and  $C_6H_4Cl(CO_2H)$ . The last acid is found to be identical with the chloro-benzoic acid

$C_6H_4Cl(CO_2H)$  obtained by the diazo-reaction from  $C_6H_5(NO_2)(CO_2H)$ . Hence *c* and *e* are similarly related with regard to *a*. Therefore we have a second pair of hydrogen atoms similarly related with regard to *a* (Hübner, A. 232, 94, cf. Wroblewsky, A. 192, 206).

**PROPOSITION III.**—The six atoms of hydrogen in the molecule of benzene are of equal value. Since *a, b, c, and d* are of equal value, and the situations of *f* and *e* are similar to those of *b* and *c* respectively, all six atoms of hydrogen are similarly placed and of equal value. This conclusion might also be deduced from the fact that no instance of isomerism among the mono-substitution products of benzene has been proved.

**Isomerism among di-substitution products.** Since two pairs of hydrogen atoms are symmetrical to any fifth, it follows, that only three derivatives of benzene can exist with a given formula. Using our former notation, these are —  $ab = af$ ,  $ac = ar$ , and  $ad$ .

This is confirmed by experiment.

**Structural formula.**—Since the atom of carbon is assumed to be tetravalent, all the hydrogen atoms of benzene cannot be attached to the same atom of carbon, and symmetry requires that they must be either each attached to one carbon, or else three must be attached to one, and three to another; or, finally, two must be attached to one carbon, two to another, and the remaining two to a third. The two latter hypotheses do not account for more than two di-substitution products; hence the former is established. The carbon atoms must be united amongst themselves in a symmetrical fashion. Each atom of carbon must be united with at least two other atoms, or the group would not hold together; but it may be united with three other atoms. The former hypothesis results in the formula:

This is the ring-formula of Kekulé, which is one of the two formulae originally put forward by him (A. 137, 160). If we number the positions occupied by the atoms of hydrogen thus,

we see that the formula shows the possible existence of four di-substitution products—viz. 1:4, 1:3, 1:2 and 1:6. To get over this difficulty, Kekulé resorts to a peculiar mechanical hypothesis. He supposes that what we represent by straight lines in a formula really indicates that two atoms vibrate with reference to each other so that the above formula would mean that, in a given unit of time, 1 approaches 6 twice as often as it approaches 2; and so for the other atoms. Now, if this were the case, the di-substitution product 1:2 would differ from 1:6; but he assumes that the motions of 1 are as follows: first, it approaches 6 twice; then it approaches 2 once; next it approaches 6 once; then it approaches 2 twice; then 6 twice; 2 once; and so on. This is equivalent to saying that the above formula for benzene is true for one instant, after which it changes to

and the next instant it changes back again, and so on. This assumption leads to the deduction that only three di-derivatives can exist, and, if we could devise no other formula for benzene, we should be obliged to accept it. As a matter of fact, it is now almost universally adopted; not so much on its intrinsic merits, as on account of the enormous service which it has rendered to chemistry.

There remains, however, a second hypothesis possible, which is that every atom of carbon is united to three other atoms. The following mechanical construction may help to elucidate this hypothesis.

Let three rods be driven into the ground at the angles of an equilateral triangle, and let the top of each rod be joined by elastic string with the bottom of each of the two adjacent rods. A figure somewhat resembling a coronet is obtained, and we may suppose the six atoms of carbon in the benzene molecule situated at the two extremities of each of the three rods. At first sight it might appear that this representation of the benzene molecule would indicate the existence of three di-derivatives—namely, (1) when the substituted hydrogens are attached to two carbon atoms at opposite ends of one rod; (2) when they are attached to carbon atoms which are both on the upper or both on the lower ends of two different rods; (3) when one carbon atom is on the upper end of one rod and the other is on the lower end of another rod. But if we assume that formulae and other mechanical symbols represent not actual position in space, but merely modes of combination of atoms, especially showing which atoms are directly and which indirectly united, (3) is identical with (1), for it can be converted into (1) by simply holding the string, at the opposite ends of which the carbon atoms have been placed, upright, and doing the same with the two corre-

sponding strings. The rods will now take positions formerly occupied by the strings now held upright, and the figure will be the same as before. Hence this figure for benzene gives only two di-derivations, and accordingly it must be discarded. When the figure we have just considered is projected on a plane it assumes the form:

This figure, by simply twisting the central rod, is converted into

and if the central rod be now elongated we get:

This symbol, which has been a favourite with some chemists, must, of course, be abandoned along with the solid figure from which it is derived; but it is also very easy to see that 1:2 and 1:4 di-derivatives, are identical, since if we pick up the carbon atom (4) and place it upon (2), and then take up (2) and place it where (4) was, supposing all the while that the connections, which we may imagine to be elastic, are not broken, the figure will be wholly unaltered.

There remains one other benzene formula: it is obtained by joining the ends of the three rods placed vertically by six strings as before, but with this difference, that whereas in the previous formula the top of one rod is joined to the bottom of the others, in this formula the top of each rod is joined with the top of each of the others, and the bottom of each rod is joined with the bottom of each of the others. We thus obtain a right-angled prism on a triangular base. This formula, defended by Ladenburg (*Theorie der aromatischen Verbindungen*, Braunschweig, 1876), is capable of explaining most of the reactions of benzene, and the objections that have been brought against it are chiefly that

result of misconception of its nature. Projected upon a plane this formula becomes:

If the upper triangle be rotated through  $180^\circ$ , and then the figure be projected upon a horizontal plane, we obtain a figure which resembles a star:

The two former figures are not symmetrical, but the latter is clearly so, and it has this advantage over the prism formula, that, if the atoms of carbon are numbered consecutively, they correspond to the atoms of carbon in Kekulé's formula, also numbered consecutively; whereas this would not be the case with the second of the three formulae here given, which is that used by Ladenburg.

For most purposes it will not be necessary to decide which formula we adopt, for both the star-formula and the formula of Kekulé:

may be represented by the simple hexagon:

The numbering of the carbon atoms here given is used throughout this dictionary. Thus, the expression  $C_6H_5Br$ , [1:5] must be taken to mean that one bromine atom has displaced the hydrogen atom numbered (1) and the other the hydrogen atom numbered (5).

Physicists have tried to decide between the formula of Kekulé and Ladenburg. Thomson

(*Ph. iv. 373; A. 205, 180*) considers that thermochemical data favour Ladenburg's formula, but the assumptions he makes in the course of his argument lead him in other cases to impossible conclusions. The specific volume of benzene is 99; whereas that calculated on the assumption that the S.V. of  $C=11$ , and that of  $H=5.5$  is 99: this would merely show that the relation between the carbon atoms in the benzene molecule is different from that in saturated paraffins. If we compare the specific volumes of hexane, diallyl, and benzene, we find that:

Hexane,  $C_6H_{14}$ , has a S.V. 140.0

Diallyl,  $C_6H_{10}$ , " " 125.7

Benzene,  $C_6H_6$ , " " 95.9.

We see that the difference between the first and second (14.3) is less than that between the second and third (29.8) and that when hexane is converted into benzene by the removal of 8H the S.V. is lowered by  $8 \times 5.5$ , while the removal of 4H, in converting hexane into diallyl, lowers S.V. by only  $4 \times 5.5$ . That is to say the want of saturation of diallyl is accompanied by an unusually large specific volume, whereas this is not observed in the case of benzene. This would indicate that benzene is not unsaturated in the ordinary sense, and can be used as an argument in favour of Ladenburg's formula for benzene (Lossen, *A. 214, 129*; R. Schiff, *A. 220, 303*).

On the other hand, the S.V. of hexahydro-toluene (141.8) differs from that of toluene (118) by 23.8. This is about three times the difference (7.2) between the S.V. of pentane (117.2) and amylene (110). Hence it would appear that the change in the state of saturation in passing from hexahydro-toluene to toluene is of a similar character to the change in passing from pentane to amylene; the removal of  $H_2$  in both cases producing a diminution of between 7 and 8 units in the S.V. This supports Kekulé's formula for benzene (Lossen, *A. 225, 119*; Horstmann, *B. 20, 766*).

The refractive power of benzene is about equal to that calculated on the assumption that Kekulé's formula is correct, provided that certain assumptions are made regarding the connection between the refractive powers of compound molecules and the refractive powers of the constituent atoms (Brühl, *A. 200, 228*; Kanonnikoff, *J. R. 13, 473*).

Passing from physical to chemical considerations, we note first that the behaviour of benzene towards halogens is, on the whole, more like that of a saturated than an unsaturated compound. The following special arguments have also been employed. Sodium acting upon succinic ether gives succinyl-succinic ether, which loses  $H_2$  on oxidation, changing to di-oxyterephthalic ether. The formula of succinyl-succinic ether may be written in one of the following ways:

If the first correctly represents succinyl-succinic ether, it must be supposed to change into (II.), (III.), or (IV.) during the oxidation. The third formula would naturally lead to the formula

to the benzene formula  $\text{HC} \begin{array}{c} \text{CH=CH} \\ \text{CH=CH} \end{array} \text{CH}$  proposed by Wislicenus, a formula which would indicate the existence of two chloro-benzenes. The second formula

$\text{CO}_2\text{Et.C} \begin{array}{c} \text{C(OH)-CH} \\ \text{CH-C(OH)} \end{array} \text{C.CO}_2\text{Et on oxidation, a formula based upon Kekulé's ring. The fourth formula, like the third, leads to the benzene ring of Wislicenus. The fifth formula would lead to Kekulé's or Wislicenus' ring, but with the carboxyls in the ortho-position, whereas in terephthalic acid they are in the para-position. Ladenburg's formula for dioxy-terephthalic acid is$

of which from formulae I., II., III. or IV. requires the improbable assumption of a wandering of hydroxyl such as takes place when salicylic acid changes to *p*-oxy-benzoic acid. Ladenburg's formula can be derived from V, but only by assuming a rearrangement of the unsaturated unions.

By the action of sodium upon malonic ether a tricarboxylic ether,

is found to be phloroglucin tri-carboxylic ether,

favours Kekulé's hypothesis, especially when it is remembered that phloroglucin,

as well known to some extent, in spite of the great number of researches carried out on the benzene derivatives, the constitution of benzene itself still remains unsettled.

*Recent discussions on the Benzene formula.*—Ladenburg, B. 19, 971; 20, 62; Baeyer, B. 19, 1797; A. K. Miller, C. J. 61, 208; Thomsen, B. 19, 2944; Claus, B. 20, 1422.

#### Orientation.

Benzene gives rise to only one mono-substitution product. It gives three di-substitution products, and these, assuming either Kekulé's or Ladenburg's formula, are named as follows:

- 1, 2 = 1, 6 is called *ortho*,  
1, 3 = 1, 5 " " *meta*,  
1, 4 " " *para*.

When we come to tri-substitution products we must distinguish several cases.—1. Compounds of the formula  $\text{C}_6\text{H}_3\text{A}_3$ , that is to say, where the three substituting elements or radicles are all alike. There are three such compounds.

- 1, 2, 3 is called *consecutive*,  
1, 3, 5 " " *symmetrical*,  
1, 2, 4 " " *irregular*.

2. Compounds of the formula  $\text{C}_6\text{H}_4\text{AB}_2$ . There are six such compounds.—3. There are ten compounds of the formula  $\text{C}_6\text{H}_3\text{ABC}$ .

In the case of tetra-derivatives of benzene: 1. There are three compounds of the formula  $\text{C}_6\text{H}_2\text{A}_4$ :

- 1, 2, 3, 4 is called *consecutive*,  
1, 2, 4, 5 " " *symmetrical*,  
1, 2, 3, 5 " " *irregular*.

2. There are seven compounds of the formula  $\text{C}_6\text{H}_3\text{AB}_3$ .—3. There are thirteen compounds of the formula  $\text{C}_6\text{H}_2\text{A}_2\text{B}_2$ .—4. There are sixteen compounds of the formula  $\text{C}_6\text{H}_3\text{ABC}_2$ .—5. There are thirty compounds of the formula  $\text{C}_6\text{H}_2\text{ABCD}$ .

There is only one penta-derivative of the formula  $\text{C}_6\text{H}\text{A}_5$ , and only one compound of the formula  $\text{C}_6\text{A}_6$ .

The next question is how to determine, in a given case, the position of substituting radicles in the benzene ring. In isolated cases it is frequently found that this may be settled by special considerations, but the only general method known is that which was thoroughly worked out, by Kekulé's pupil Körner, in a most laborious research, in the course of which he discovered no less than 126 new compounds (G. 4, 305). This research has done more than anything else towards establishing the ring formula for benzene.

Suppose we convert  $\text{C}_6\text{H}_5\text{Br}_2$  into  $\text{C}_6\text{H}_3\text{Br}_2$ ; by reference to a figure it will be found that we can introduce a bromine atom in place of an atom of hydrogen in *ortho*-dibromobenzene in such a way as to produce either a consecutive or an irregular tribromobenzene, but not so as to produce a symmetrical product.

*Meta*-dibromobenzene can give rise to consecutive, irregular, or symmetrical, tribromobenzene, while *para*-dibromobenzene can only give rise to an irregular tribromobenzene.

An unknown dibromobenzene is therefore *para*-, *ortho*- or *meta*-, according as we can get one, two, or three tribromobenzenes by treating it with bromine. Thus the dibromobenzene from dibromoaniline gives rise to three tribromos.

benzene; therefore it is a *meta*-compound. Again, the chief product of the action of two molecules of bromine upon benzene gives rise to only one tribromobenzene on further treatment with bromine; hence this product is *para*-dibromobenzene. On the other hand, the minor product of the dibromination of benzene gives rise to two, and only two, tribromobenzenes; therefore it is *ortho*-dibromobenzene.

In order to investigate the constitution of a given tribromobenzene, two methods may be followed: either introduce another atom of bromine in place of hydrogen and see how many tetrabromobenzenes result, or displace an atom of bromine by hydrogen and carefully examine how many dibromobenzenes are formed. It can easily be seen by reference to the formula that consecutive tri bromobenzene produces two dibromobenzenes and also two tetrabromobenzenes, while symmetrical tri bromobenzene produces one dibromo- and one tetrabromo- benzene, and irregular tri bromobenzene gives rise to all three dibromobenzenes and all three tetrabromobenzenes.

The following are the melting and boiling points of the bodies described:

#### Dibromobenzenes.

Ortho . . . . .	[ -1° ] (224°)
Meta . . . . .	liquid (220°)
Para . . . . .	[ 89° ] (219°)

#### Tribromobenzenes.

Consecutive . . . . .	[ 87° ]
Symmetrical . . . . .	[ 120° ] (278°)
Irregular . . . . .	[ 44° ] (276°)

#### Tetrabromobenzenes.

Consecutive (1, 2, 3, 4) . . . . .	[ 160° ]
Symmetrical (1, 2, 4, 5) . . . . .	[ 137°-140° ]
Irregular (1, 2, 3, 5) am. . . . .	[ 99° ] (329°)

It will be observed that the isomerides differ widely in melting-points, but very slightly in boiling-points, and this is usually the case where isomerism is due to difference of position of substituents in the benzene nucleus.

The orientation of any given benzene derivative must be determined either by preparing it from one of the three bromobenzenes, or else by preparing a bromobenzene from it.

#### Examples.

*Para*-dibromobenzene when treated with sodium and methyl iodide gives a dimethylbenzene or xylene:  $C_6H_4Br_2 + 2CH_3I + 4Na \rightarrow 2NaI + 2NaBr + C_6H_4(CH_3)_2$ . By oxidation this is converted first into toluic acid,  $C_6H_4(CH_3)CO_2H$ , and next into terephthalic acid,  $C_6H_4(CO_2H)_2$ . It is therefore evident that the xylene, the toluic acid, and terephthalic acid, are all *para*-compounds. Also since a certain bromotoluene,  $C_6H_4Br(CH_3)$ , when treated with sodium and methyl iodide gives the above *para*-xylene, it must be the *para*-bromotoluene, and the bromobenzoic acid derived from it by oxidation— $C_6H_4BrCH_3 + O_2 \rightarrow C_6H_4Br.CO_2H + H_2O$ —must be *para*-bromobenzoic acid.

As another example we may take the *ortho*-series. A certain bromoaniline,  $C_6H_4Br.NH_2$ , is known to be *ortho*- because when the amidogen is displaced by bromine the product is *ortho*-dibromobenzene. Now, this *ortho*-bromoaniline

may be got by reducing a tribromobenzene  $C_6H_3Br_3(NO_2)$ , which may be formed by diazo-reaction from a nitroaniline  $C_6H_5(NH_2)(NO_2)$ , and this may be got by acting on a nitroanisol  $C_6H_4(OCH_3)(NO_2)$  by ammonia, and this nitroanisol may be obtained from a nitrophenol  $C_6H_4(OH)(NO_2)$ , and this nitrophenol may be itself reduced to an amidophenol  $C_6H_4(OH)(NH_2)$ , and this amidophenol may be converted by diazo-reaction into a chlorophenol  $C_6H_4(OH)Cl$ , and this chlorophenol may be converted by cautious fusion with potash into a dioxybenzene  $C_6H_4(OH)_2$ . All the compounds here enumerated are clearly *ortho*- compounds, and as the dioxybenzene is found to be pyrocatechin, we have proved that pyrocatechin is *ortho*-dioxybenzene.

In the *para*- series we may trace, in the same way, the connection between *p*-dibromobenzene and *p*-nitroanisol  $C_6H_4(OCH_3)NO_2$ . Thence we proceed by the following steps: reduce to  $C_6H_4(OCH_3)(NH_2)$ , convert this into  $C_6H_4(OCH_3)(OH)$  by nitrous acid, and treat with hydric iodide. In this way we get a second dioxybenzene, which is found to be hydroquinone, and this body is therefore a *para*-compound. The remaining dioxybenzene is resorcin, which must be the *meta*-compound.

The rules governing substitution in the benzene molecule are discussed in the article ANOMATIC SERIES. Derivatives of benzene are described, as ANILINE, PHENOL, BROMO-, BROMO-NITRO-, CHLORO-, CHLORO-NITRO-, IODO-, METHYL-, NITRO-, OXY- BENZENE, etc.

**BENZENE HEXABROMIDE**  $C_6H_2Br_6$ . Bromine is dropped into boiling benzene exposed to direct sunlight; the hexabromide crystallises out on cooling; it is separated from tri-bromobenzene by sublimation, and finally crystallised from a mixture of alcohol and benzene (Mitscherlich, P. 35, 374; Meunier, C. R., 101, 378; A. Ch. [6] 10, 269). Prisms, isomorphous with the (α)-hexachloride; not attacked by  $HNO_3$  or  $H_2SO_4$ . Alcoholic KOH splits it up into HBr and *n*-tri-bromo-benzene. If the product of the action of  $ZnEt_2$  upon benzene hexabromide dissolved in benzene be oxidised with chromic-mixture, benzoic, isophthalic, terephthalic, and di-bromobenzoic acids are formed (Ador & Gilliet, Bl. [2] 24, 486).

**BENZENE CARBOXYLIC ACIDS** v. BENZOIC, PHTHALIC, Tri-MELLITIC, Tri-MERIC, Semi-MELLITIC, PREHNITIC, PYROMELLITIC, MELLOPHANIC, and MELLITIC ACIDS.

**Benzene penta-carboxylic acid**  $C_6H_5CO_5$ , i.e.  $C_6H(CO_2H)_5$ . Formed by oxidation of penta-methyl benzene (Friedel & Crafts, A. Ch. [6] 1, 474). Amorphous (containing 6a<sub>q</sub>). The K salt forms small deliquescent prisms; the salts of Ag, Pb, Ba, Fe, Cu, and Al form insoluble pps.

**BENZENE (α)-HEXACHLORIDE**  $C_6H_2Cl_6$ . Mol. w. 291. [167]. S.G. 1.87. Prepared by chlorinating benzene in direct sunlight (Faraday, A. Ch. [2] 80, 275; Mitscherlich, P. 35, 370; Lesimple, Bl. [2] 6, 161); 850 g. may be got from 600 g. benzene (Leeds & Everhart, A. O. J. 2, 205). It may be freed from  $C_2HCl_3$  and  $C_6H_2Cl_4$  by treatment with  $H_2SO_4$  or  $HNO_3$  (Meunier, A. Ch. [6] 10, 223). Monoclinic crystals; may be sublimed. At 288° it boils, splitting up into HCl and (1, 2, 4)-tri-chloro-

benzene. The same decomposition is effected by heating with alcoholic KOH.

**Reactions.**—1. Zinc reduces it, in alcoholic solution, to benzene (Zinin, *Z.* 1871, 284).—2. Fuming nitric acid has no action.—3. Silver acetate forms crystalline  $C_6H_5Cl(OAc), C_6H_4Cl_2(OAc)_2$ .

**Benzene ( $\beta$ )-hexachloride**  $C_6H_2Cl_6$ . [310f]. V.D. 9.28. Formed at the same time as the ( $\alpha$ )-compound; when the mixture is sublimed, the ( $\beta$ )-compound sublimes last. If the mixture (4 pts.) be boiled with KCN (3 pts.) and alcohol, the ( $\beta$ )-compound is left while the ( $\alpha$ )-compound is decomposed. Regular octahedra, cubes, tetrahedra, or tetrakis-tetrahedra. Alcoholic potash splits it up into HCl and (1, 2, 4)-tri-chloro-benzene, but more slowly than the ( $\alpha$ )-compound (J. Meunier, *C. R.* 98, 436; 100, 358).

**BENZENE-HYDRAZIMIDO.** v. pp. 369, 370.

**BENZENE - PHENYL - HYDRAZIMIDO - NAPHTHALENE** v. *Benzene-azo-phenyl-( $\beta$ )-naphthylamine.*

**BENZENE-PYROCALLEOL-PHTHALEIN** v. *Tri - oxy - tri - phenyl - carbinol - carboxylic anhydride.*

**BENZENE-TRI-QUINONE**  $C_{24}O_4$  4aq. So-called 'oxy-carboxylic acid' of Lerch. [c. 95°]. **Formation.**—1. By the action of  $HNO_3$  upon the hydrochloride of tetra-oxy-di-amido-benzene; the yield is 65 p.c.—2. By the action of  $HNO_3$  upon di-imido-di-oxy-quinone  $C_6(NH)_2(OH)_2O_2$ .—3. By oxidation of hexa-oxy-benzene  $C_6(OH)_6$ .

**Properties.**—Colourless microscopic needles. Nearly insoluble in cold water, alcohol, and ether.

**Reactions.**—By reducing agents it is converted successively into di-oxy-benzene-di-quinone  $C_6(OH)_2O_2$ , tetra-oxy-benzene-quinone  $C_6(OH)_4O_2$ , and finally hexa-oxy-benzene  $C_6(OH)_6$ . On heating to 100° or on boiling with water it evolves  $CO_2$  and yields croconic acid  $C_4H_2O_5$  (Nietzki & Benckiser, *B.* 18, 504).

**BENZENE-RESORCIN PHTHALEIN** v. *Di-oxy - triphenyl - carbinol - carboxylic anhydride.*

**BENZENE - SULPH - AMIDO - ANILIDE** v. *BENZENE-SULPHONIC ACID.*

**BENZENE - SULPH - AMIDO - TOLUIDE** v. *BENZENE-SULPHONIC ACID.*

**BENZENE SULPHINIC ACID**  $C_6H_5SO_2H$  i.e.  $C_6H_5SO_2H$ . [84°].

**Formation.**—1. By adding zinc-dust to a cooled alcoholic solution of the chloride of benzene sulphonic acid; the resulting zinc salt is very slightly soluble in water; it is treated with  $Na_2CO_3$ ; the filtrate is concentrated and the acid ppt. by HCl (Schiller & Otto, *B.* 9, 1584).—2. From the phenyl-hydrazide of benzene sulphonic acid  $PhSO_2NHPh$ , called also di-phenyl-sulphazide, by boiling with baryta-water (Limpricht, *B.* 20, 1239).—3. By passing  $SO_2$  into a warm mixture of benzene and  $AlCl_3$  (Friedel & Crafts, *C. R.* 86, 1368; Adrianowsky, *B.* 12, 853).—4. By the action of  $ZnEt_2$  on  $C_6H_5SO_2Cl$  (Kalle, *A.* 119, 156).—5. From  $C_6H_5SO_2Cl$  and  $Pb(SEt)_2$ , thus:  $2PhSO_2Cl + 2Pb(SEt)_2 = (PhSO_2)_2Pb + PbCl_2 + 4SEt_2$  (Schiller & Otto, *B.* 9, 1636).—6. From diphenyl disulphide and alcohol potash:  $2Ph_2S_2 + 4KOH = PhSO_2K + 3PhSK + 2H_2O$  (S. a. O.).

**Properties.**—Long radiating prisms. Sl. sol. cold, v. sol. hot, water; v. sol. alcohol and

ether; acid to test-paper. Above 100° it decomposes.

**Reactions.**—1. Water at 180° gives benzene sulphonic acid and phenyl benzene-thiosulphonate (Otto, *A.* 145, 317); the same reaction takes place slowly in the cold, especially in presence of HCl (Pauly & Otto, *B.* 10, 2181).—2. Ethyl mercaptan at 100° gives di-ethyl disulphide and phenyl-ethyl di-sulphide (Otto & Rössing, *B.* 19, 3136).—3. Phosphorus pentachloride reacts thus:  $PhSO_2H + PCl_5 = PCl_3 + HCl + PhSO_2Cl$ .—4. Potash fusion gives benzene and  $K_2SO_4$ .—5. Sodium chloroacetate gives phenyl-sulphonyl-acetic acid,  $PhSO_2CH_2CO_2H$ .—6. Sodium di-chloroacetate gives phenyl-chloro-methyl sulphone  $PhSO_2CH_2Cl$ .—7. Methylene iodide reacts thus:  $CH_2I_2 + PhSO_2Na = NaI + PhSO_2CHI_2$ .—8. Sodium  $\alpha$ -di-chloro-propionate acting upon sodium benzene sulphonate gives di-phenyl ethylene di-sulphone,  $PhSO_2C_2H_4SO_2Ph$ .—9. Phenyl-hydrazine in presence of conc.  $HClAq$  forms phenyl benzene-thiosulphonate and the phenyl hydrazide of benzene sulphonic acid (q. v.).—10. When  $H_2SO_4$  is added to a solution of  $PhSO_2Na$  and  $NO_2Na$  a pp. is got which may be crystallised from alcohol. It is perhaps  $(PhSO_2)_2NOH$ . It is sl. sol. cold, water,  $CS_2$ , or ligroin, but v. sol. alcohol and ether. At 100° it evolves nitrous acid gas. Boiling water, alkalis, or acids, decompose it into  $PhSO_2H$  and nitrous acid (Königs, *B.* 11, 615).—11. Fuming nitric acid forms  $C_6H_5NSO_3$ , which may be  $(PhSO_2)_2NO$ . It forms crystals, [98.5°], insol. alkalis, sl. sol. alcohol, m. sol. benzene (Otto & Gruber, *A.* 141, 370; Königs, *B.* 11, 615, 1590).

**Salts.**— $BaA'$ : clumps.— $ZnA'$ : tablets, sl. sol. alcohol and ether, sl. sol. water (Kalle).— $ZnA', 2aq$ : insol. cold water (S. a. O.).— $AgA'$ .

**Ethyl ether  $EtA'$ .**—Formed by means of  $EtOH$  and HCl, or, together with  $CO_2$ , by heating  $PhSO_2Na$  with  $ClCO_2Et$ . Non-volatile oil.  $KMnO_4$  in acetic acid solution oxidises it to  $PhSO_3Et$  (Otto & Rössing, *B.* 18, 2495; 19, 1225).

**Benzene di-sulphinic acid**  $C_6H_5(SO_2H)_2$  [1.3]. From [1.3]  $C_6H_5(SO_2Cl)_2$  and zinc-dust (Pauly, *B.* 9, 1595). Oil.— $BaA''$ .

**BENZENE-SULPH-NITR-ANILIDE** v. *BENZENE-SULPHONIC ACID.*

**BENZENE SULPHONE** v. *DI-PHENYL-SULPHONE.*

**BENZENE SULPHONIC ACID**  $C_6H_5SO_3H$  i.e.  $C_6H_5SO_3H$ . Phenyl-sulphurous acid. Sulphobenzotic acid. [42°].

**Formation.**—1. From benzene and fuming  $H_2SO_4$  (Mitscherlich, *P.* 31, 283, 634; Stenhouse, *Pr.* 14, 351; Wurtz, *C. R.* 64, 749).—2. By the oxidation of benzene sulphonic acid (Otto & Ostrop, *A.* 141, 369).—3. By the oxidation of phenyl mercaptan:  $PhSH + O = PhSO_2H$  (Vogt, *A.* 119, 151).—4. By boiling  $p$ -diazobenzene sulphonic acid with alcohol under pressure (R. Schmitt, *A.* 120, 129).—5. Together with phenyl benzene-thiosulphonate by heating benzene sulphonic acid with water at 180° (Otto, *A.* 145, 317):

**Preparation.**—Benzene (2 pts.) is shaken with fuming  $H_2SO_4$  (3 pts.) with gentle warm-

ing. The acid is separated from undissolved benzene, diluted, and neutralised with  $\text{BaCO}_3$  or lead carbonate. In the filtrate the Ba, or Pb, salt is decomposed by  $\text{H}_2\text{SO}_4$  or  $\text{H}_2\text{S}$  respectively.

**Properties.**—Small, four-sided, deliquescent plates (containing 1 aq).

**Reactions.**—1. By fusion with potash, soda, or a mixture of the two, it is converted into phenol. The percentage of phenol obtained increases with the amount of alkali and with the temperature of the fusion. The percentage of phenol is given in this table; one equivalent of acid being used:

KOH	NaOH	Temperature	Phenol
2	—	253°	23
3	—	210°	7
8	—	267°	79
—	3	209°	1
—	3	280°	26
8	3	211°	2
3	3	277°	89
3	3	360°	64
7	—	252°	96

(P. Degener, *J. pr.* 125, 401).—2. The potassium salt distilled with KCN or  $\text{K}_2\text{FeCy}_4$  gives benzonitrile (Merz, *Z.* [2] 5, 33). 3. Dry distillation gives  $\text{H}_2\text{SO}_4$ , benzene,  $\text{SO}_2$ , and di-phenylsulphone.—4. Dry distillation of the ammonium salt gives benzene and small quantities of benzene sulphamide, diphenyl, di-phenyl sulphone, phenyl mercaptan, and (traces of) quinoline (Egli, *B.* 18, 575).—5. The potassium salt distilled with  $\text{NaNH}_2$  gives aniline (Jackson a. Wing, *Am.* 9, 75).—6. Distillation of the Na salt gives di-phenyl sulphide, di-phenyl di-sulphide, phenyl mercaptan,  $\text{CO}_2$ , and  $\text{SO}_2$  (Stenhouse).—7. A mixture of  $\text{H}_2\text{SO}_4$  and water boiling at 175° converts it into benzene and  $\text{H}_2\text{SO}_4$  (Armstrong, *C. J.* 45, 151).—8. Fusion with potassium formate gives potassium benzoate.

**Salts** (Freund, *A.* 120, 76; Kalle, *A.* 119, 161).— $\text{BaA}$ , aq: pearly plates, al. sol. alcohol.— $\text{CuA}$ , 6aq: large blue tables, sol. alcohol.— $\text{AgA}$ , 8aq: tables.— $\text{ZnA}$ , 6aq: six-sided tables.

**Methyl ether**  $\text{MeA}$ . S.G. 1.27. Formed by action of  $\text{NaOMe}$  upon  $\text{PhSO}_2\text{Cl}$  in ether (H. Hübner, *A.* 223, 235). Oil.

**Ethyl ether**  $\text{EtA}$ . S.G. 1.22. From  $\text{NaOEt}$  and  $\text{PhSO}_2\text{Cl}$  in ether. Formed also by oxidising  $\text{PhSO}_2\text{Et}$  (Otto a. Rössing, *B.* 19, 1225). Oil, miscible with alcohol, ether, and benzene. Saponified by boiling water.

**Propyl ether**  $\text{PrA}$ . S.G. 1.179 (H.).

**Phenyl ether**  $\text{PhA}$ . [85°]. Formed by acting upon  $\text{PhSO}_2\text{Cl}$  dissolved in benzene with sodium-phenol. Formed also by action of zinc-dust on a mixture of phenol and  $\text{PhSO}_2\text{Cl}$ . Trimetric crystals,  $a:b:c = .6847:1: .8576$ . V. sol. benzene, ether, and alcohol, insol. water. Slowly saponified by boiling aqueous KOH; alcoholic  $\text{NH}_3$  even at 200° does not affect it. On nitration it gives the nitro-phenyl ether, and also a tri-nitro- derivative [116°] (Schiaparelli, *G.* 11, 66; R. Otto, *B.* 19, 1832).

**p-Nitro-phenyl ether**  $\text{C}_6\text{H}_4\text{SO}_2\text{C}_6\text{H}_4(\text{NO}_2)$ . [82°]. Formed by nitrating the preceding; or from p-nitro-phenol,  $\text{ZnCl}_2$ , and  $\text{PhSO}_2\text{Cl}$  (Schiaparelli, *G.* 11, 70). Sl. sol. cold alcohol.

**Chloride**  $\text{PhSO}_2\text{Cl}$ .—Benzene sulphonylchloride.

[84°]. S.G. 1.578. Formed by the action of  $\text{PCl}_5$  on a salt of benzene sulphonic acid (Gerhardt a. Chancel, *C. R.* 85, 690), or by passing chlorine into an aqueous solution of  $\text{PhSO}_2\text{H}$  (Otto a. Ostrop). Oil; v. sol. alcohol and ether. Slowly solidifies at 0° forming large rhombic crystals. May be distilled in vacuo, but is much decomposed on boiling under atmospheric pressure. Hardly attacked by water.

**Reactions.**—1.  $\text{TiCl}_4$  and  $\text{HCl}$  form phenyl mercaptan.—2. Sodium amalgam or  $\text{ZnEt}_2$  forms a benzene sulphinate.—3.  $\text{PCl}_5$  at 210° gives  $\text{C}_6\text{H}_5\text{Cl}$ , phosphorus oxychloride, and  $\text{SO}_2\text{Cl}_2$  (Kekulé a. Barbaglia, *B.* 5, 876).—4.  $\text{PhO}_2$  gives at 180°  $\text{PhSO}_2$  and  $\text{C}_6\text{H}_5\text{Cl}$  (Wallach, *A.* 214, 219).—5. Phenol (1 mol.) and zinc dust gives  $\text{PhSO}_2\text{Ph}$ ; phenol ( $\frac{1}{2}$  mol.) and  $\text{ZnCl}_2$  gives  $\text{PhSO}_2\text{C}_6\text{H}_4\text{O}_2\text{SO}_2\text{Ph}$  (?) [123°] (Schiaparelli, *G.* 11, 66).

**Bromide**  $\text{PhSO}_2\text{Br}$ . From  $\text{PhSO}_2\text{H}$  and  $\text{Br}$  (Otto, *A.* 141, 372). Oil.

**Amide**  $\text{PhSO}_2\text{NH}_2$ . Benzene sulphamide.

**Benzene sulphonamide**. [156°] (Hybbenet, *A.* 221, 206). S. 43 at 16°. Formed by the action of  $\text{NH}_3$  on the chloride or bromide (Otto a. Ostrop, *A.* 141, 365), or, in small quantities, by heating the ammonium salt at 200° (Stenhouse, *Pr.* 11, 351). Needles (from water) or plates (from alcohol). V. sl. sol. water, sol. hot  $\text{NH}_4\text{Aq}$ , v. sol. alcohol and ether. Ammoniacal  $\text{AgNO}_3$  gives a pp. of  $\text{PhSO}_2\text{NHAg}$ . With  $\text{PCl}_5$  the amide gives  $\text{PhSO}_2\text{NH}_2\text{PCl}_2$  [131°] (Wichelhaus, *B.* 2, 502). Succinyl chloride gives rise to  $\text{PhSO}_2\text{N}(\text{C}_6\text{H}_5)_2$  [160°], whence conc.  $\text{NH}_4\text{Aq}$  produces  $\text{PhSO}_2\text{N}(\text{C}_6\text{H}_5)_2\text{CO}_2\text{NH}_4$  [166°] (Gerhardt a. Chancel, *C. R.* 35, 690; Gerhardt a. Chiozza, *A. Ch.* [3] 47, 129).

**Benzoyl derivative**  $\text{PhSO}_2\text{NHPh}$ . [147°]. From benzene sulphonamide and  $\text{BzCl}$  at 145° (Gerhardt, *A.* 108, 214; Wallach, *A.* 214, 210). Prisms (from alcohol). Salt.  $\text{PhSO}_2\text{NNaBz}$ . Silky needles (from alcohol).

**Reactions.**—1.  $\text{PCl}_5$  gives the imido-chloride  $\text{PhSO}_2\text{N}=\text{CClPh}$  [80°]. This forms triclinic plates (from benzene)  $a:b:c = .862:1: .7$ ,  $\alpha = 87^\circ 59'$ ,  $\beta = 94^\circ 31'$ ,  $\gamma = 69^\circ 24'$ . When this imido-chloride is heated it splits up into benzonitrile and benzene sulpho-chloride (Wallach a. Gossmann, *A.* 214, 210). Aniline converts the imido-chloride into phenyl-sulphonyl-phenyl-benzamide ( $\text{PhSO}_2\text{N}(\text{C}_6\text{H}_5)_2$ ).—2. The Pb and Ag derivatives are converted by  $\text{EtI}$  at 100° into the original amide (Remsen a. Palmer, *Am.* 8, 235).

**Di-benzoyl derivative**  $\text{PhSO}_2\text{NBzPh}$ . [105°].

**Methylamide**  $\text{PhSO}_2\text{NHMe}$ . An oil, formed by treating the chloride with aqueous methylamine (Romburgh, *B.* 3, 16).

**Methyl-nitro-amide**  $\text{PhSO}_2\text{NMe}(\text{NO}_2)$ . [44°]. From the preceding and  $\text{HNO}_3$  (S.G. 1.46).

**Ethylamide**  $\text{PhSO}_2\text{NEt}$ . [58°]. From the chloride and  $\text{NEtH}_3$  (Romburgh, *B.* 3, 13).

**Ethyl-nitro-amide**  $\text{PhSO}_2\text{NEt}(\text{NO}_2)$ . [44°]. Formed by the action of  $\text{HNO}_3$  on the preceding or on the succeeding compound. Needles (from alcohol); volatile with steam.

**Di-methylamide**  $\text{C}_6\text{H}_5\text{SO}_2\text{NMe}_2$ . [48°].

**Di-ethylamide**  $\text{PhSO}_2\text{NEt}_2$ . [42°].

**Anilide**  $\text{PhSO}_2\text{NHPh}$ . [102°] (Wallach, *A.* 214, 221).

S. 43 at 16°. From the chloride and aniline (Biff, *A.* 91, 107; Gericks, *A.* 109, 217; Meyer a. Ascher, *B.* 4, 823).

**p-Chloro-anilide**  $\text{PhSO}_2\text{NH}_2\text{C}_6\text{H}_4\text{Cl}$  [187]. From the preceding and  $\text{PCl}_5$  or from  $\text{PhSO}_2\text{Cl}$  and *p*-chloro-aniline (Wallach a. Huth, B. 9, 425).

**o-Nitro-anilide**  $\text{PhSO}_2\text{NH}_2\text{C}_6\text{H}_4(\text{NO}_2)$  [1:2]. [104]. From *o*-nitro-aniline and  $\text{PhSO}_2\text{Cl}$  (Lellman, A. 221, 16; B. 16, 591). Yellow plates, sol. alcohol, glacial  $\text{HOAc}$ , and  $\text{CHCl}_3$ .

**m-Nitro-anilide**  $\text{PhSO}_2\text{NH}_2\text{C}_6\text{H}_4(\text{NO}_2)$  [1:8]. [132]. From *m*-nitro-aniline and  $\text{PhSO}_2\text{Cl}$ . Flat yellow needles (L.).

**p-Nitro-anilide**  $\text{PhSO}_2\text{NH}_2\text{C}_6\text{H}_4(\text{NO}_2)$  [1:4]. [139]. From *p*-nitro-aniline and  $\text{PhSO}_2\text{Cl}$ . Yellow crystals.

**o-Amido-anilide**  $\text{PhSO}_2\text{NH}_2\text{C}_6\text{H}_4(\text{NH}_2)$  [1:2]. [168]. From the *o*-nitro-anilide by tin and  $\text{HCl}$  (L.). Needles (from 50 p.c. alcohol). V. sol. alcohol, sl. sol. ligroin.— $\text{B}^*\text{HCl}$ .

**p-Toluide**  $\text{PhSO}_2\text{NH}_2\text{C}_6\text{H}_4\text{Me}$  [1:4]. [120]. From the chloride and *p*-toluidine (Wallach a. Huth, B. 9, 427).

**m-Nitro-p-toluide**  $\text{PhSO}_2\text{NH}_2\text{C}_6\text{H}_3(\text{Me})(\text{NO}_2)$  [1:4:3]. [99]. From the preceding by nitration; or from  $\text{PhSO}_2\text{Cl}$  and nitro-*p*-toluidine (Lellmann, A. 221, 18). Cubes (from alcohol). Not attacked by alcoholic  $\text{KOH}$ .

**Di-nitro-p-toluide**  $\text{PhSO}_2\text{NH}_2\text{C}_6\text{H}_3(\text{Me})(\text{NO}_2)_2$  [178]. Formed by nitration of the *p*-toluide. Yellow prisms, sl. sol. cold alcohol (Lellmann, B. 16, 595). Not attacked by alcoholic  $\text{KOH}$ .

**m-Amido-p-toluide**  $\text{PhSO}_2\text{NH}_2\text{C}_6\text{H}_3(\text{Me})(\text{NH}_2)$  [1:4:3]. [146:5]. From the nitro-compound by tin and  $\text{HCl}$ . Colourless needles (from dilute alcohol); sl. sol. water.

**di-phenyl-amide**  $\text{PhSO}_2\text{NPh}_2$  [124]. From  $\text{PhSO}_2\text{Cl}$  and  $\text{NIHPh}$ , at  $200^\circ$  (Wallach, A. 214, 220). Silk-like needles (from alcohol). Sol. alcohol, ether, or benzene, insol. water. Conc.  $\text{H}_2\text{SO}_4$  forms a blue solution. Insol.  $\text{HClAc}$ .

**Phenyl-hydrazide**  $\text{C}_6\text{H}_5\text{N}_2\text{O}_2\text{S}$  i.e.  $\text{PhSO}_2\text{NHNHPh}$ . **Phenyl-benzene-sulphazide**. **Di-phenyl sulphazide**. [148–150].

**Formation**.—1. By the action of  $\text{SO}_2$  upon diazo-benzene (Königs, B. 10, 1531; Wiesinger, B. 10, 1716).—2. From benzene sulphonic chloride and phenyl-hydrazine (Fischer, A. 190, 132).—3. From benzene-sulphonic acid (*q. v.*) and phenyl-hydrazine hydrochloride (Fischer, B. 18, 893).—4. By reduction of  $\text{C}_6\text{H}_5\text{N}_2\text{SO}_3\text{C}_6\text{H}_5$  with zinc dust and acetic acid.

**Preparation**.—Aniline is dissolved in alcohol saturated with  $\text{SO}_2$ ; the solution is cooled to  $-10^\circ$  and a conc. solution of about double the theoretical quantity of  $\text{KNO}_3$  is slowly added; after standing for 24–36 hours it is precipitated by water; the yield is 80 p.c. **Properties**.—White felted needles (from alcohol). With  $\text{NaOH}$  it gives a very unstable crystalline sodium compound  $\text{C}_6\text{H}_5\text{N}_2\text{SO}_3\text{Na}$ . **Reaction**.—By boiling with aqueous alkalis (i.e. baryta-water) it is decomposed into benzene sulphonic acid, benzene, and  $\text{N}_2$ ;  $\text{PhN}_2\text{H}_2\text{SO}_3\text{Ph} = \text{PhH} + \text{PhSO}_3\text{H} + \text{N}_2$  (E., B. 18, 893; Limpriht, B. 20, 1288).

**BENZENE-*o*-DISULPHONIC ACID**  $\text{C}_6\text{H}_4(\text{SO}_3\text{H})_2$  i.e.  $\text{C}_6\text{H}_4(\text{SO}_3\text{H})_2$  [1:2]. From amido-benzene *m*-sulphonic acid by sulphonation, diazotisation, and boiling with alcohol (Drebes, B. 9, 448).

**Chloride**  $\text{C}_6\text{H}_4(\text{SO}_2\text{Cl})_2$  [131].

**Amide**  $\text{C}_6\text{H}_4(\text{SO}_2\text{NH}_2)_2$  [233]. **Benzene-*m*-disulphonic acid**  $\text{C}_6\text{H}_4(\text{SO}_3\text{H})_2$  [1:8].

**Formation**.—From amido-benzene *p*-sulphonic acid by sulphonation, diazotisation, and heating with alcohol (Zander, A. 198, 8).

**Preparation**.—When benzene or benzene sulphonic acid is treated with fuming  $\text{H}_2\text{SO}_4$ , both *m* and *p* disulphonic acids are formed. The *m* acid is formed chiefly when the temperature is low or when the mixture is kept at a high temperature for a short time only (Buckton a. Hofmann, C. J. 9, 255; Barth a. Senhofer, B. 8, 754, 1477; 9, 969; Limpriht, B. 9, 650; Körner a. Monselise, B. 9, 583). Benzene (1 pt.) is freed from thiophene by shaking with conc.  $\text{H}_2\text{SO}_4$ , and is then dissolved in fuming (70 p.c.) sulphuric acid (4 pts.) at  $40^\circ$ . The solution is heated for 2 hours at  $275^\circ$ ; cooled; poured into water, and neutralised with lime;  $\text{CaSO}_4$  is removed by filtration, and the lime salts of the *m* and *p* acid may be separated by crystallisation, the former separating first (Binschedler a. Busch, *Monit. Scient.* 1878, 1169; cf. Egli, B. 8, 817; Heinzelmann, A. 188, 159).

**Properties**.—Very deliquescent crystals (containing 2 aq.). The alkaline salts are v. sol. water.

**Salts**.— $\text{Na}_2\text{A}^*$  4aq.— $\text{K}_2\text{A}^*$  aq. S. 66.6 at  $100^\circ$ .— $\text{BaA}^*$  2aq. S. 44.2 at  $100^\circ$ . Large prisms.— $\text{CuA}^*$  6aq. v. sol. water.— $\text{CaA}^*$  1 aq.— $\text{ZnA}^*$  4aq.— $\text{PbA}^*$  2aq. S. (of  $\text{PbA}^*$ ) 86.2 at  $26^\circ$ .— $\text{Ag}_2\text{A}^*$ .

**Reaction**.—1. By fusion with potash or soda it is converted into resorcin. The acid is first converted into *m*-phenol sulphonic acid (at  $180^\circ$ ). The amount of resorcin formed by fusing this body (1 mol.) with potash (21 mols.) at  $270^\circ$  for 10 minutes is 2.7 p.c., at  $270^\circ$  for 20 minutes it is 21 p.c., and at  $250^\circ$  for 30 minutes it is 26 p.c. When soda, or a mixture of potash and soda, is used, the yield is rather less (Degener, J. pr. 128, 318).—2. By fusion with potassium cyanide the potassium salt is converted into  $\text{C}_6\text{H}_4(\text{CN})_2$ , which, when boiled with potash, gives isophthalic acid (Wislicenus a. Brunner, B. 4, 984; Ross-Garrick, Z. 5, 549; Barth a. Senhofer, A. 174, 238; B. 8, 754; V. Meyer a. Michler, B. 8, 672).

**Chloride**  $\text{C}_6\text{H}_4(\text{SO}_2\text{Cl})_2$  [63]. From sodium benzene disulphonate and  $\text{PCl}_5$  or  $\text{S}_2\text{O}_2\text{Cl}_2$  (Heumann a. Köchlin, B. 16, 483). Monosymmetrical crystals, *abc* = 1.1991 : 1 : 0.8688,  $\beta = 85^\circ 44'$  (Otto, B. 19, 2424).

**Amide**  $\text{C}_6\text{H}_4(\text{SO}_2\text{NH}_2)_2$  [229]. Needles. **Benzene-*p*-disulphonic acid**  $\text{C}_6\text{H}_4(\text{SO}_3\text{H})_2$  [1:4]. Prepared as above. The potassium salt distilled with KCN gives di-cyano-benzene, which, on saponification, gives terephthalic acid (Wislicenus a. Brunner, B. 4, 984).

**Salts**.— $\text{K}_2\text{A}^*$  aq. thin plates. S. (of  $\text{K}_2\text{A}^*$ ) 66.6 at  $100^\circ$ .— $\text{BaA}^*$  aq. S. (of  $\text{BaA}^*$ ) 7.19 at  $100^\circ$ .— $\text{CaA}^*$  aq.— $\text{CuA}^*$  4aq.— $\text{PbA}^*$  aq. S. (of  $\text{PbA}^*$ ) 24.9 at  $26^\circ$ .— $\text{ZnA}^*$  4aq.

**Chloride**  $\text{C}_6\text{H}_4(\text{SO}_2\text{Cl})_2$  [131]. Needles. **Amide**  $\text{C}_6\text{H}_4(\text{SO}_2\text{NH}_2)_2$  [268]. Thin scales (from water).

**Benzene-tri-sulphonic acid**  $\text{C}_6\text{H}_3(\text{SO}_3\text{H})_3$  [1:3:5]. Prepared by heating 5 pts. of the potassium salt of the mono-*o*-disulphonic acid with 2

pts. of ordinary  $H_2SO_4$  in an open dish till  $H_2SO_4$  volatilises; this ready sulphonation is probably due to the presence of  $KHSO_3$  or of potassium pyrosulphate. By heating the potassium salt with KCN the nitrile of trimesic acid  $C_3H_2(CO_2H)_3$  is obtained. NaOH fusion yields phloroglucin. The Ba salt is sparingly soluble in water.

**Salts.**— $K_2A''3aq.$ — $Ba_2A''4.$ — $Ba_3A''6aq.$ — $Pb_2A''4aq.$ : slender needles, v. sol. water.— $Ag_2A''8aq.$  (Senhofer, *A.* 174, 213).

**Chloride:** [184°]. **Amide:** [306°] (Jackson a. Wing, *B.* 19, 898).

**Benzoyl-amide**  $C_6H_5(SO_2NHBz)$ , [285°]. **Anilide**  $C_6H_5(SO_2NPh)$ , [237°] (*J. Am. C.* 346).

**Derivatives of the sulphonic acids of benzene** are described as—**DIAZOBENZENE SULPHONIC ACID** (p. 405), **SULPHO-BENZENE-AZOXY-BENZENE SULPHONIC ACID** (p. 428), **AMIDO-, BROMO-, BROMO-AMIDO-, BROMO-NITRO-, CHLORO-, IODO-, METHYL-, NITRO-, PROPYL-, BENZENE SULPHONIC ACIDS.**

**BENZENE DI-SULPHOXIDE** v. PUENTL **BENZENE-THIOSULPHONATE.**

**BENZENE SULPHYDRATE** v. PHENYL MERCAPTAN.

#### **BENZENE THIOSULPHONIC ACID** $C_6H_5SO_2SH$ .

**Preparation.**—1. By the action of KHS on benzene-sulphonic chloride. —2. By heating a solution of a salt of benzene-sulphinic acid with sulphur.

**Salts.**— $KA'$ : v. sol. hot alcohol and water.— $NaA'11aq.$

**Ethyl ether**  $C_6H_5SO_2SEt$ . **Ethyl-phenyl-di-sulphoxide.** From the potassium salt and  $EtBr$ . Colourless heavy oil. Insol. water, miscible with alcohol and ether. Slowly volatilises with steam. On reduction with zinc and  $H_2SO_4$  in alcoholic solution it gives phenyl mercaptan and ethyl mercaptan. Boiling  $KOHAq$  gives benzene sulphinic acid and di-ethyl di-sulphide (Otto, *B.* 15, 127).

**Ethylene ether**  $A'_2C_2H_4$ : [85°]. Formed by heating an alcoholic solution of the Na or K salt (2 mols.) with ethylene bromide (1 mol.). Small thin silky needles. Without taste or smell. V. sol. benzene and hot alcohol, far less in cold alcohol. By warming with alcoholic KOH it gives benzene sulphinic acid, ethane di-sulphinic acid  $C_2H_4(SO_2H)_2$ , and di-ethylene tetra-sulphide  $(C_2H_4)_2S_4$ . By warming with alcoholic KIHS it gives the potassium salt and ethylene mercaptan  $C_2H_4(HS)_2$ . If the alcoholic solution is warmed with ethylene mercaptan, benzene sulphinic acid and di-ethylene tetra-sulphide are produced. On reduction it gives primarily benzene sulphinic acid and ethylene mercaptan. By warming with alcoholic  $H_2S$  it is converted into phenyl tetra-sulphide, ethylene sulphydrate, &c. (Otto a. Bössing, *B.* 20, 2079, 2090).

**Phenyl ether**  $C_6H_5SO_2SC_6H_5$ . **Benzene di-sulphoxide. Diphenyl di-sulphoxide.** [45°]. Formed by the decomposition of benzene sulphinic acid (q. v.) by boiling water, or even by spontaneous decomposition (Pauly a. Otto, *B.* 9, 1639; 10, 2181; 11, 2070). Monosymmetrical prisms,  $a:b:c=1.446:1.14709$  (Otto, *B.* 15, 131). **Reactions.**—1. By saponification with alkalis it is decomposed into benzene sulphinic acid and di-phenyl-di-sulphide:

$2C_6H_5SO_2H + (C_6H_5)_2S$ . This probably takes place in two stages:

The benzene-thiosulphonic-phenyl-ether reacts in the cold with sodium phenyl mercaptide according to the last equation (b) (Otto a. Bössing, *B.* 19, 1236). —2. **Zinc-dust** added to an alcoholic solution gives zinc phenyl mercaptide and zinc benzene sulphinate. —3.  $H_2S$  forms benzene sulphinic acid, phenyl mercaptan, phenyl tetra-sulphide, &c. —4. **Zinc phenyl mercaptide** added to an alcoholic solution gives di-phenyl di-sulphide and zinc benzene sulphinate. —5. **Phenyl mercaptan** on heating forms di-phenyl di-sulphide and benzene sulphinic acid. —6. **Ethyl mercaptan** at 115° gives di-ethyl di-sulphide, phenyl-ethyl disulphide, di-phenyl di-sulphide, and other products (Otto a. Bössing, *B.* 19, 3137).

**BENZENYL ALCOHOL** v. **Ortho-BENZOIS ACID.**

#### **BENZENYL-AMIDINE** v. **BENZAMIDINE.** **BENZENYL-TRI-AMIDO-BENZENE**

$C_6H_5N$ , i.e.  $Ph.C \begin{smallmatrix} \text{NH} \\ \text{N} \end{smallmatrix} > C_6H_5.NH_2$ . [240°].

**Amido-phenylene-benzamidine.** From benzenyl-nitro-phenylene-diamine, tin, and  $HCl$  (Hübner, *A.* 208, 809). Needles, v. al. sol. water, v. sol. alcohol. — $B''2HCl$ . — $B''2HNO_2$ . — $B''H_2SO_4$  2aq.

**Benzoyl derivative**

$Ph.C \begin{smallmatrix} \text{NH} \\ \text{N} \end{smallmatrix} > C_6H_5.NHBz$ . [125°–214°]. From di-benzoyl-nitro-phenylene-diamine dissolved in  $HOAc$  by boiling with tin and  $HCl$  (Hübner, *B.* 14, 2653). Plates (containing aq. from dilute alcohol).  $H'IHCl$ : needles.

#### **BENZENYL-(β)-AMIDO-α-NAPHTHOL**

$C_{10}H_7NO$  i.e.  $C_{10}H_7 \begin{smallmatrix} O \\ \text{N} \end{smallmatrix} > C.C_6H_5$ , [122°]. Prepared by reduction of the benzoyl-derivative of α-nitroso-(α)-naphthol (Worms, *B.* 15, 1816). Colourless needles. Sublimable. Sol. alcohol and acetic acid, al. sol. water.

**Benzenyl-(α)-amido-(β)-naphthol**

**Formation.**—1. As a by-product in the reduction of α-nitro-(β)-naphthyl-benzoate. —2. By heating benzoyl-amido-(β)-naphthol. (Böttcher, *B.* 10, 1936; *C. C.* 1881, 898).

**Properties.**—Long colourless needles. Sublimable. V. o. sol. alcohol, ether, and benzene, al. sol. petroleum-ether, insol. water. Dissolves in strong acids. Its solutions have a beautiful blue fluorescence.  $B'H_2Cl$ ,  $PtCl_4$ : yellow needles.

#### **BENZENYL-(α)-AMIDO-NAPHTHYL MERCAPTAN**

$C_{10}H_7 \begin{smallmatrix} S \\ \text{N} \end{smallmatrix} > C.C_6H_5$ , [103°]. Formed by heating benzoyl-(α)-naphthylamine (3 pts.) with sulphur (1 pt.) for two hours (yield 10 p.c.) (Hofmann, *B.* 20, 1798). Obtained also by oxidation of the thiobenzoyl derivative of α-naphthylamine  $C_{10}H_7.N.C(SH).C_6H_5$  with potassium ferricyanide (Jacobsen, *B.* 20, 1866). Glistening colourless needles from alcohol. V. sol. ether, benzene, and hot alcohol. Very weak base.

orange needles.

**Benzoyl- $(\beta)$ -amido-naphthyl mercaptan**

$C_{10}H_7NS$  i.e.  $C_6H_5\langle\begin{smallmatrix} N \\ S \end{smallmatrix}\rangle C_6H_4$  [107°]. Prepared by heating benzoyl- $(\beta)$ -naphthylamine with sulphur. Felted needles.— $B'H_2Cl$ ,  $PtCl_4$  (Hofmann, B. 20, 1803).

**BENZENYL-AMIDO-PHENANTHROL** v. PHENANTHRENE.

**BENZENYL- $\alpha$ -AMIDO-PHENOL**  $C_{12}H_9NO$  i.e.

$Ph.C\langle\begin{smallmatrix} O \\ N \end{smallmatrix}\rangle C_6H_4$  [103°]. (c. 315°). From  $\alpha$ -amido-phenol and  $BzCl$  or phthalic anhydride (Ladenburg, B. 9, 1526). Plates (from dilute alcohol). Insol. water, sol. dilute  $H_2SO_4$ . Split up by  $HCl$  at 130° into benzoic acid and  $\alpha$ -amido-phenol. Its salts are decomposed by water.— $B'H_2PtCl_6$ .

**BENZENYL-DIAMIDO-DIPHENYL**  $C_{14}H_{11}N_2$  i.e.  $C_6H_5.C\langle\begin{smallmatrix} N \\ NH \end{smallmatrix}\rangle C_6H_4.C_6H_5$  [198°]. From

benzoyl-nitro- $p$ -amido-diphenyl, tin, and glacial  $HOAc$  (Hübner, A. 209, 347). Plates (from alcohol).— $B'HCl$ .— $B'H_2PtCl_6$ .— $B'H_2SO_4$ .

**BENZENYL-AMIDO-PHENYLENE** DIAMINE v. BENZENYL-THI-AMINO-BENZENE.

**BENZENYL-AMIDO-PHENYL MERCAPTAN**

$C_{10}H_7NS$  i.e.  $[1:2] C_6H_4\langle\begin{smallmatrix} N \\ S \end{smallmatrix}\rangle C_6H_5$  [c. 360°].

**Formation.**—1. By heating amido-phenyl mercaptan with  $BzCl$ , with benzoic aldehyde (probably benzyl alcohol is also formed), or with benzonitrile ( $NH_3$  being evolved).—2. By heating phenyl-amido-acetonitrile with sulphur ( $H_2S$  and  $HCN$  being evolved).—3. In small quantity by the action of benzoyl chloride on methenyl-amido-phenyl mercaptan.—4. From thio-benzoic anilide and alkaline  $K_2FeCy_4$  (Jacobsen, B. 19, 1068).

**Preparation.**—Benzanilide (2 pts.) is heated with  $S$  (1 pt.) for a few hours to boiling. The yield is 50 to 60 p.c. of the benzanilide used.

**Properties.**—Needles. Weak base. Sol. alcohol, ether,  $CS_2$  and  $HClAq$ . Has a pleasant smell of tea-roses and geraniums. It remains almost unaltered on boiling with aqueous acids or alkalis. On fusion with  $KOH$  it is decomposed into benzoic acid and  $\alpha$ -amido-phenyl mercaptan. Salt.— $BH[AuCl]$ .

**References.**—Hofmann, B. 12, 2359; 13, 7, 1286; Tiemann a. Piebst, B. 15, 2033.

**BENZENYL-AMIDO-THIO-CRESOL** v. BENZENYL-AMIDO-THIO-PHENOL.

**BENZENYL-AMIDO-THIO-PHENOL** v. BENZENYL-AMIDO-PHENYL MERCAPTAN.

**BENZENYL-TRI-AMIDO-TOLUENE**

$C_{11}H_9N_3$  i.e.  $Ph.C\langle\begin{smallmatrix} NH \\ N \end{smallmatrix}\rangle C_6H_4Me.NH_2$  [ $\frac{1}{2}$ :1:3]. [183°]. From benzoyl-di-nitro-toluidine, tin, and  $HCl$  (Kelbe, B. 8, 877). Needles, insol. water.— $B'HCl$ .— $B'H_2SO_4$ , aq.

**BENZENYL-TRI-AMIDO-TOLUENE**

$Ph.C\langle\begin{smallmatrix} NH \\ N \end{smallmatrix}\rangle C_6H_4Me.NH_2$  [ $\frac{1}{2}$ :1:3]. **Benzoyl derivative**  $C_{21}H_{17}N_3O_3$  aq. [196°–218°]. From di-benzoyl-nitro- $m$ -tolylene-diamine, tin, and  $HCl$  (Ruhmann, B. 14, 2656). Needles (from alcohol).

**BENZENYL-AMIDO-TOLYL MERCAPTAN**

$C_{11}H_9NS$  i.e.  $C_6H_5\langle\begin{smallmatrix} N \\ S \end{smallmatrix}\rangle C_6H_4$  [125°].

Prepared by heating amido-tolyl mercaptan  $C_6H_5Me(SH)NH_2$  [1:3:4] with benzoyl chloride. Slender needles.— $B'HCl$ : tables, decomposed by water.—( $B'HCl$ ),  $PtCl_4$ , aq (Hess, B. 14, 493).

**BENZENYL-AMIDOKIM** v. BENZ-AMIDOXIM.

**DI-BENZENYL TRI-AMINE**

$C_{14}H_{11}N_3$  i.e.  $\{Ph.C(NH)_2\}_3NH$ . [109°]. Formed by boiling benzamidine with  $Ac_2O$ . Needles (Pinner a. Klein, B. 11, 8).

**BENZENYL-AMYL-PHENYLENE-DI-AMINE** v. BENZENYL-PHENYLENE-DIAMINE.

**BENZENYL-BROMO-PHENYLENE-DI-AMINE**

$C_{11}H_7BrN_2$  i.e.  $C_6H_5C\langle\begin{smallmatrix} NH \\ N \end{smallmatrix}\rangle C_6H_4Br$  [ $\frac{1}{2}$ :2:4]. [200°]. From benzoyl-bromo-nitro-aniline by reduction (Hübner, B. 8, 564; 10, 1710). Small needles, insol. water.— $B'HCl$ .— $B'HNO_2$ .— $B'H_2SO_4$ .

**BENZENYL-DICINNAMYLENE-DI-AMINE**

$C_{23}H_{17}N_2$  i.e.  $PhCH:CH.CH-NH\langle\begin{smallmatrix} CH \\ CH \end{smallmatrix}\rangle CPh$  [207°].

**Phenyl-di-styryl-glyoxaline di-hydrate.** Formed by heating di-benzoyl-dicinnamylene-diamine with potash in a sealed tube (Japp a. Wynne, C. J. 49, 470). Faint yellow crystals. Boiled with  $HCl$  it forms a hydrochloride, sol.  $EtHO$ , which yields a platinumchloride ( $C_{23}H_{17}N_2.HCl$ ),  $PtCl_4$ .

**BENZENYL-ETHOXIM-CHLORIDE**

$C_8H_9ClOEt$  (125°) at 45 mm.; (230°) at 760 mm. V.D. (to H) = 9.26 (obs.). Colourless oil. V. sol. alcohol and ether, insol. water. It is very stable towards water, acids, and alkalis. Formed by the action of  $NaNO_2$  and  $HCl$  upon the ethyl ether of benzenyl-amidoxim  $C_6H_5C(NH_2)NOEt$ . By heating with alcoholic  $NH_3$ , the parent substance is reproduced. By heating with sodium ethylate it yields benzenyl-ethoxim-ethyl ether  $C_6H_5C(OEt)NOEt$  (Tiemann a. Krüger, B. 18, 727; 1057).

**BENZENYL-ETHOXIM-ETHYL ETHER**

$C_8H_9C(OEt)NOEt$  a. *Ethyl-benz-hydroxamic-ethyl ether*. (128°) at 40 mm.; (238°) at 760 mm. V.D. (to H) = 9.675 (obs.). Colourless oil. Insol. water. Formed by heating benzenyl-ethoxim-chloride  $C_6H_5C(NOEt)Cl$  with sodium ethylate. By  $HCl$  it is decomposed into benzoic ether and the ethyl-ether of hydroxylamine  $H_2N.OEt$  (Tiemann a. Krüger, B. 18, 742).

**BENZENYL-ETHYL-AMIDINE**  $C_{11}H_{11}N_2$  i.e.  $PhC(NEt)NH_2$ . From benzamidine and  $EtI$  (Pinner a. Klein, B. 11, 7). Oil.—( $B'HCl$ ),  $PtCl_4$ .

**DI-BENZENYL-IMIDO-AMIDE** v. DI-BENZ-ENYL-TRIAMINE.

**BENZENYL-ETHYL-PHENYLENE-DI-AMINE** v. BENZENYL-PHENYLENE-DIAMINE.

**BENZENYL-METHOXIM-CHLORIDE**

$C_8H_9ClOMe$ . (225° uncorr.). V.D. 74–95. Formed by the action of  $HCl$  and  $NaNO_2$  upon the methyl ether of benzenyl-amidoxim  $C_6H_5C(NH_2)NOMe$  (Krüger, B. 17, 1689; 18, 1057). Oily fluid. Very volatile with steam. Sol. alcohol, ether, benzene, and ligroin, insol. water.

**BENZENYL-METHYL-PHENYLENE-DI-AMINE** v. BENZENYL-PHENYLENE-DIAMINE.

# **BENZENYL-NAPHTHYL-AMIDINE** c. **NAPHTHYL-BENZAMIDOXIM.**

## **BENZENYL-NAPHTHYLENE-DIAMINE**

$C_{17}H_{15}N_2$ , i.e.  $PhC \begin{smallmatrix} \text{NH} \\ \text{N} \end{smallmatrix} > C_6H_4$ . [210°]. From benzoyl-nitro-(β)-naphthylamine, tin, and HCl in presence of alcohol (Ebell, A. 208, 324). Yellowish crystals, sl. sol. water, v. sol. alcohol. Salts.—B'HCl.—B'HNO<sub>3</sub>.—B'H<sub>2</sub>SO<sub>4</sub>.—B'C<sub>6</sub>H<sub>5</sub>I: small needles; NaOH aq. or hot water removes the isocanyl iodide.

**BENZENYL-OXAMIDINE** is **BENZENYL-AMIDOXIM** (q. v.).

**BENZENYL-OXIMIDAMIDE** is **BENZENYL-AMIDOXIM** (q. v.).

**BENZENYL-PHENYL-AMIDINE** v. **PHENYL-BENZAMIDINE**.

**BENZENYL-DI-PHENYL-DI-AMINE** v. **DI-PHENYL-BENZ-AMIDINE**.

## **BENZENYL-o-PHENYLENE-DI-AMINE**

$C_{17}H_{15}N_2$ , i.e.  $C_6H_5 \begin{smallmatrix} \text{C} \\ \text{N} \end{smallmatrix} \begin{smallmatrix} \text{NH} \\ \text{N} \end{smallmatrix} > C_6H_4$ . [280°].

*Anhydro-benzoyl-di-amido-benzene*. From benzoyl-nitro-aniline, tin, and HCl (Hübner, A. 208, 302; 210, 328). Plates (from glacial HOAc). M. sol. alcohol, sl. sol. benzene and water.

Salts.—B'HCl.—B'H<sub>2</sub>PtCl<sub>6</sub>.—B'HI aq.—B'HNO<sub>3</sub>.—B'H<sub>2</sub>SO<sub>4</sub>, 11 aq.

Reactions.—1. *Benzoyl chloride* at 200° has no action.—2. Heated with *cyanogen iodide* and benzene, pale yellow crystals of  $Ph.C \begin{smallmatrix} \text{N(CN)} \\ \text{N} \end{smallmatrix} > C_6H_4$  [106°] are formed (Howe, Am. 5, 416).—3. *Methyl iodide* forms  $C_{17}H_{15}MeN_2MeI$  [141°], whence potash forms  $C_{17}H_{15}MeN_2MeOH$  [152°], insol. hot water, sl. sol. cold alcohol. It forms the following crystalline salts:  $C_{17}H_{15}MeN_2MeCl$  aq.—( $C_{17}H_{15}MeN_2MeCl$ )<sub>2</sub>PtCl<sub>6</sub>.— $C_{17}H_{15}MeN_2MeI$ , [280°].  $C_{17}H_{15}MeN_2MeNO_3$ .— $C_{17}H_{15}MeN_2MeSO_4$  11 aq.—4. *Ethyl iodide* forms at 180°  $C_{17}H_{15}EtN_2$ , m. sol. water. It forms soluble crystalline salts, B'HCl and B'H<sub>2</sub>SO<sub>4</sub>.—5. *Ethyl iodide* at 210° forms  $C_{17}H_{15}EtN_2EtI$  [155°] whence hot potash liberates the crystalline ammonium base  $C_{17}H_{15}EtN_2EtOH$  [132°], insol. water and alkalis, sl. sol. cold alcohol, v. e. sol. benzene and ligroin. Its salts are crystalline and not decomposed by NH<sub>3</sub>, Na<sub>2</sub>CO<sub>3</sub>, or cold KOH, but hot potash liberates the base. Salts.— $C_{17}H_{15}EtN_2EtCl$  2 aq.—( $C_{17}H_{15}EtN_2EtCl$ )<sub>2</sub>PtCl<sub>6</sub>.— $C_{17}H_{15}EtN_2EtI$ .— $C_{17}H_{15}EtN_2EtSO_4$  11 aq.—6. *Isocanyl iodide* at 170° gives  $C_{17}H_{15}(C_6H_5)_2N_2$ . Salts.—B'HCl.—B'HI.—B'HNO<sub>3</sub>.—B'H<sub>2</sub>SO<sub>4</sub> 2 aq.—7. *Isocanyl iodide* at 165° for 24 hours gives  $C_{17}H_{15}(C_6H_5)_2N_2(C_6H_5)_2I$  [112°]. The free ammonium base,  $C_{17}H_{15}(C_6H_5)_2N_2(C_6H_5)_2OH$  [81° and 92°] crystallises from alcohol, and is insol. water. Salts.—B'C<sub>6</sub>H<sub>5</sub>Cl aq. (and 3 aq.).—B'C<sub>6</sub>H<sub>5</sub>I<sub>2</sub>PtCl<sub>6</sub>.—B'C<sub>6</sub>H<sub>5</sub>NO<sub>3</sub>·HNO<sub>3</sub>. [302°].—B'C<sub>6</sub>H<sub>5</sub>I<sub>2</sub>.—8. Conc. *nitric acid* forms a nitro-compound,  $C_{17}H_{15}(NO_2)_2N_2$  [196°].—9. H<sub>2</sub>SO<sub>4</sub> forms an unstable sulphonic acid.

## **BENZENYL-PHENYLENE-DIAMINE-p-CARBOXYLIC ACID** $C_{17}H_{13} \begin{smallmatrix} \text{NH} \\ \text{N} \end{smallmatrix} > C_6H_4.CO_2H$

Slender needles (containing 11 aq.). Almost insol. in cold, v. sol. in hot, water. Prepared by the oxidation of toluenyl-phenylene-diamine

$C_6H_5 \begin{smallmatrix} \text{NH} \\ \text{N} \end{smallmatrix} > C_6H_4.CO_2H$ , with K<sub>2</sub>C<sub>2</sub>O<sub>4</sub> and H<sub>2</sub>SO<sub>4</sub>.

Salts.—BaA', 6 aq.; small needles, sl. sol. water.—CaA', 6 aq.; slender needles.—KA' 7 aq.; long needles, v. e. sol. water.—AgA': white gelatinous pp.

Reaction.—The silver salt on distillation gives a ketone '*Anhydro-tolyl-ketamine*'  $C_{17}H_{13}N_2O$  or

$C_6H_5 \begin{smallmatrix} \text{NH} \\ \text{N} \end{smallmatrix} > C_6H_4.CO_2C_6H_5 \begin{smallmatrix} \text{NH} \\ \text{N} \end{smallmatrix} > C_6H_5$

[277°] which forms salts B'2HCl and B'H<sub>2</sub>PtCl<sub>6</sub>. *Ethyl ether* EtA'.—[213°]; colourless needles (Stoddard, B. 11, 293; Brückner, A. 205, 113; Hübner, A. 210, 337).

**BENZENYL-PHENYL-THIURAMIDOXIM**  $C_6H_5.C(NHCS.NHC_6H_5)_2NOH$ . [163°]. Formed by the combination of phenyl-thio-carbimide with benz-amidoxim (Krüger, B. 18, 1060). Plates. V. e. sol. alcohol, ether and benzene.

**BENZENYL-PHENYL-URAMIDOXIM**  $C_6H_5.C(NH.CO.NHC_6H_5)_2NOH$ . [115°]. Formed by the combination of phenyl cyanate with benz-amidoxim (Krüger, B. 18, 1059). White plates. V. e. sol. alcohol, ether and benzene, insol. cold water.

**BENZENYL-TOLYLENE-DIAMINE**  $C_{17}H_{15}N_2$ , i.e.  $C_6H_5 \begin{smallmatrix} \text{C} \\ \text{N} \end{smallmatrix} \begin{smallmatrix} \text{NH} \\ \text{N} \end{smallmatrix} > C_6H_4.CH_3$ . [124°].

From benzoyl-nitro-p-toluidine, tin, and HCl (Hübner, A. 208, 316). Also by heating acetophenone with o-tolylene-diamine (Ladenburg a. Rügheimer, B. 12, 951). Crystalline, insol. water, v. sol. hot alcohol; may be distilled.

Salts.—B'HCl: needles; sl. sol. cold water and alcohol.—B'H<sub>2</sub>SO<sub>4</sub>: needles; v. m. sol. cold water.

Reactions.—1. *Methyl iodide* at 210° gives  $C_{17}H_{15}MeN_2MeI$  [106°] whence KOH forms  $C_{17}H_{15}MeN_2MeOH$  [144°], insol. water, of which base the following salts are crystalline, viz.:  $C_{17}H_{15}MeN_2Cl$  2 aq.—( $C_{17}H_{15}MeN_2Cl$ )<sub>2</sub>PtCl<sub>6</sub>.— $C_{17}H_{15}MeN_2I$ .— $C_{17}H_{15}MeN_2SO_4$  11. Nitrous acid produces a nitro-compound  $C_{17}H_{15}(NO_2)MeN_2OH$  [165°] (Hübner, A. 210, 371) which forms a platinochloride, ( $C_{17}H_{15}(NO_2)MeN_2Cl$ )<sub>2</sub>PtCl<sub>6</sub>, and reduces to an amido-compound.—2. *Ethyl iodide* at 300° gives  $C_{17}H_{15}EtN_2I$  [129°] whence  $C_{17}H_{15}EtN_2OH$  [163°] and its salts  $C_{17}H_{15}EtN_2CHCl$ . ( $C_{17}H_{15}EtN_2Cl$ )<sub>2</sub>PtCl<sub>6</sub>.— $C_{17}H_{15}EtN_2I$ .— $C_{17}H_{15}EtN_2SO_4$  11 aq.

**BENZENYL-p-TOLYL-TOLYLENE-DI-AMINE**  $C_{17}H_{13} \begin{smallmatrix} \text{C} \\ \text{N} \end{smallmatrix} > C_6H_4$ . [166°]. Needles or prisms. Formed by reduction of benzoyl-nitro-di-tolyl-amine with tin and HCl.

Salts.—B'HI 2 aq.—B'H<sub>2</sub>SO<sub>4</sub>: prisms (Lellmann, B. 15, 832).

**BENZENYL-XYLENE-DIAMINE**  $C_{17}H_{13}N_2$ , i.e.  $C_6H_5 \begin{smallmatrix} \text{C} \\ \text{N} \end{smallmatrix} > C_6H_4Me$ . [148°].

From benzoyl-nitro-xylidine [186°], tin, and glacial HOAc (Hübner, A. 208, 320). Needles, insol. water. Boiling fuming HNO<sub>3</sub> forms a compound, crystallising in yellow needles [302°].

Salts.—B'HCl.—B'HNO<sub>3</sub>.—B'H<sub>2</sub>SO<sub>4</sub>.—B'H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>.

$\text{O}_2\text{N} \cdot \text{C}_6\text{H}_4 \cdot \text{NH} \cdot \text{C}_6\text{H}_4 \cdot \text{Me}$ . [315°]. From benzoyl-nitro-xylylene (178°). Needles. —  $\text{B}^{\text{H}}\text{Cl}$  aq (Hübner, B. 10, 1711).

**BENZ-ERYTHRENE**  $\text{C}_{12}\text{H}_{16}$ . [307°–308°]. Formed in leading benzene through a red-hot tube (Berthelot, J. 1860, 541; 1867, 599, 605; Schultz, D. 11, 95). Small leaflets. Almost insoluble in alcohol, difficultly soluble in hot acetic acid and in cold benzene.

**BENZ-FURIL**  $\text{C}_{12}\text{H}_8\text{O}_2$ , i.e.  $\text{Ph} \cdot \text{CO} \cdot \text{CO} \cdot \text{C}_6\text{H}_3\text{O}$ . [41°]. From benz-furoin and Fehling's solution at 50° (Fischer, A. 211, 229). Yellow needles. V. sol. alcohol or ether (unlike furil). Volatile. Tetra-bromide  $\text{C}_{12}\text{H}_4\text{O}_2\text{Br}_4$ . [127–128°]. Yellow needles.

**BENZ-FURILIC ACID**  $\text{C}_{12}\text{H}_8\text{O}_3$ , i.e.  $\text{O}_2\text{N} \cdot \text{C}_6\text{H}_4 \cdot \text{CPh}(\text{OH}) \cdot \text{CO}_2\text{H}$ . From benz-furil and aqueous KOH at 60°. Prisms (from a mixture of ether with light petroleum). Turns brown at 108°. V. sol. ether, alcohol, or chloroform; d. sol. light petroleum. Its aqueous solution gradually decomposes. The crystals in conc.  $\text{H}_2\text{SO}_4$  give a blood-red colour, turning brown. The oily residue got on evaporating an ethereal solution of benz-furilic acid gives with conc.  $\text{H}_2\text{SO}_4$  a reddish-violet colour, water then gives a blackish-blue pp., which dissolves in conc.  $\text{H}_2\text{SO}_4$ , giving a blue colour (E. Fischer, A. 211, 231).

**BENZ-FUROIN**  $\text{C}_{12}\text{H}_{10}\text{O}_2$ , i.e. Either  $\text{Ph} \cdot \text{CH}(\text{OH}) \cdot \text{CO} \cdot \text{C}_6\text{H}_3\text{O}$  or  $\text{C}_6\text{H}_4\text{O} \cdot \text{CH}(\text{OH}) \cdot \text{CO} \cdot \text{Ph}$ . [187°–139°]. From furfural (18 g.), benzoic aldehyde (20 g.), alcohol (60 g.), water (80 g.), and KCN (4 g.), by boiling for 20 minutes (E. Fischer, A. 211, 228, B. 13, 1339). Slender prisms (from alcohol). May be distilled. V. sol. hot alcohol, chloroform, or benzene, sl. sol. water or light petroleum. Alcoholic KOH forms a dark-red solution with bluish-green reflex.

**BENZGLYCOCYAMINE**  $\text{C}_{11}\text{H}_{12}\text{N}_2\text{O}_2$ . Formed by boiling the dicyanide of *m*-amido-benzoic acid (v. p. 187) with KOH aq (Griess, B. 1, 191; 3, 708; Z. 4, 725; 6, 728) or by the action of cyanamide on an alcoholic solution of *m*-amido-benzoic acid containing  $\text{NH}_3$  (Griess, B. 7, 575). Thin white four-sided plates (containing aq). Sl. sol. hot water, v. sl. sol. ether, insol.  $\text{NH}_4\text{Aq}$ , sol. aqueous mineral acids. Boiling baryta converts it into *m*-amido-benzoic acid, urea,  $\text{NH}_3$ , and uramido-benzoic acid.

Salts. —  $\text{B}^{\text{H}}\text{Cl}$ . —  $\text{B}^{\text{H}}\text{H} \cdot \text{PtCl}_4$ .

**BENZGLYCOCYAMIDINE**  $\text{C}_8\text{H}_8\text{N}_2\text{O}$ , i.e.  $\text{HN} \cdot \text{C} \begin{smallmatrix} \text{NH} - \text{C}_6\text{H}_4 \\ \text{NH} - \text{CO} \end{smallmatrix}$ . Formed by the prolonged heating of 'ethoxy-cyanamid-benzoyl' (v. p. 155) with alcoholic  $\text{NH}_3$  at 100°; or by the action of cyanamide on *o*-amido-benzoic acid (Griess, B. 1, 191; 2, 415; Z. [2] 5, 574; B. 7, 574; 8, 322; 13, 977). Nacreous laminae, v. sl. sol. water, sl. sol. boiling alcohol. Its nitrate forms narrow laminae, v. sl. sol. alcohol. Platinochloride:  $\text{B}^{\text{H}}\text{H} \cdot \text{PtCl}_4$ .

*m*-Carboxy-phenyl-benz-glycocyamine  $\text{HN} \cdot \text{C}_6\text{H}_4 \cdot \text{CO}$

$\text{CO} \cdot \text{H}_2\text{C} \cdot \text{H} \cdot \text{NH} \cdot \text{C} \begin{smallmatrix} \text{NH} - \text{C}_6\text{H}_4 \\ \text{NH} - \text{CO} \end{smallmatrix}$ . Formed from a mixture of 'dicyanamido-benzoyl'  $\text{HN} \cdot \text{C}_6\text{H}_4 \cdot \text{CO}$

and *m*-amido-benzoic acid by

needles or plates. Insol. neutral solvents. Tolerably strong acid.

Salts. —  $\text{A}^{\text{H}}\text{Ag}$ : white amorphous pp. —  $\text{A}^{\text{H}}\text{Ba}$  10aq (Griess, B. 18, 2420).

'Imido-phenyl-benz-glycocyamine' so  $\text{NH} \cdot \text{C}_6\text{H}_4 \cdot \text{CO}$  balled.  $\text{HN} \cdot \text{C} \begin{smallmatrix} \text{NH} - \text{C}_6\text{H}_4 \\ \text{NH} - \text{C}_6\text{H}_4 \cdot \text{NH} \end{smallmatrix}$  [1.3]. Formed by

heating cyanoarbitimidamidobenzoic acid with *o*-phenylene diamine (Griess, B. 18, 2414). Six-sided tables. Nearly insol. water, alcohol, and ether. It has both acid and basic properties. Salts:  $\text{A}^{\text{H}}\text{Ba}$ . —  $\text{A}^{\text{H}}\text{HCl}$ : white six-sided plates.

**BENZHYDRAMIDE** v. BENZOIC ALDEHYDE.

**BENZHYDRAZOIN** v. TRI-PHENYL-HYDRAZOIN.

**BENZHYDROL** v. DI-PHENYL CARBINOL.

**BENZHYDROLENE**  $\text{C}_{12}\text{H}_{10}$ . [210°]. Got by distilling succinate or benzoate of benzhydrol (Linnemann, A. 133, 1), is identical with tetra-phenyl-ethane (Zagumenny, J. R. 12, 431).

**BENZHYDROXAMIC ACID** v. HYDROXYLAMINE.

**BENZHYDRYL ACETATE** v. Acetyl-BENZ-HYDROL.

**BENZHYDRYLAMINE** v. DI-PHENYL-CARBINYLAMINE.

**BENZHYDRYL-BENZOIC ACID** v. EXO-OXY-BENZYL-BENZOIC ACID.

**BENZHYDRYL CARBOXYLIC ACID** v. EXO-OXY-BENZYL-BENZOIC ACID.

**BENZHYDRYL PHENOL** v. DI-OXY-DI-PHENYL-METHANE.

**BENZHYDRYL-ISO-PHTHALIC ACID** v. OXY-BENZYL-ISO-PHTHALIC ACID.

**BENZHYDRYL-PROPIONIC ACID** v.  $\gamma$ -OXY- $\gamma$ -PHENYL-BUTYRIC ACID.

**BENZHYDRYL-PROPIO-CARBOXYLIC ACID** v. OXY-CARBOXY-PHENYL-PROPIONIC ACID.

**BENZIDINE** and derivatives v. DI-AMIDO-DIPHENYL and derivatives.

**BENZIL**  $\text{C}_{14}\text{H}_{10}\text{O}_2 = \text{C}_6\text{H}_5 \cdot \text{CO} \cdot \text{CO} \cdot \text{C}_6\text{H}_5$ . Di-benzoyl. [95°] (Limpricht a. Schwanert); (346°–348° corr.) (Wittenberg a. V. Meyer).

Formation. — 1. By passing chlorine into melted benzoil:  $\text{C}_6\text{H}_5 \cdot \text{CH}(\text{OH}) \cdot \text{CO} \cdot \text{C}_6\text{H}_5 + \text{Cl}_2 = \text{C}_6\text{H}_5 \cdot \text{CO} \cdot \text{CO} \cdot \text{C}_6\text{H}_5 + 2\text{HCl}$  (Laurent, A. Ch. [2] 50, 402). — 2. By oxidising benzoil with nitric acid (Zinin, A. 34, 188), and in small quantity by the air-oxidation of benzoil dissolved in alcohol:  $\text{Me potash } \text{C}_{14}\text{H}_{10}\text{O}_2 + \text{O} = \text{C}_{14}\text{H}_{10}\text{O}_2 + \text{H}_2\text{O}$  (Limpricht a. Schwanert, B. 4, 335). — 3. Together with stilbene by heating stilbene dibromide with water to 150°:  $3\text{C}_6\text{H}_5 \cdot \text{CHBr} \cdot \text{CHBr} \cdot \text{C}_6\text{H}_5 + 2\text{H}_2\text{O} = \text{C}_6\text{H}_5 \cdot \text{CO} \cdot \text{CO} \cdot \text{C}_6\text{H}_5 + 2\text{C}_6\text{H}_5 \cdot \text{CH} \cdot \text{CH} \cdot \text{C}_6\text{H}_5 + 6\text{HBr}$  (L. a. S., A. 145, 338). — 4. Together with toluene by heating toluene-dibromide with water to 200°:  $2\text{C}_6\text{H}_5 \cdot \text{CBr} \cdot \text{C}_6\text{H}_5 + 2\text{H}_2\text{O} = \text{C}_{14}\text{H}_{10}\text{O}_2 + \text{C}_6\text{H}_5 \cdot \text{CH} \cdot \text{CH} \cdot \text{C}_6\text{H}_5 + 4\text{HBr}$  (L. a. S., B. 4, 380). — 5. From toluene-tetra-chloride by heating it with glacial acetic acid or with conc.  $\text{H}_2\text{SO}_4$  to 165°:  $\text{C}_6\text{H}_5 \cdot \text{CCl}_2 \cdot \text{CCl}_2 \cdot \text{C}_6\text{H}_5 + 2\text{H}_2\text{SO}_4 = \text{C}_{14}\text{H}_{10}\text{O}_2 + 2\text{SO}_3 + 4\text{HCl}$

(Liebermann a. Homeyer, B. 12, 1975). — 6. By heating benzoyl chloride with sodium amalgam:  $2\text{C}_6\text{H}_5 \cdot \text{COCl} + \text{Na}_2 = \text{C}_{14}\text{H}_{10}\text{O}_2 + 2\text{NaCl}$  (Klinges, B. 18, 996).

Preparation. — Benzoil is heated with twice

is mixed with sulphuric acid (S.G. 1.8), until it is completely into a clear oily liquid (Zinn). The mixture is poured into water, and the benzil, which at once solidifies, is purified by recrystallisation from boiling alcohol.

**Properties.**—Crystallises from hot alcohol in transparent yellow needles; from ether, by spontaneous evaporation, in large six-sided prisms. Insol. water, v. sol. hot alcohol and ether. The crystals are optically active, showing sometimes dextro-rotation, sometimes laevo-rotation, but having no hemihedral faces. Inactive in a fused state or in solution (Descloiseaux, C. C. 1870, 418).

**Reactions.**—1. Benzil is readily attacked by reducing agents. Iron filings and acetic acid, or zinc and hydrochloric acid, acting upon the alcoholic solution, convert it into benzoin (Zinn, A. 119, 177). When heated with alcoholic potassium hydroxide at 120° it yields a mixture of deoxybenzoin ( $C_{11}H_9CH_2CO.C_2H_5$ ) and benzoin (Jena, A. 155, 87). Sodium amalgam and water convert it into hydrobenzoin (Zincke & Forst, B. 8, 797). When a solution of benzil in moist ether is exposed in a sealed tube to sunlight the benzil is reduced to benzil-benzoin  $C_{22}H_{18}O_2$  [134°–135°], which separates in rosettes of white or pale yellow crystals on the sides of the tube, whilst the ether is converted into aldehyde. On melting benzil-benzoin, or on attempting to recrystallise it from any of the usual solvents, it breaks up into benzil and benzoin:  $C_{22}H_{18}O_2 = 2C_{11}H_9O_2$  (Klinger, B. 19, 1861). 2. Benzil is very stable towards acids. It may be boiled with fuming hydrochloric acid without undergoing change; conc. sulphuric acid dissolves it, and the addition of water precipitates it unaltered; ordinary strong nitric acid does not attack it. On boiling it with fuming nitric acid, however, it yields a mixture of two dinitro-benzils,  $C_{11}H_7(NO_2)_2O_2$ , which may be separated by crystallisation: octahedral crystals [131°], sl. sol. alcohol; and laminae [147°], less soluble than the foregoing (Zugmenny, J. R. 4, 278). An isodinitrobenzil [205°] has been indirectly prepared by the oxidation of  $\alpha$ - or  $\gamma$ -dinitro-deoxybenzoin; v. sl. sol. alcohol, m. sol. boiling benzene or glacial acetic acid (Golabeff, J. R. 13, 29). A mononitrobenzil,  $C_{11}H_8(NO_2)O_2$ , has also been indirectly obtained by boiling 1 part of deoxy-benzoin with 8 parts of nitric acid (S.G. 1.2), or by adding benzoin to nitric acid (S.G. 1.5) cooled to 0°. Yellow laminae or flat needles; m. sol. alcohol, more readily in ether. Hot alcoholic potash decomposes it into potassium *m*-azobenzonate and potassium *m*-oxybenzoate:

Tin and hydrochloric acid convert it into *amido-deoxybenzoin*,  $C_{11}H_9(NH_2)O$  (Zinn, A. Suppl. 3, 158).—3. When heated with soda-lime, benzil yields benzene and benzophenone,  $CO(C_6H_5)_2$  (Jena, A. 155, 87); distilled over heated litharge it yields benzophenone (Wittenberg & V. Meyer, B. 16, 501).—4. When benzil is heated with an equal weight of caustic potash or caustic soda dissolved in 20 parts of water, the benzil slowly decomposes, forming a benzoate (v. BENZOIC ACID):  $C_{11}H_7.CO.CO.C_2H_5 + KOH = (C_6H_5)_2C(OH).COOK$ . A small quantity of diphenyl-carbinol is formed

at the same time by the decomposition of the benzoic acid (Klinger, B. 19, 1861). **Alcoholic potash** dissolves benzil with a violet colour; on heating, the colour is discharged and the solution contains potassium benzoate. According to Klinger (loc. cit.) aqueous potash gives this colouration only with benzoin, and then only when air is admitted. When benzil is dissolved, without heating, in very dilute alcoholic potash (4 grams KOH to the litre) and allowed to stand, with exclusion of air, for about a fortnight, it is converted into a mixture of two compounds,  $C_{22}H_{18}O_2$  [200°–201°] (Limpriecht & Schwanert's so-called *ethyl-dibenzoate*) and  $C_{22}H_{18}O_2$  [232°]. The alcohol takes part in the formation of these compounds:  $2C_{11}H_9O_2 + C_2H_5O = C_{22}H_{18}O_2 + H_2O$ , and  $3C_{11}H_9O_2 + 2C_2H_5O = C_{22}H_{18}O_2 + 4H_2O$ . These two substances can be separated by recrystallisation from alcohol, in which the compound  $C_{22}H_{18}O_2$  is the more soluble. The compound  $C_{22}H_{18}O_2$  is sl. sol. boiling alcohol, sl. sol. boiling benzene, v. sol. boiling glacial acetic acid; deposited from alcohol in colourless granular crystals with 1 mol. of alcohol of crystallisation which is expelled at 120° but not at 100°; crystallises also with 1 mol. of acetic acid and with benzene of crystallisation. The compound  $C_{22}H_{18}O_2$  is finally purified by dissolving in boiling phenol and precipitating with alcohol; yellow crystalline powder, v. sl. sol. alcohol, m. sol. boiling phenol (Japp & Owens, C. J. 47, 90; cf. also Limpriecht & Schwanert, B. 4, 335). Benzil also reacts with isopropyl alcohol: when it is dissolved in a dilute solution of caustic potash in isopropyl alcohol (2:100) and allowed to stand for some months in a stoppered vessel a compound  $C_{22}H_{20}O_2$  [147°–148°] is formed;  $2C_{11}H_9O_2 + C_3H_7O = C_{22}H_{20}O_2 + O$ , a reduction taking place.  $C_{22}H_{20}O_2$  forms very lustrous crystals of rhombohedral habit, v. sl. sol. boiling alcohol (Japp & Raschen, C. J. 49, 832).—5. Benzil reacts with acetone in presence of caustic potash, yielding the compounds acetone-benzil,  $C_{17}H_{14}O_3$ ; anhydronacetone-benzil,  $C_{17}H_{12}O_3$ ; and anhydronacetone-dibenzil,  $C_{22}H_{16}O_4$  (v. ACETONE-BENZIL, p. 32). With methyl ethyl ketone it yields methyl-anhydronacetone-benzil,  $C_{17}H_{14}O_3$ ; colourless thin prisms [179°]; with diethyl ketone, dimethyl-anhydronacetone-benzil,  $C_{17}H_{14}O_3$ ; rhomboidal plates [150°]; with methyl propyl ketone, ethyl-anhydronacetone-benzil,  $C_{17}H_{14}O_3$ ; needles [156°]; with methyl hexyl ketone, amyl-anhydronacetone-benzil,  $C_{17}H_{14}O_3$ ; silky needles [150–5°]; all sol. alcohol (Japp & Burton, C. J. 51, 431).—6. Benzil reacts with ammoniac, and also with aldehyde and ammonia jointly, to form a number of well-characterised condensation-compounds (v. BENZIL, AMMONIA-DERIVATIVES or). Heated with *avicine* in a sealed tube at 200° it yields *benzil-avicine*,  $C_{21}H_{16}(N.C_6H_5).CO.C_6H_5$  [105°]. Yellow prisms, sol. alcohol (Voigt, J. pr. [2] 84, 23).—7. Warmed with (1,2,4)-tolylene diamine in alcoholic solution it forms *diphenyl toluquinoraline*:

(Hinsberg, B. 17, 322). Benzil also reacts with ethylene-diamine to yield a crystalline compound (Mason, B. 19, 113).—8. Forms compounds

with phenylhydrazine and with phenylhydrazine.

Benzil with free hydroxylamine in aqueous-alcoholic solution at the ordinary temperature yields benzil-mono-oxim  $C_6H_5C(N.OH).CO.C_6H_5$  [180°-181°], even when an excess of hydroxylamine is employed. Small square white leaflets, v. sol. alcohol and ether, sl. sol. water (Wittenberg a. V. Meyer, *B.* 16, 503). Boiled with hydroxylamine hydrochloride in methyl alcohol, with the addition of one drop of hydrochloric acid, a diazom, ( $\alpha$ )-diphenyl-glyoxim  $C_6H_5C(N.OH).C(N.OH).C_6H_5$  [237°] separates. Forms lustrous white laminae, sl. sol. methyl alcohol, alcohol, and ether. Dissolves in conc. caustic soda and is reprecipitated by acids. Sol. with difficulty in ammonia, the solution giving with silver nitrate a yellow pp. (Goldschmidt a. V. Meyer, *B.* 16, 1617). If benzil, hydroxylamine hydrochloride, and alcohol, acidulated with hydrochloric acid, are heated in a sealed tube for several hours at 170°, an isomeric ( $\beta$ )-diphenyl-glyoxim [206°] is formed. White needles, v. sol. boiling alcohol, sl. sol. ether and boiling water. Sol. caustic soda and ammonia. The ( $\alpha$ )-compound can be converted into the ( $\beta$ )-compound by heating it with alcohol in a sealed tube at 180°. The nature of this isomerism is not understood; but analogous cases of isomerism have been observed in the benzil and benzoin groups - thus benzil and isobenzil, hydrobenzoin and isohydrobenzoin (Goldschmidt, *B.* 16, 2177). By heating benzil with phenylhydrazine on the water-bath, benzil-di-phenylhydrazide,  $C_6H_5C(N.H.C_6H_5).C(N.H.C_6H_5).C_6H_5$  [225°], separates. Faintly yellow needles; v. sol. hot chloroform and benzene, sl. sol. alcohol and ether. Gives a dark-violet colouration with conc. sulphuric acid. Does not regenerate phenylhydrazine when heated with strong hydrochloric acid (Pickel, *A.* 232, 230). When benzil in alcoholic solution is mixed with an excess of nearly anhydrous hydrocyanic acid and allowed to stand, large, colourless, tabular, rhombic crystals of benzil dihydrocyanide  $C_6H_5C(OH).CN$  are deposited (Zinin, *A.* 34,

189). The same compound is formed when an ethereal solution of benzil is mixed with powdered potassium cyanide and conc. hydrochloric acid is added drop by drop, cooling during the operation. Melts at 132°, with decomposition into benzil and hydrocyanic acid. Insol. water and benzene, v. sol. ether and light petroleum. When dissolved in alcohol it is decomposed, even in the cold, into benzil and hydrocyanic acid (Jacoby, *B.* 19, 1519). When finely powdered benzil dihydrocyanide is mixed with a large excess of a concentrated solution of HBr in glacial acetic acid and left for some weeks, a solution is obtained which by spontaneous evaporation deposits lustrous crystals of di-phenyl-tartramide  $C_6H_5C(OH).CONH_2.HBr$

midide hydrobromide

[185°] and these, when decomposed by ammonia, yield the free di-phenyl-tartramide. V. sol. alcohol, v. sl. sol. ether (Burton, *B.* 16, 2232). Pure benzil dihydrocyanide is not hydrolysed by conc. hydrochloric acid, but when an alcoholic solution of benzil, to which an excess of

anhydrous hydrocyanic acid has been added, is saturated with gaseous HCl and allowed to stand for some weeks, an acid,  $C_6H_5C.N.O$  (colourless prisms, sol. boiling water, melting at 196°), and a compound,  $C_6H_5C.N_2O$  [196°-197°], are formed. The compound  $C_6H_5C.N_2O$  forms lustrous pale yellow laminae or flat needles, sl. sol. boiling water and benzene, v. sol. boiling alcohol. It is feebly basic and forms with hydrochloric acid a colourless salt which is stable only in presence of excess of acid (Japp a. Miller, *C. J.* 51, 29). When benzil is heated with absolute alcohol and hydrocyanic acid at 200° for four hours, it is decomposed into benzoic aldehyde and ethylic benzoate:  $C_6H_5.CO.CO.C_2H_5 + C_2H_5.OH = C_6H_5.CHO + C_2H_5.CO_2.C_2H_5$ , the hydrocyanic acid apparently undergoing no change. Benzoic acid is also formed (Michael a. Palmer, *Ann.* 7, 191). Benzil and alcohol may also be made to react to form benzoic aldehyde and ethylic benzoate by triturating benzil and potassium cyanide with alcohol; but in this case a portion of the benzaldehyde is further changed into benzoin by the action of the potassium cyanide. By neutralising with sodium carbonate the small quantity of benzoic acid which is also formed in this reaction, and which would otherwise decompose the potassium cyanide, 1 part of the cyanide may be made to induce the foregoing change in 50 parts of benzil (Jourdan, *B.* 16, 658). -10. Benzil unites with nitrides in presence of conc. sulphuric acid, taking up the elements of water. Thus when powdered benzil (1 mol.) is suspended in conc. sulphuric acid, and propionitrile (2 mols.) is gradually added, cooling during the process, a compound  $C_{10}H_{11}N_3O_4$  [197°] is formed:  $C_6H_5C.O_2 + 2C_2H_5.N + H_2O = C_{10}H_{11}N_3O_4$ . Lustrous, colourless needles; v. sol. hot alcohol. Boiling with dilute sulphuric acid decomposes it into benzil, propionic acid, and ammonia. - With benzonitrile and sulphuric acid benzil yields a mixture of two compounds which can be readily separated by means of their very different solubilities in hot alcohol:  $C_{10}H_{11}N_3O_4$  [168°], analogous to the propionitrile derivative, v. sol. boiling alcohol, crystallises from alcohol in efflorescent oblique prisms of the formula  $(C_{10}H_{11}N_3O_4).EtOH$ ; and a compound  $C_{10}H_{11}NO_4$  [225°], almost insol. alcohol, v. sol. boiling phenol, sl. sol. boiling benzene, which crystallises from benzene in microscopic, flat rectangular prisms:  $2C_6H_5C.O_2 + C_6H_5.N + H_2O = C_{10}H_{11}NO_4 + C_6H_5.CO_2H$  (Japp a. Tresidder, *B.* 16, 2652). -11. Heated with somewhat more than the equivalent quantity of phosphorus pentachloride, benzil yields dichlorodibenzoin (chlorobenzil)  $C_6H_5CCl.CO.C_6H_5$  [71°]. Short, thick rhombic prisms, ipsol. water, v. sol. ether, not so readily in alcohol. When heated with alcohol or water to 180° it yields benzil and hydrochloric acid. Zinc and hydrochloric acid, acting on an alcoholic solution, convert the compound into deoxybenzoin; acetic acid and zinc-dust reduce it first to deoxybenzoin, and finally to stilbene.  $PCl_5$  at 200° replaces the remaining oxygen atom by  $Cl_2$ , yielding toluene tetrachloride,  $C_6H_5Cl_4$  (Zinin, *A.* 119, 177; *J.* 1890, 614; *A.* 149, 374).

Isobenzil. -1. A substance having the same composition as benzil is obtained by acting with sodium amalgam on a solution of benzoyl

chloride in anhydrous ether (Brigel, *A.* 185, 177). Ordinary benzil is formed at the same time (Klinger, *B.* 18, 995). Isobenzil forms colourless tabular monoclinic crystals, also lustrous laminae or needles ( $145^{\circ}$ – $150^{\circ}$ ), sol. alcohol, ether and CS<sub>2</sub>. It is probably a polymeride of benzil, for when treated with bromine it yields benzil (1 mol.) and benzoyl bromide (2 mols.):  $C_{14}H_{10}O_4 + Br_2 = C_{14}H_{10}O_4 + 2C_6H_5COBr$ . Heated with alcoholic potash it gives the violet colouration of benzil and is converted into benzilic acid together with a small quantity of benzoic acid (Klinger, *loc. cit.*; also *B.* 19, 1862).—2. By heating benzoic aldehyde with sodium amalgam in an atmosphere of CO<sub>2</sub>, Alexéef (*A.* 129, 317) obtained an oil (314° approx.) to which he assigned the formula  $C_{14}H_{10}O_4$ . S.G. 1.2–1.104 (approx.).

F. R. J.

**BENZIL, AMMONIA-DERIVATIVES OF.** There are four general reactions known, according to which compounds containing the dicarbonyl-group—CO.CO—form condensation-compounds with aldehydes and ammonia jointly. As a knowledge of these reactions is necessary to an understanding not only of the behaviour of benzil with aldehydes and ammonia, but also of that of benzil with ammonia alone, the general equations for these reactions will be introduced at this stage. In the following equations X' stands for the monad hydrocarbon-radicle of the dicarbonyl-compound, and R' for the monad hydrocarbon-radicle of the aldehyde:

Here the dicarbonyl-compound is broken up into two halves, whilst the two aldehyde-groups become directly united. Lastly:

The constitution of the compounds of the last-mentioned type is unknown (Japp a. Streiffeld, *C. J.* 49, 155; Japp a. Hooker, *C. J.* 45, 678; Japp a. Wynne, *C. J.* 49, 464).

It will be shown later on, that in the reactions of benzil with ammonia a part of the benzil is first broken up with formation of benzoic acid and benzoic aldehyde, which latter then takes part, together with benzil and ammonia, in the final reaction. The benzil-ammonia reactions are therefore in reality

Vol. I.

benzil-aldehyde-ammonia reactions, and will be more readily understood if the reactions of the latter class are described first.

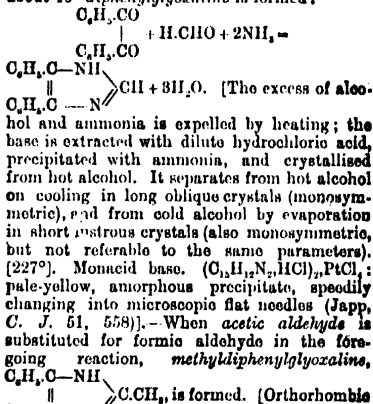

#### REACTIONS OF BENZIL WITH ALDEHYDES AND AMMONIA:—

**Equation I.** (*vide supra*).—Benzil gives no reactions according to this equation so long as free aldehydes are used, but with nascent benzoic aldehyde, produced by the decomposition of a portion of the benzil, it reacts according to this equation, yielding benzilam,  $C_{14}H_{10}NO$  (*vide infra*). In the case of some other dicarbonyl-compounds, however, such as phenanthraquinone (*q. v.*), this reaction occurs with various free aldehydes.

**Equation II.**—Benzil reacts according to this equation with formic aldehyde, acetic aldehyde, isovaleric aldehyde, glyoxal, benzoic aldehyde (free), and *p*-oxybenzoic aldehyde. The compounds formed are derivatives of gly-

Thus when benzil and formic aldehyde are warmed with ammonia in alcoholic solution at about  $40^{\circ}$  diphenylglyoxaline is formed:

[Orthorhombic

crystals [235°],

sol. ether and hot alcohol.

(C}\_{12}H\_{10}N\_2(HCl)\_2.PtCl\_2.2aq: yellow microscopic needles (Japp a. Wynne)].

The base forms a molecular compound with diphenylglyoxaline (J.).

Benzil, isovaleric aldehyde, and ammonia yield isobutyl diphenylglyoxaline,

C}\_{6}H\_5.CO-NH \begin{array}{c} \nearrow C.CH\_2.CH(CH\_3)\_2 \\ \searrow \end{array}

[Needles [223°], sol. hot benzene and alcohol.

(C}\_{12}H\_{12}N\_2(HCl)\_2.PtCl\_2: amorphous yellowish-brown precipitate, or small crystals (J. a. W.).]

Glyoxal, as a dialdehyde, reacts with twice the proportion of benzil and ammonia, forming tetraphenylglyoxaline,

C}\_{6}H\_5.CO-NH \begin{array}{c} \nearrow C \begin{array}{c} \nearrow NH-C.C\_6H\_5 \\ \searrow C.C\_6H\_5 \end{array} \\ \searrow \end{array}

[From hot alcohol in tufts of silky needles of the formula C}\_{12}H\_{10}N\_4.C\_6H\_5O. Melts above  $300^{\circ}$ . Feebly basic (Japp a. Clemmshaw, *C. J.* 51, 558)].

Benzil, benzoic aldehyde, and ammonia yield

*lophine*,  $\text{C}_6\text{H}_5\text{C}(\text{OH})\text{NH}\text{C}(\text{O}_2\text{C}_6\text{H}_5)_2$  (Radziszewski, B. 15, 1498). In a similar manner *p*-oxybenzoic aldehyde gives *p*-oxylophine,  $\text{C}_6\text{H}_4(\text{O})\text{C}(\text{OH})\text{NH}\text{C}(\text{O}_2\text{C}_6\text{H}_4\text{O})_2$ . [Tufts of colourless needles [254°–255°], v. sol. hot alcohol, sol. caustic soda, forming a sodium compound. Heated with acetic anhydride, it forms a monoacetyl-derivative  $\text{C}_{12}\text{H}_{11}(\text{C}_2\text{H}_3\text{O})\text{N}_2\text{O}$  [229°]; needles, with a faint satiny lustre, sol. hot alcohol. Distilled with zinc-dust, *p*-oxylophine is converted into lophine (Japp & Robinson, C. J. 41, 828)].

**Equation III.**—Illustrations of this equation are to be found in the reactions of *salicylic aldehyde* and *furfuraldehyde* (pyromucic aldehyde) with benzil and ammonia. *Cinnamic aldehyde* also reacts according to this equation; but in this case another reaction, according to Equation IV., occurs simultaneously.

Thus when equal weights of *salicylic aldehyde* and benzil are dissolved in warm alcohol and the liquid is saturated with gaseous ammonia, the condensation compound *dibenzoyl-dioxystilbene-diamine* separates as a crystalline powder:

[It is purified by dissolving it in boiling phenol and precipitating with alcohol. Microscopic plates, melting with decomposition above 300°, insol. in the ordinary organic solvents, sol. boiling phenol, sol. caustic soda, forming a sodium compound. By fusion with caustic soda it yields sodium benzoate and sodium salicylate. Heated with dilute hydrochloric acid at 210° it is hydrolysed into benzoic acid and *dioxystilbene-diamine*,  $\text{C}_6\text{H}_4(\text{OH})\text{CH}_2\text{NH}_2$ ;

*diamine*  $\text{C}_6\text{H}_4(\text{OH})\text{CH}_2\text{NH}_2$ ; small lustrous laminae [180–5°], v. sol. hot benzene; di-acid base: the Pt salt,  $\text{C}_{12}\text{H}_{11}\text{N}_2\text{O}_2 \cdot 2\text{HCl} \cdot \text{PtCl}_4 \cdot 4\text{aq}$  forms thick, orange-coloured, rhomboidal plates with bevelled edges, anhydrous at 180°. This base is, however, more readily obtained from its acetyl-derivative (*infra*). When the condensation-compound is boiled with acetic anhydride until it dissolves, *dibenzoyl-dioxystilbene-diamine*,  $\text{C}_6\text{H}_4(\text{O.C}_2\text{H}_5)_2\text{CH.NH}(\text{C}_2\text{H}_5\text{O})$  is

*diamine*  $\text{C}_6\text{H}_4(\text{O.C}_2\text{H}_5)_2\text{CH.NH}(\text{C}_2\text{H}_5\text{O})$  is termed (rhomboidal laminae [225°–227°], sol. acetic acid); and by boiling this compound for eight hours with acetic anhydride the benzoyl-groups are replaced by acetyl-groups yielding *diacetyl-dioxystilbene-diamine*,  $\text{C}_6\text{H}_4(\text{O.C}_2\text{H}_5)_2\text{CH.NH}(\text{C}_2\text{H}_5\text{O})$  (prisms [218°–219°] sol. glacial acetic acid and alcohol, deposited from latter solvent with 1 mol. of alcohol of crystallisation). This compound is tetra-acetyl derivative of the above-mentioned *base*. By the action of caustic alkali or conc.

ammonia, and the benzoyl-groups and the four acetyl-groups may be removed in successive pairs, yielding first *diacetyl-dioxystilbene-diamine*,  $\text{C}_6\text{H}_4(\text{OH})\text{CH.NH}(\text{C}_2\text{H}_5\text{O})$  (crystalline powder melting above 300°, sol. hot phenol, sol. caustic alkalis), and finally *dioxystilbene diamine*. The latter base is most conveniently prepared by heating the tetra-acetyl compound with conc. hydrochloric acid at 120°. By heating the condensation-compound with benzoic anhydride a dibenzoyl derivative, corresponding with the diacetyl derivative is obtained; it is a tetra-benzoyl derivative  $\text{C}_6\text{H}_4(\text{O.C}_6\text{H}_5)_2\text{CH.NH}(\text{C}_6\text{H}_5\text{O})$  of the base, thus:

$\text{C}_6\text{H}_4(\text{O.C}_6\text{H}_5)_2\text{CH.NH}(\text{C}_6\text{H}_5\text{O})$  Microscopic plates [246°–248°], sol. acetic acid; sol. dilute caustic potash on long boiling, regenerating the condensation-compound. These various acetyl and benzoyl derivatives may also be synthesised from *dioxystilbene-diamine* by treatment with acetic anhydride and benzoic anhydride. The dibenzoyl derivative thus prepared is identical with the original condensation-compound (Japp & Hooker)].

Benzil, *furfuraldehyde*, and ammonia also react according to Equation III.:  $\text{C}_{10}\text{H}_6\text{O}_2 + 2\text{C}_5\text{H}_4\text{O}_2 + 2\text{NH}_3 = \text{C}_{10}\text{H}_6\text{N}_2\text{O}_2 + 2\text{H}_2\text{O}$ , forming, however, two isomeric compounds of the formula  $\text{C}_{10}\text{H}_6\text{N}_2\text{O}_2$ . One of these is an analogue of the salicylic aldehyde compound; it is separated by means of its insolubility in alcohol, and purified by dissolving in boiling phenol and precipitating with alcohol. Crystalline powder, v. sol. hot phenol, sl. sol. glacial acetic acid. The isomeric compound crystallises from alcohol in tufts of silky needles [246°] (J. & H.).

When *cinnamic aldehyde*, benzil, and ammonia are allowed to react in alcoholic solution, a mixture of two compounds is obtained. Boiling alcohol extracts one of these, and the remaining compound, which is insoluble in alcohol, is purified by dissolving in hot phenol and precipitating with alcohol. The compound soluble in alcohol is *cinnimabenzil*,  $\text{C}_{18}\text{H}_{14}\text{N}_2\text{O}_2$  (*infra*). The compound insoluble in alcohol is *dibenzoyl-dicinnamylene-diamine* and is formed according to Equation III.:

$\text{C}_6\text{H}_5\text{CH}:\text{CH}.\text{CH}.\text{CH.NH.CO.C}_6\text{H}_5$  Crystalline powder, consisting of short microscopic prisms [264°], insol. in the ordinary organic menstrua, sol. hot phenol. When heated with a solution of potash in methyl alcohol at 160°, it parts with the elements of benzoic acid and is converted into *benzenyl-dicinnamylene-diamine*,  $\text{C}_6\text{H}_5\text{CH}:\text{CH}.\text{CH}=\text{N} \cdot \text{C}_6\text{H}_5$ . Silky needles, [223°], sol. benzene and alcohol. Monacid base: Pt salt,  $(\text{C}_{18}\text{H}_{14}\text{N}_2\text{HCl})_n \cdot \text{PtCl}_4 \cdot 2\text{aq}$ , forms silky needles.

**Equation IV.**—The above-mentioned solution product of the reaction of *cinnamic aldehyde*

with benzil and ammonia — *unfractionated*,  $C_{14}H_{11}NO_2$  is formed according to Equation IV:

$C_6H_5N_2O_2 + KOH = C_6H_5N_2O_2 + C_6H_5COOK$ . Crystalline powder (283°), sol. hot phenol, precipitated by alcohol. By boiling cinnimabenzil with dilute sulphuric acid it is hydrolysed, yielding benzilimide (*intra*), cinnamic aldehyde, benzoic acid, and ammonia:  $C_{14}H_{11}N_2O_2 + 2H_2O = C_6H_5NO_2 + C_6H_5O + C_6H_5O + NH_3$  (Japp and Wynne).

REACTIONS OF BENZIL WITH AMMONIA ALONE. — Laurent, *Revue Scient.* 10, 122; 19, 440; Zinin, *A.* 34, 190; Zincke, *B.* 16, 890; Japp, *B.* 16, 2636; Henius, *A.* 228, 339; Japp a. Wynne, *C.* 49, 473.

By heating benzil with alcoholic ammonia the following compounds are obtained: *imabenzil*,  $C_{14}H_{11}N_2O_2$ ; *benzilimide*,  $C_{14}H_{11}NO_2$ ; *benzilam*,  $C_{14}H_{11}NO$ ; and *lophine*,  $C_{14}H_{11}N_2$ . At the same time benzoic acid, ethylic benzoate, and benzamide are formed. This reaction was first studied by Laurent, who prepared the first three of the above-mentioned compounds, ascribing to them, however, incorrect formulæ.

Benzil is dissolved in alcohol so that the solution is saturated at 40°; gaseous ammonia is passed into the warm liquid to saturation, and the whole is allowed to stand for 24 hours. Prismatic crystals of *imabenzil* are deposited, whilst benzilimide, benzilam, and the other compounds above enumerated remain in solution. If slender acicular crystals of benzilimide should separate they may be removed by warming with alcohol, in which *imabenzil* is soluble only with difficulty. The formation of *imabenzil* may be expressed by the equation:  $3C_{14}H_{11}O_2 + 2NH_3 = C_{14}H_{11}N_2O_2 + C_6H_5COOH + H_2O$ . *Imabenzil* forms small lustrous orthorhombic prisms (194°), al. sol. hot alcohol, decomposing on long boiling, and yielding among other products benzilimide; the best solvent is hot methyl alcohol. Boiled with dilute sulphuric acid (1 vol. acid: 2 vols. water) it is converted into benzilimide, benzil, and ammonia:

$C_{14}H_{11}N_2O_2 + H_2O = C_6H_5NO_2 + C_6H_5O + NH_3$ ; whilst cold conc. sulphuric acid dissolves it, converting it into benzilam, benzaldehyde, benzoic acid, and ammonia:

$C_{14}H_{11}NO + C_6H_5O + C_6H_5O + NH_3$  (Japp a. Wynne). The formation of benzilam in this reaction was first observed by Laurent. Boiling with alcoholic *potash* converts *imabenzil* into benzilimide (Laurent). *Acetic acid* and *acetic anhydride* act like dilute sulphuric acid, decomposing it on boiling with formation of benzilimide and benzil (Henius). Heated for some time to 140° it decomposes and melts, forming benzilimide, benzilam, and lophine, whilst an odour of benzoic aldehyde is perceptible (H.).

The alcoholic ammoniacal method, from the preparation of *imabenzil* yields, when concentrated, a mixture of *benzilimide* and *benzilam*. A similar mixture is obtained by heating benzil with alcoholic ammonia for some hours at 100°, the *imabenzil* which is first formed being converted into benzilimide and benzilam; at 130° *lophine* is also formed (Henius). The formation of lophine occurs according to the equation  $2C_{14}H_{11}O_2 + 2NH_3 =$

$C_{14}H_{11}N_2 + C_6H_5COOH + 2H_2O$ . Benzilimide and benzilam are best separated by boiling the mixture with light petroleum, which extracts the whole of the benzilam, depositing it on cooling, in rosettes of prisms, and hardly dissolves the benzilimide, which may be purified by crystallisation from hot alcohol. *Benzilimide* is formed from benzil and ammonia according to the equation —

$2C_{14}H_{11}O_2 + NH_3 = C_{14}H_{11}NO_2 + C_6H_5COOH$ . Tufts of silky needles (137°–139°) (H.), sol. hot alcohol. Concentrated sulphuric acid dissolves it in the cold, abstracting the elements of water, and converting it into benzilam ( $L.$ ),  $C_{14}H_{11}NO_2 - H_2O = C_{14}H_{11}NO$ . Heating with *acetic anhydride* produces the same effect (H.). *Chromic mixture* oxidises it to benzoic acid (H.). Benzilimide may also be prepared from *imabenzil* by Laurent's method of boiling it with alcoholic potash.

*Benzilam* ( $C_{14}H_{11}NO$ ) may be obtained as above, along with benzilimide, and separated from it as already described, or it may be obtained either from *imabenzil* or from benzilimide, by the action of cold conc. sulphuric acid. The solution of *imabenzil* in the cold acid is poured into water, when benzilam separates and may be purified by recrystallisation from alcohol. Most readily obtained by heating benzil with fused ammonium acetate in a flask over a flame until the ammonium salt is volatilised (Japp a. Wilson, *C.* 49, 829, footnote); but as some lophine is formed at the same time, the benzilam must be extracted by means of hot light petroleum, in which the lophine is practically insoluble. The formation of benzilam from benzil and ammonia may be expressed thus:

$2C_{14}H_{11}O_2 + NH_3 = C_{14}H_{11}NO + C_6H_5COOH + H_2O$ . Well-developed rhombic prisms (from a mixture of ether and alcohol by spontaneous evaporation (H.)) colourless when pure; thin lustrous laminae, sometimes iridescent, (from hot alcohol); rosettes of prisms (from hot light petroleum). [113°–114°]. Distils at a high temperature without decomposition (L.). V.D. (air = 1) 10.23; calculated 10.28 (J.). With nitric acid it yields a mono-nitro-derivative (needles [178°–182°] from benzene) and a dinitro-derivative (H.). *Chromic mixture* oxidises it to benzoic acid (H.).

The above reactions of benzil with ammonia may be explained as follows. In the first place a portion of the benzil is broken up according to the following equations:

These three compounds—benzoic acid, ethylic benzoate, and benzamide—are always formed in the reaction of benzil with alcoholic ammonia. (The benzamide may also be regarded as having been formed in a secondary reaction, from ethylic benzoate and ammonia.) The benzoic aldehyde, which is the by-product in every case, then reacts, in the nascent state, with benzil and ammonia according to one or other of the following equations:

This reaction of an aldehyde with a dicarbonyl compound and ammonia, in which benzilimide is produced, is not known to occur in the case of free aldehydes.

If the reaction occurs according to Equation I. of the general reactions, benzilam is formed:

These formulæ for benzilimide and benzilam account for the readiness with which the former is converted into the latter by the action of dehydrating agents.

If the reaction occurs according to Equation II., lophine is produced:

Finally, if it occurs according to Equation IV., the product is imabenzil:

But free benzoic aldehyde, with benzil and ammonia, yields only lophine.

The foregoing equations express the formation of the various compounds obtained from benzil with alcoholic ammonia. The reactions in which the complex compounds discovered by Laurent are formed thus really occur in two stages, of which the first consists in the formation of benzoic aldehyde, the second in a benzil-aldehyde-ammonia condensation (Japp, *B. 18*, 2686; Japp & Wynne, *C. J.* 49, 477).

F. R. J.

**BENZILIC ACID**  $\text{C}_6\text{H}_5\text{O}_2 = (\text{C}_6\text{H}_5)_2\text{C(OH).COOH}$ . Diphenylglycollic acid. [150°] (Jena).

**Formation.**—1. By warming benzil with

alcoholic potash:  $\text{C}_6\text{H}_5\text{CO.CO.C}_6\text{H}_5 + \text{KOH} = (\text{C}_6\text{H}_5)_2\text{C(OH).COOK}$  (Lieber, *A. 28*, 26; Zinin *A. 81*, 829).—2. By boiling diphenyl-bromo-acetic acid,  $(\text{C}_6\text{H}_5)_2\text{CBr.COOH}$  (obtained by passing the vapour of bromine over heated diphenyl-acetic acid), with baryta water (Symons & Zincke, *A. 171*, 131).

**Preparation.**—1. Benzil is added to five times its weight of melted potash to which a little water has previously been added. The whole solidifies, owing to the formation of potassium benzilate (E. Fischer, *B. 14*, 326 footnote). The mass is dissolved in water, and the benzoic acid is precipitated by hydrochloric acid and recrystallised from boiling water.—2. It can also be prepared from benzoïn. 15 g. benzoïn, 20 g. KOH and from 250 to 300 c.c. water are heated in a current of air until everything has dissolved. The solution is extracted with ether to remove a small quantity of diphenyl-carbinol which is formed by the decomposition of the benzoïlic acid, and solid caustic potash is added. This causes the separation of nacreous laminae of potassium benzilate, which are removed by filtration, washed with a solution of caustic potash, and finally decomposed with sulphuric acid (Klinger, *B. 19*, 1868).

**Properties.**—Small white monoclinic needles with a satiny lustre. Heated above its melting-point it turns red. Conc.  $\text{H}_2\text{SO}_4$  colours it deep red; the colour disappears on the addition of water. V. sol. alcohol, ether, and boiling water; sl. sol. cold water. Bitter taste.

**Reactions.**—1. Heated for several hours to 180° it yields a deep-red liquid, and, on cooling, solidifies to an amorphous mass, from which, by treatment with alcohol, *dibenzilic acid*  $\text{C}_{12}\text{H}_{10}\text{O}_2$  (196°), benzophenone, and other products can be isolated (Jena).—2. Chronic mixture oxidises it to benzophenone:

Benzophenone is also produced when silver benzilate is heated, either alone or with water (J.).—3. Heated with *hydriodic acid* (127°) to 150° it is converted into diphenyl-acetic acid:

Zinc and hydrochloric acid, and sodium amalgam, are without action (J.).—4. Barium benzilate, distilled with  $\frac{1}{10}$ th of its weight of soda-lime, yields diphenyl-carbinol:

$(\text{C}_6\text{H}_5)_2\text{C(OH).COOH} = (\text{C}_6\text{H}_5)_2\text{CH.OH} + \text{CO}_2$  (J.).—5. Treated with  $\text{POCl}_3$  it yields benzil chloride,  $\text{C}_{12}\text{H}_{10}\text{O}_2\text{Cl}_2$ , a heavy, colourless liquid (270°), which in contact with moist air is rapidly decomposed into benzilic and hydrochloric acids (Cahours, *A. 70*, 46).

**Salts.**—Benzilic acid is monobasic.  $\text{C}_{12}\text{H}_{10}\text{O}_2\text{K}$ : v. sol. crystalline salt (Zinin).— $(\text{C}_{12}\text{H}_{10}\text{O}_2)_2\text{Ba}$ : v. sol. crystalline crystals with a fatty lustre (J.); separates from alcohol in anhydrous needles (Symons & Zincke).— $(\text{C}_{12}\text{H}_{10}\text{O}_2)_2\text{Pb}$ : pulverulent precipitate, obtained by adding lead acetate to an aqueous solution of benzoic acid; fuses on heating to a red liquid (Zinin).— $\text{C}_{12}\text{H}_{10}\text{O}_2\text{Ag}$ : easily decomposable precipitate (J.).

*Ethylic benzilate*,  $\text{C}_{12}\text{H}_{14}\text{O}_2$ ,  $\text{C}_6\text{H}_5$ . Separates as an oil when a solution of benzoic acid in ethyl alcohol is saturated with gaseous  $\text{HCl}$  and

## BENZOIC ACID.

then diluted with water. Not volatile without decomposition (2.).

**Ethyl-benzilic acid**,  $C_{11}H_{12}O_2$ , isomeric with the foregoing, is a resinous substance obtained by heating benzoin in alcoholic solution with sodium ethoxide at  $150^\circ$ . Scarcely soluble in potash and ammonia, save in presence of alcohol (Jena, A. Limpriicht, A. 165, 96).

**Dibenzilic acid**,  $C_{14}H_{12}O_4$ , ( $196^\circ$ ), obtained by heating benzilic acid to  $180^\circ$  (v. supra), crystallises from alcohol in minute needles. It is an anhydride, and, by heating with water at  $180^\circ$ , is converted into benzilic acid (Jena, B. 2, 385).

**BENZO-ANILINE** v. AMIDO-BENZOPHENONE.

**BENZO-TRI-CHLORIDE**  $C_6H_2Cl_3$ , i.e.  $C_6H_2Cl_3$ . Mol. w. 196.5. ( $214^\circ$ ). S.G. 1.38.

**Formation**.—1. From benzoyl chloride and PCl, (Wöhler & Liebig, A. 3, 265; Schischkoff & Rosing, C.R. 46, 367; Limpriicht, A. 134, 55; 135, 80; Bl. 1866, ii, 468).—2. From benzylidene chloride by chlorination (Cahours, C. R. 56, 703).—3. By chlorination of toluene (Naquet, C. R. 55, 407; 56, 482).

**Preparation**.—By passing chlorine (3 mols.) into cold toluene (1 mol.) exposed to direct sunshine (Schramm, B. 18, 608) or into boiling toluene.

**Properties**.—Pungent liquid, insol. water, which slowly converts it into benzoic acid (the change is rapid at  $140^\circ$ ). Alcohol at  $130^\circ$  forms benzoic ether.

**Reactions**.—1. Sodium has no action.—2. Ag<sub>2</sub>O forms benzoic anhydride.—3. Aqueous ammonia at  $140^\circ$  gives benzoic acid, benzamide, and benzonitrile, reacting thus:  $C_6H_5CCl_2 + 4NH_3 = 8NH_4Cl + C_6H_5CN$ .—4. Aniline forms di-phenylbenzamidine,  $C_{12}H_{11}C(NC_6H_5)_2.NHC_6H_5$ .—5. Reacts with aromatic bases thus:  $C_6H_5CCl_2 + 2C_6H_5NXY = C_6H_5CCl(C_6H_5NXY)_2 + 2HCl$ .

$C_6H_5O < \begin{matrix} C_6H_5NXY \\ C_6H_5NXY \end{matrix} + 2HCl$ ; whence KOH

forms the carbinol  $C_6H_5C(OH)(C_6H_5NXY)_2$ . The reaction requires presence of a metallic chloride or other condensing agent; it takes place most easily with tertiary bases, least readily with primary bases. The products are dyes, the primary bases giving violet, the secondary and tertiary green, colours.—6. It acts similarly on phenols.  $C_6H_5CCl_2 + 2C_6H_5OH = 2HCl + C_6H_5CCl(C_6H_5OH)_2$ . The products are converted by treatment with water into carbinols  $C_6H_5C(OH)(C_6H_5OH)_2$ , the alkaline salts of which are colouring matters (Doebner, A. 217, 226).—7. Converted by heating with dry oxalic acid, first into Ph.CO.Cl, then into  $(Ph.CO)_2O$ .

(Anschütz, A. 236, 30).—8. Copper produces, on heating,  $C_6H_5.CCl_2.CCl_2.C_6H_5$  (Onufrowicz, B. 17, 833).

**BENZO-CUMIDE** v. PHENYL AMIDO-CUMYL-KETONE.

**BENZO-FURILIC ACID** v. BENZOFURILIC ACID.

**ISO-BENZOGLYCOL**  $C_8H_8O_2$ , i.e.  $C_6H_5(OH)_2$  (?), ( $171^\circ$ ). A crystalline substance formed by the electrolysis of a mixture of benzene, alcohol, and dilute  $H_2SO_4$  (Renard, C. R. 91, 176). Sol. water, alcohol, and ether. Reduces Fehling's solution and ammoniacal AgNO<sub>3</sub>.

**Di-acetyl derivative**  $C_{12}H_{10}(OAc)_2$ , ( $121^\circ$ ). ( $300^\circ$ ). Insol. water, sol. alcohol and ether.

**DI-BENZO-HYDROQUINONE** v. DI-PHENYL DI-OXY-PHENYLENE DI-KETONE.

**BENZOIC ACID**  $C_7H_6O_2$ , i.e.  $C_6H_5.CO_2H$ . Mol. w. 122. ( $121.4^\circ$ ) (Schiff). ( $249.2^\circ$  cor.) (Kopp, A. 94, 303). S.G. 1.20 (Mendeleeff); 1.337 (Rüdorff, B. 12, 250); 1.292 (Schroder, B. 12, 562). S.  $-156$  at  $0^\circ$  (Ost, J. pr. [2] 17, 232);  $-172$  at  $0^\circ$ ;  $-207$  at  $10^\circ$ ;  $-425$  at  $31^\circ$ ;  $-178$  at  $75^\circ$  (Bourgoin, J. Ph. [4] 30, 488). S. (ether) 66 at  $15^\circ$ . S. (alcohol) 47 at  $15^\circ$  (Bourgoin, Bl. [2] 29, 245). H.F. 94,533 (Stohmann, J. pr. [2] 36, 2). S.V. 126 (Ramsay). S.V.S. 112.00 (S.). R<sub>20</sub> 54.21 (in a 6 p.c. benzene solution, Kanounnikoff).

**Occurrence**.—In various resins, e.g. gum benzoin, dragon's blood, storax, and balsams of Peru and Tolu (Blaise du Vigénère, *Traité du feu et du sel*, 1608; Liebig & Wöhler, A. 3, 249). In castoreum (Wöhler, A. 67, 360), in the spindle-tree (*Eugonyrus europæus*). In putrid urine (Liebig, A. 60, 168). In cranberries (Loew, J. pr. [2] 19, 312). In the higher boiling phenolic portion of coal-tar oils (Schulze, B. 18, 615).

**Formation**.—1. By oxidation of benzoic aldehyde, benzyl alcohol, toluene, cinnamic acid, &c.—2. In small quantity, by passing a current of dry CO<sub>2</sub> through a nearly boiling mixture of aluminium chloride and benzene (Friedel & Crafts, C. R. 86, 1364).—3. In small quantity, by the action of  $H_2SO_4$  and MnO<sub>2</sub> on benzene, especially when formic acid is added (Carius, A. 148, 51, 59).—4. By distilling calcic phthalate with lime (Depouilly, Bl. [2] 3, 163, 469).—5. By the action of  $H_2SO_4$  and MnO<sub>2</sub> on cascin or gelatin (Guckelberger, A. 64, 80).—6. By fusing potassium benzene sulphonate with sodium formate (V. Meyer, B. 3, 112).—7. From benzonitrile by saponification.—8. By passing CO<sub>2</sub> into sodium in bromo-benzene (Kekulé, A. 137, 129).

**Preparation**.—1. From gum benzoin by sublimation or by extracting with lime-water or acetic acid (Mohr, A. 29, 178; Schoole, *Opusc.* 2, 23; Wöhler, A. 49, 245; Loew, J. pr. 108, 257; Guichard, Bl. [2] 19, 357). Some varieties of gum benzoin contain cinnamic acid, but this acid is absent from the benzoin of Siam or the Palembang benzoin from Sumatra; the latter yields 10 p.c. benzoic acid (Saulfeld, Ar. Ph. [3] 16, 280). Benzoic acid that has been sublimed from gum benzoin leaves a small quantity of oily residue when treated with aqueous Na<sub>2</sub>CO<sub>3</sub>; this oil consists of guaiacol, methyl benzoate, pyrocatechin, acetyl-guaiacol, benzyl benzoate, benzophenone, and benzoyl-guaiacol (Jacobsen, Ar. Ph. [3] 22, 886).—2. From hippuric acid. Urine of horses or

oxen is left for some days to putrefy, when the hippuric acid is split up into glyccoll and benzoic acid; milk of lime is added and the liquid concentrated; excess of lime is added by  $\text{CO}_2$ , and the filtrate added by  $\text{FeCl}_3$ ; the ferric benzoate is decomposed by  $\text{HCl}$ . Benzoic acid prepared in this way crystallises in plates and smells of urine, but by sublimation it may be freed from the smell and then crystallises in needles (Dymond, *Ph.* [3] 14, 463).—3. From benzo-trichloride by decomposing it with water under pressure, with lime or baryta-water, or with  $\text{ZnCl}_2$  and glacial  $\text{HOAc}$  (2 mols.) at  $100^\circ$  (Jacobsen, *B.* 13, 2013).—4. From benzyl chloride by boiling with dilute  $\text{HNO}_3$  (Lunge a. Petri, *B.* 10, 1275; cf. v. Rad, *D. P. J.* 231, 638).

**Properties.**—Needles or pearly plates. When pure it does not melt under water, but slight impurities greatly affect its physical properties; the so-called salicylic acid was impure benzoic acid (Kolbe a. Lautemann, *A.* 115, 187; Kekulé, *A.* 117, 159; Griess, *A.* 117, 34; Reichenbach a. Beilstein, *A.* 132, 309; Kolbe, *J. pr.* [2] 12, 151). Volatile with steam (1 g. passing over with about 2,000 cc. water). It dissolves in conc.  $\text{H}_2\text{SO}_4$  and is reprecip. by water. It is not attacked by boiling dilute  $\text{HNO}_3$  or  $\text{CrO}_3$  (which convert cinnamic acid into benzoic aldehyde); its neutral salts give a buff-coloured pp. with  $\text{FeCl}_3$ .

**Reactions.**—1. Passage of the vapour through a red-hot tube gives  $\text{CO}_2$  and benzene.—2. Distillation with lime produces benzene.—3. Fusion with  $\text{NaOH}$  produces benzene (75 p.c. of the theoretical amount) and a little diphenyl (Barth a. Senhofer, *B.* 12, 1256).—4. Fusion with  $\text{KOH}$  produces chiefly *p*-oxy-benzoic acid, but also *o*- and *m*-oxy-benzoic acids, oxy-iso-phthalic acid, diphenyl *o*-, *m*-, and *p*-carboxylic acids, and a brown amorphous substance (Barth a. Schreder, *M.* 3, 799).—5.  $\text{MnO}_2$  and  $\text{H}_2\text{SO}_4$  form  $\text{CO}_2$ , formic acid, and small quantities of phthalic and terephthalic acids (Carus, *A.* 118, 50; Oudemans, *Z.* [2] 5, 84).—6. Hydrogen peroxide and  $\text{H}_2\text{SO}_4$  produce salicylic acid (Hanriot, *C. R.* 102, 1250).—7. Vapours of benzoic acid passed over heated zinc dust form benzoic aldehyde (Bayer, *A.* 110, 225).—8. Sodium amalgam reduces it to benzyl alcohol, and benzoic acid  $\text{C}_6\text{H}_5\text{CO}_2\text{Na}$  and an oil  $\text{C}_6\text{H}_5\text{O}_2$  (Kolbe, *A.* 118, 122; Hermann, *A.* 132, 75).—9.  $\text{PCl}_5$  forms benzoyl chloride.—10. Distillation with  $\text{KSCN}$  or  $\text{Pb(SCN)}_2$  gives benzonitrile.—11. Benzene and  $\text{P}_2\text{O}_5$  at  $190^\circ$  give *p*-azophenone (Kollarits a. Merz, *B.* 5, 447).—12. Dimethylaniline and  $\text{P}_2\text{O}_5$  give  $\text{C}_6\text{H}_5\text{CO}_2\text{C}_6\text{H}_4\text{NMe}_2$  (O. Fischer, *B.* 10, 958).—13. Chlorine produces chloro-benzoic acids.—14. Bromine forms bromo-benzoic acids.—15. Iodine in presence of  $\text{HIIO}$  forms iodobenzoic acid.—16. Cone.  $\text{HNO}_3$  forms *m*-nitro-benzoic acid.—17. Fuming  $\text{H}_2\text{SO}_4$  forms sulphobenzoic acid.—18. In the animal organism it is converted into hippuric acid and excreted in the urine (Wöhler).—19.  $\text{CrF}_3$  forms di-fluoro-benzoic acid (Jackson a. Hartshorn, *B.* 18, 1333).

**Salts.**—Benzoic acid decomposes carbonates, but an alcoholic solution of potassium benzoate is decomposed by  $\text{CO}_2$ . Calcium benzoate gives on distillation benzophenone, and smaller quantities of benzene, anthraquinone,

and tetra-phenyl-methane (Kekulé a. Fremont, *B.* 5, 909). Calcium benzoate distilled with calcium formate gives benzoic aldehyde. Potassium benzoate distilled alone or with sodium formate gives terephthalic and isophthalic acids (Richter, *B.* 6, 876; Conrad, *B.* 6, 1395). Cupric benzoate gives on distillation benzene, benzoic acid, di-phenyl oxide  $\text{Ph}_2\text{O}$ , phenyl benzoate  $\text{PhO}_2\text{C}$ , and phenol (List a. Limpriht, *A.* 90, 190). Cyanogen bromide acts upon potassium benzoate thus:  $\text{PhCO}_2\text{K} + \text{CNBr} = \text{PhCN} + \text{CO}_2 + \text{KBr}$  (Cahours, *A. Ch.* [3] 52, 201). Potassium benzoate when electrolysed gives K and benzoic anhydride; in presence of excess of  $\text{KOH}$  acetylene is also formed (Bourgoin, *Z.* [2] 4, 566).

$\text{Al}_2\text{A}_3(\text{OH})_3$ , aq.: crystals (Sestini, Cicognani, a. Zavatti, *B.* [2] 13, 488).— $\text{NH}_4\text{A}$ : deliquescent; on distillation it gives benzonitrile. —  $\text{NH}_4\text{A}$ , 2aq. —  $\text{CdA}$ , 2aq. —  $\text{CaA}$ , 3aq.: S. 3.6. —  $\text{CeA}$ , 3aq. —  $\text{CoA}$ , 2aq. —  $\text{CuA}$ , 2aq.: needles. —  $\text{CrA}$ , 2aq. —  $\text{CrA}$ , 2aq. —  $\text{CrA}$ , 2aq. —  $\text{FeA}$ , 2aq.: buff-coloured pp. —  $\text{LaA}$ , 3aq. —  $\text{PbA}$ , 2aq.: plates. —  $\text{PbA}$ , 2aq. —  $\text{MgA}$ , 3aq.: S. 4.5 at  $25^\circ$ . —  $\text{MnA}$ , 3aq.: large flat prisms, S. 6.55 at  $15^\circ$  (Senbert, *B.* 20, 791). —  $\text{Hg}_2\text{A}$ , aq. —  $\text{Hg}_2\text{A}$ , —  $\text{NiA}$ , 3aq. —  $\text{AgA}$ : S. (alcohol) 5 at  $20^\circ$ . —  $\text{NaA}$ , aq. —  $\text{SnA}$ , aq. —  $\text{ZnA}$ .

**Methyl ether**  $\text{C}_6\text{H}_5\text{CO}_2\text{Me}$ . Mol. w. 136. (199°) (Kopp); (195.5) at 768 mm. (Stohmann, *J. pr.* [2] 36, 4). S.G. 1.10 (Kopp); 1.0862 (Brühl). S.V. 119.8 (Raunay). S.H. 363 + 0.00754. I.F. 84,024 (S.).  $\mu$  1.5290.  $n_D^{20}$  1.4130 (B.). Formed by distilling wood spirit (1 pt.), benzoic acid (2 pts.), and  $\text{H}_2\text{SO}_4$  (2 pts.) (Dumas a. Peligot, *A. Ch.* [2] 58, 50; Malaguti, *A. Ch.* [2] 70, 387; Carus, *A.* 110, 210).

**Ethyl ether**  $\text{C}_6\text{H}_5\text{CO}_2\text{Et}$ . Mol. w. 150. V.D. 5.53 (calc. 5.2) (Troost, *C. R.* 89, 851). (211.2° cor.) (Linnemann, *A.* 160, 208); (211.4°) (Stohmann, *J. pr.* [2] 36, 4). S.G. 1.0473 (Brühl); 1.050 (L.). S.H. 374 + 0.00754 (B. Schiff, *A.* 234, 300). I.F. 91,693 (St.).  $\mu$  1.517 (B.).  $n_D^{20}$  1.4144 (B.). Formed by saturating a solution of benzoic acid (3 pts.) in alcohol (2 pts.) with  $\text{HCl}$  and distilling the liquid. Converted by  $\text{Br}$  at  $270^\circ$  into benzoic acid and ethylene bromide (Naumann, *A.* 133, 199). Forms crystalline compounds with titanio chloride:  $\text{BzOEtTiCl}_3$ ,  $\text{C}_2\text{H}_5\text{OEt}_2\text{TiCl}_2$ . —  $\text{TiCl}_4$ ,  $2\text{BzOEt}$  (Demarecy, *C. R.* 70, 1414), and with aluminium chloride:  $\text{BzOEtAlCl}_2$  (Gustafson, *B.* 13, 157; Scheele, *Opuscula*, 2, 141; Dumas a. Boullay, *A. Ch.* [2] 87, 20; Wöhler a. Liebig, *A.* 3, 274; Deville, *A. Ch.* [3] 3, 188).

**Propyl ether**  $\text{C}_6\text{H}_5\text{CO}_2\text{Pr}$ . (230°). S.G. 1.032 (L.); 1.025 (S.). I.F. 98,990 (Stohmann, *J. pr.* [2] 36, 4). S.H. 383 + 0.00754 (Schiff, *A.* 234, 300).

**Isopropyl ether**  $\text{C}_6\text{H}_5\text{CO}_2\text{Pr}$ . (218°). S.G. 1.023 (Silva, *B.* 12, 225). According to Linnemann (*A.* 161, 51) the ether splits up on distillation into propylene and benzoic acid.

**n-Butyl ether**  $\text{C}_6\text{H}_5\text{CO}_2\text{C}_4\text{H}_9$ . (247.3° cor.). S.G. 1.00.

**Isobutyl ether**. (234°) at 755 mm. S.G. 1.002. I.F. 105,628 (St.).

**Isoamyl ether**  $\text{C}_6\text{H}_5\text{CO}_2\text{C}_5\text{H}_{11}$ . Mol. w. 192. (261°) (Kopp, *A.* 94, 311); (253°) (Stohmann, *J. pr.* [2] 36, 4). V.D. 6.71 (calc. 6.65,

Troost, *C. A.* 39, 351). S.G. 1.004 (K.); 1.003 (K.). H.C. 1.870, 0.48 (St.).

Formed by heating ethyl benzoate with isomyl alcohol at 230° for 60 hours (Friedel & Crafts, *Bl.* [2] 3, 100).

*Octyl ether*  $C_8H_{17}.CO.C_8H_{17}$ . (306°) (Zincke, *A.* 152, 7).

*Decyl ether*  $C_{10}H_{21}.CO.C_{10}H_{21}$ . (over 290°) (Borodin, *J.* 1864, 338).

*Cetyl ether*  $C_{18}H_{37}.CO.C_{18}H_{37}$ . [30°] (Becker, *A.* 102, 221).

*Allyl ether*  $C_3H_5.CO.C_3H_5$ . (242°) (Zimin, *A.* 96, 362); (230°) (Berthelot & de Luca, *A.* 100, 360); (280°) (Cahours & Hofmann, *A.* 102, 297).

*Ethylene ether*  $(C_2H_5.CO)_2.C_2H_5$ . [67°] (360°).

*Propylene ether*  $(C_3H_7.CO)_2.C_3H_7$ . [72°] (300°).

*Isomylene ether*  $(C_5H_9.CO)_2.C_5H_9$ . [133°] (Mayer, *Bl.* [2] 2, 151).

Other ethers of benzoic acid are described as benzoyl derivative of the hydroxylic compounds from which they may be derived.

References.—V. also ALDEHYDE, AMIDO-, BROMO-, BROMO-AMIDO-, BROMO-NITRO-, BROMO-NITRO-OXY-, BROMO-OXY-, BUTYL-, CHLORO-, CHLORO-AMIDO-, CHLORO-OXY-, CYANO-, FLUORO-, IODO-, IODO-OXY-, NITRO-, NITRO-BUTYL-, NITRO-OXY-, NITRO-PROPYL-, OXY-, SULPHO-, BENZOIC ACID.

Orthobenzoic acid  $C_6H_4.C(OH)_2$ . Benzoyl alcohol.

*Ethyl ether*  $C_2H_5.C(OEt)_2$ . (220°–225°). From benzotrichloride and NaOEt at 100° (Lamprecht, *A.* 135, 87).

*Tri-acetyl derivative*  $C_6H_5.C(OAc)_3$ . From  $C_6H_5.CCl_3$  and  $AgOAc$ . Readily splits up into  $Ac_2O$  and  $C_6H_5.CO.OAc$ .

Sulphinide of benzoic acid v. IMIDE OF SULPHOBENZOIC ACID.

**BENZOIC ALDEHYDE**  $C_6H_5.O$  i.e.  $C_6H_5.CO.H$ . *Benzaldehyde*. Oil of bitter almonds. Mol. w. 106. (179°). S.G. 1.0455 (Brühl); 1.0504 (Mendeleff, *J.* 1860, 7). S. 33 (Flückiger, *J.* 1875, 482).  $\mu_s$  1.5621.  $n_D^{20}$  1.5165 (H.). H.F. 23.254 (Stohmann, *J. pr.* [2] 36, 3).

Formation.—1. From almonds (*q. v.*).—

2. By oxidation of benzyl alcohol (Cannizzaro, *A.* 89, 130), cinnamic acid (Dumas & Peligot, *A.* 14, 50), and proteids (Guckelberger, *A.* 64, 60, 72, 86).—3. By boiling benzyl chloride with water and nitrate of lead (Lauth & Grimaux, *A.* 143, 80), nitrate of copper, or sodium nitrate.

4. By heating benzylidene chloride with water or alkalis (Cahours, *C. R.* 56, 222).—5. By mixing benzylidene chloride with conc.  $H_2SO_4$ , diluting, and distilling (Oppenheim, *Z.* [2] 5, 411).

6. By passing vapour of benzoic or phthalic acid over heated zinc dust (Bayer, *A.* 119, 295).

7. By reducing benzoic acid with  $SnCl_4$  (Dbsart, *J.* 1862, 263), or sodium amalgam in slightly acid solution (Kolbe, *A.* 118, 122).—8. By distilling calcium benzoate with calcium formate (Piria, *A.* 100, 104).—9. From benzylidene chloride and silver oxalate (Golowinsky, *A.* 111, 252) or potassium carbonate (Meunier, *Bl.* [2] 38, 159).

10. From toluene by successive treatment with  $CrO_2Cl_2$  and water (Etard, *C. R.* 90, 534).—

11. From benzylidene chloride, acetic acid, and  $ZnCl_2$ :  $Ph.CHCl_2 + CH_3.CO.H \rightarrow Ph.CHO + CH_3.COCl + HCl$

Preparation.—1. Benzyl chloride (1 pt.) is coheated at 100° with water (10 pts.) and lead nitrate ( $\frac{1}{2}$  pts.), a current of  $CO$ , being passed through the apparatus. The product is distilled and the light oil fractionated. It is shaken with a saturated solution of  $NaHSO_4$ , and the resulting crystalline compound is washed with alcohol, crystallised from water, and then decomposed by boiling aqueous  $Na_2CO_3$  (Lauth & Grimaux, *A.* 143, 80; Bertagnini, *A.* 85, 183).—2. Crude benzylidene chloride is heated at 110°–130° with an equivalent quantity of dry oxalic acid, the product is distilled *in vacuo*:  $Ph.CHCl_2 + H_2C_2O_4 \rightarrow Ph.CHO + 2HCl + CO$ ,  $CO$  (Anschütz, *A.* 226, 18).—3. A mixture of benzyl chloride (2 mols.) with benzylidene chloride (1 mol.) obtained by chlorinating toluene till the S.G. is 1.175 is boiled with water and  $MnO_2$  (2 mols.) (Schmidt).—4. By heating benzylidene chloride with aqueous  $KOH$  under pressure, or by boiling it with milk of lime. 5. Bitter almonds are freed from almond oil by pressure. The press-cake (12 pts.) is made into a paste with boiling water (110 pts.); after 15 minutes the paste is allowed to cool. The emulsion is destroyed by boiling, and therefore a second quantity of the press-cake (1 pt.) is mixed with cold water (6 pts.) and added to the first. After 12 hours' maceration the whole is distilled with steam. The yield is 2 p.c. of the press cake (Pettenkofer, *A.* 122, 77; cf. Liebig & Wöhler, *A.* 22, 1). In this operation amygdalin is split up by the unorganised ferment emulsin, the products being benzoic aldehyde, prussic acid, and glucose:

Benzoic aldehyde so prepared contains prussic acid, which appears to be combined in the form of the cyanhydrin  $C_6H_5.CH(OH).CN$ , for a mixture of benzoic aldehyde and prussic acid yields methylamine on reduction, while crude oil of bitter almonds yields anilic phenyl-ethane  $C_6H_5.CH_2.CH_2.NH_2$ ; again, a mixture of benzoic aldehyde and prussic acid, on treatment with chlorine, yields  $C_6H_5.Cl.CO.Cl$ , while oil of bitter almonds yields, by similar treatment,  $C_6H_5.CH(OH).CO.NHCl.C_6H_5$  (Fiolet, *C. R.* 9, 446). Prussic acid may be removed by shaking with  $FeSO_4$  and lime or potash, or by digesting with  $H_2O$  and water. The aldehyde is then purified by means of  $NaHSO_4$  as described under 1.

Properties.—Colourless oil. It is not poisonous. It oxidises rapidly in the air, but the addition of a little prussic acid hinders the oxidation (Dusart, *Bl.* 8, 459). It does not reduce Fehling's solution.

Reactions.—1. Oxidised to benzoic acid by air or other oxidising agents. Conc.  $HNO_3$ , however, forms  $\alpha$ - (and a little  $\beta$ ) nitro-benzaldehyde.—2. Aqueous or alcoholic potash gives benzyl alcohol and potassium benzoate.—3. Led over red-hot pumice it is split up into  $CO$  and benzene (Barreswil & Boudault, *A.* 62, 260).—4.  $PCl_5$  forms benzylidene chloride (Cahours, *A.* 70, 39).  $COCl_2$  acts similarly (Kemp, *J. pr.* [2] 1, 412).—5. Chlorine forms benzoyl chloride and a compound of that body with benzoic aldehyde,  $C_6H_5.CHCl(OBz)$  (Laurent & Gerhardt, *J.* 1850, 489). Bromine acts similarly, forming  $C_6H_5.CHBr(OBz)$  (70°) (Liebig & Wöhler, *A.* 8, 266; Claisen, *B.* 14, 2475).—6. Succinyl chlo-

ride produces succinic acid and benzylidene chloride (Bembold, *A.* 138, 189).—7. *Sodium amalgam* reduces it, in presence of water, to benzyl alcohol, hydrobenzoin, and isohydrobenzoin.—8. *Potassium cyanide* produces benzoin.—9. Aqueous  $\text{HI}$  (S.G. 2.0) at  $280^\circ$  reduces it to toluene (Berthelot, *J.* 1867, 346).—10.  $\text{H}_2\text{S}$  forms thiobenzaldehyde.—11. Aqueous  $\text{NH}_3$  forms hydrobenzamide  $(\text{C}_6\text{H}_5\text{CH}_2)_2\text{N}_2$ .—12. *Ammonium sulphide* forms thiobenzaldimine  $\text{C}_6\text{H}_5\text{NHS}$ .—13.  $\text{NH}_3$  and sulphide of carbon form  $\text{NH}_2\text{CSSN}(\text{CH}_2\text{C}_6\text{H}_5)_2$ .—14. With *acetic anhydride* and *sodium acetate*, on heating, it forms sodium cinnamate (v. PERRIN'S SYNTHESIS, p. 108). The reaction probably takes place in two stages:  $\text{C}_6\text{H}_5\text{CHO} + \text{CH}_3\text{CO}_2\text{Na} =$

$\text{C}_6\text{H}_5\text{CH}(\text{OH})\text{CH}_2\text{CO}_2\text{Na} =$   
 $\text{H}_2\text{O} + \text{C}_6\text{H}_5\text{CH}(\text{CH}_2\text{CO}_2\text{Na})$ .—15. With  $\text{Ac}_2\text{O}$  and *sodium succinate* it gives the lactone of  $\text{CO}_2\text{HCH}_2\text{CH}(\text{CO}_2\text{H})\text{CH}(\text{OH})\text{C}_6\text{H}_5$ .—16. With *sodium isobutyrate* and *isobutyric anhydride* it forms  $\text{C}_6\text{H}_5\text{CH}(\text{OH})\text{CH}(\text{O})\text{CMe}_2\text{CO}_2\text{H}$ , v. OXY-PHENYL-VALERIC ACID (Pittig, *A.* 216, 119).—17. With  $\text{Ac}_2\text{O}$  and *sodic butyrate* at  $100^\circ$  it gives only phenyl-angelic acid, whereas at  $180^\circ$  the chief product is cinnamic acid (Slocum, *A.* 227, 53).—18. The reaction  $\text{PhCHO} + \text{CH}_3\text{XY} =$   
 $\text{H}_2\text{O} + \text{PhCH}(\text{CXY})$  takes place under influence of dry  $\text{HCl}$  or aqueous or alcoholic  $\text{KOH}$  on condition that  $\text{X}$  or  $\text{Y}$  is of the form  $\text{CO}_2\text{Z}$ , e.g. benzoic aldehyde acting on acetone, mesityl oxide, acetophenone, pyruvic acid, malonic ether, and aceto-acetic ether. Perkin's reaction is of a similar nature. Occasionally intermediate compounds of the form  $\text{PhCH}(\text{OH})\text{CHXY}$  are formed (Claisen, *A.* 218, 121).—19. *Sodium malonate* and  $\text{Ac}_2\text{O}$  react in the cold, giving off  $\text{CO}_2$  and forming cinnamic acid, as follows:  $\text{PhCHO} + \text{CH}_2(\text{CO}_2\text{H})_2 = \text{PhCH}(\text{C}(\text{CO}_2\text{H})_2) + \text{H}_2\text{O} = \text{PhCH}(\text{CH}_2\text{CO}_2\text{H}) + \text{CO}_2 + \text{H}_2\text{O}$  (Stuart, *J.* 43, 404).—20. *Sodium isosuccinate* and  $\text{Ac}_2\text{O}$  act similarly, forming phenyl-iso-crotonic acid:  $\text{PhCHO} + \text{CHMe}(\text{CO}_2\text{H})_2 =$   
 $\text{PhCH}(\text{CMe}(\text{CO}_2\text{H})_2) + \text{CO}_2 + \text{H}_2\text{O}$ .

21. *Acetyl chloride* and *zinc dust* form diacetyl-hydrobenzoin; while benzoyl chloride and zinc dust form di-benzoyl-hydrobenzoin (Paul, *B.* 15, 1818; 16, 636; 17, 909).—22. Reacts with *nitro-paraffins* thus:  $\text{PhCHO} + \text{H}_2\text{C}(\text{NO}_2)_2\text{CH}_3 =$   
 $\text{H}_2\text{O} + \text{PhCH}(\text{C}(\text{NO}_2)_2\text{CH}_3)$  (Priebs, *A.* 225, 319).—23. A solution of *aniline* in conc.  $\text{HCl}$  pps. yellow crystals of a molecular compound. They are only stable in presence of conc.  $\text{HCl}$  (Elbers, *A.* 227, 367). If  $\text{SnCl}_4$  be also present a compound  $(\text{NPh}_2\text{HCl})_2(\text{C}_6\text{H}_5\text{O})_2\text{SnCl}_4$  is formed (E.).—24. *Aniline* forms benzylidene-aniline,  $\text{C}_6\text{H}_5\text{CH}(\text{N}(\text{C}_6\text{H}_5)_2)$ ; *o-toluidine* acts similarly. When heated in presence of  $\text{HCl}$  or  $\text{ZnCl}_2$  aniline forms di-amido-tri-phenyl-methane. *Dimethylaniline* in presence of  $\text{ZnCl}_2$  gives  $\text{C}_6\text{H}_5\text{CH}(\text{C}_6\text{H}_4\text{NMe}_2)_2$  (Fischer, *B.* 10, 1623); *dimethyl m-* (but not *o-* or *p-*) *toluidine* behaves similarly (Fischer, *B.* 13, 807).—25. *Ethylene-diamine* forms  $(\text{C}_6\text{H}_5\text{CH}(\text{N})_2)_2\text{C}_2\text{H}_4$  [54°] (Mason, *B.* 20, 267).—26. *(8-Naphthylamine* forms benzylidene-(8)-naphthylamine and then phenyl-naphthaeridine dihydride  $\text{PhCH}(\text{C}_6\text{H}_4)_2\text{NH}$  (Claisen, *A.* 237, 261).—27. *Resorcin* in presence of  $\text{HCl}$  forms a resin  $\text{C}_{20}\text{H}_{12}\text{O}_4$  (Baeyer, *B.* 5, 25). *Phenol*, *pyrocatechin*, *phloroglucin*,

*cin*, and *orein* act similarly (Michael & Ryder, *B.* 19, 1388; *Am.* 9, 130).—28. *(8-Naphthol* left to stand for several days in the cold with an acetic acid solution of benzaldehyde treated with a few drops of  $\text{HCl}$  forms di-(8)-naphthyl benzaldehyde (di-naphthyl-ortho-benzoic aldehyde)  $\text{C}_{10}\text{H}_7\text{CH}(\text{OC}_6\text{H}_4)_2$  [205°]. It is a crystalline pp., sl. sol. all ordinary solvents; insol. aqueous alkalis. By warming with acetic acid and a few drops of  $\text{HCl}$  it is converted into the isomeric di-oxy-di-naphthyl-phenyl-methane  $\text{C}_{10}\text{H}_7\text{CH}(\text{C}_6\text{H}_4\text{OH})_2$ , which at the same time loses  $\text{H}_2\text{O}$ , giving the compound  $\text{C}_{10}\text{H}_7\text{CH}(\text{C}_6\text{H}_4)_2\text{O}$  (Claisen, *B.* 19, 3317).—

29. *Acetone* in presence of aqueous  $\text{NaOH}$  produces  $\text{C}_6\text{H}_5\text{CH}(\text{CH}_3)\text{CO}_2\text{CH}_3$  and the compound  $\text{C}_6\text{H}_5\text{CH}(\text{CH}_3)\text{CO}_2\text{CH}(\text{CH}_3)_2$ . In general, compounds containing the group  $\text{CH}_2\text{CO}$  react with benzoic aldehyde, exchanging the  $\text{H}$  for  $\text{CHPh}$  (Claisen, *B.* 14, 349, 2468; v. BENZYLIDEN-ACETONE).—30. *Prussic acid* forms mandelonitrile or the cyanhydrin of benzoic aldehyde,  $\text{C}_6\text{H}_5\text{CH}(\text{OH})\text{CN}$  (v. MANDelic ACID). This is converted by alcohol and  $\text{HCl}$  into mandelic imido-ether,  $\text{C}_6\text{H}_5\text{CH}(\text{OH})\text{C}(\text{NH})\text{OEt}$  (Völckel, *A.* 52, 361; Tiemann, *B.* 14, 1967). Benzoic aldehyde (4 vols.) mixed with nearly anhydrous prussic acid (1 vol.) and shaken with alcoholic  $\text{KOH}$  forms benzimide  $\text{C}_6\text{H}_5\text{N}_2\text{O}$  [167°], a flocculent substance, insol. water, alkalis, and acids (Laurent, *A. Ch.* [2] 59, 397; 66, 193; Zinin, *A.* 34, 188; *B.* 2, 552; Gregory, *A.* 54, 372).—31. *Hydrogen iodide* forms a pungent compound  $\text{C}_6\text{H}_5\text{I}_2\text{O}$  [28°] insol. water (Genther & Cartmell, *A.* 112, 20).—32.  $\text{SO}_3$  forms a disulphonic acid  $\text{C}_6\text{H}_4(\text{SO}_3\text{H})_2\text{CHO}$  (Engelhardt, *J.* 1864, 350).—33. By treatment with a methyl-alcoholic solution of *sodium methylate* a white solid compound  $\text{C}_6\text{H}_5\text{C}(\text{OMe})_2(\text{OC}_6\text{H}_5)_2(\text{ONa})$  is formed. The same body is formed by the action of *sodium methylate* on benzyl-benzoate or of *sodium benzyolate* on methyl-benzoate. By treatment with acetic acid it is split up into a mixture of benzyl benzoate, methyl benzoate, benzyl alcohol, and methyl alcohol.—34. If benzaldehyde is heated with a small quantity of *sodium benzyolate* for several days at  $100^\circ$ , it is slowly polymerised to benzyl benzoate. Probably the compound  $\text{C}_6\text{H}_5\text{C}(\text{OC}_6\text{H}_5)_2\text{ONa}$  is first formed, and then decomposes into benzyl benzoate and *sodium benzyolate*, which latter again reacts upon a further quantity of benzaldehyde, producing more of the intermediate compound, and so on (Claisen, *B.* 20, 646).—35. By boiling with *ammonium formate* it yields tri-, di-, and mono-benzyl-amine and their formyl derivatives, together with other products (Leuchart, *B.* 19, 2128).—36. *Ammonium sulphocyanide* at  $140^\circ$  forms benzylidene-thio-biuret  $\text{C}_6\text{H}_5\text{CH}(\text{NHCS})_2\text{NH}$  [237°] (Brodsky, *M.* 8, 27).—37. *Benzene-azo-benzene* and  $\text{ZnCl}_2$  forms 'benzylidene-benzidine'  $\text{C}_6\text{H}_5\text{N}_2\text{C}_6\text{H}_5$  [239°] (Barzilowsky, *J. R.* 1885, 366).—38. Acts upon an alcoholic solution of *sodium aceto-acetic ether*, forming  $\text{C}_{22}\text{H}_{18}\text{O}$  [127°], sol. dilute alkalis (Michael, *J. pr.* [2] 35, 450).—39. *Hydrazine-benzoic acid*,  $\text{NH}_2\text{NH}(\text{C}_6\text{H}_4)_2\text{CO}_2\text{H}$ , forms benzylidene-hydrazine-benzoic acid  $\text{C}_{10}\text{H}_7\text{N}_2\text{O}_4$  [172° uncor.] (Röder, *A.* 236, 171).

*Formation.*—1. By the action of ammonia upon an alcoholic solution of benzoic aldehyde

(Laurent, *C. R.* 19, 858).—3. By boiling hydrobenzamide with aqueous potash (Fownes, *T.* 1845, 268).—8. By heating hydrobenzamide to 120°–180° (Bertagnini, *A.* 88, 127).—4. Together with lophine by distilling the double compound of benzoic aldehyde and ammonium hydrogen sulphite with excess of slaked lime (Gössmann, *A.* 93, 329).—6. In small quantity when ammonia acts upon a mixture of benzoic acid and benzoic aldehyde:  $-C_6H_5O_2 + C_6H_5O + 2NH_3 = C_6H_5N_2 + 3H_2O$  (Radziszewski, *B.* 15, 1495).

**Preparation.**—Hydrobenzamide is heated from 2 to 4 hours at 120°–130°. The vitreous mass thus obtained is dissolved in boiling alcohol, and an excess of hydrochloric acid is added. The amarine hydrochloride, which separates in white crystals, is purified by recrystallising from boiling alcohol and is then decomposed with ammonia.

**Properties.**—Deposited from alcohol in lustrous prisms. Melts at 100° (Fownes), but by boiling for some time with water, is converted into a granular substance melting as high as 126°. This modification is reconverted into prismatic amarine, melting at 100°, by recrystallisation from alcohol (Claus, *B.* 18, 1678). Insol. water, v. sol. alcohol and ether; the alcoholic solution having an alkaline reaction. Has a bitter taste, which is noticeable only after a time. Very poisonous. Combines with acids to form sparingly soluble salts which have an intensely bitter taste.  $-C_6H_5N_2.HCl$ . Needles, sparingly soluble in boiling water.  $-(C_6H_5N_2.HCl)_2.PtCl_2$ . Yellow crystalline salt (Gössmann).  $-C_6H_5N_2.HI$  (Borodine, *A.* 110, 79).  $-C_6H_5N_2.HNO_3$  (Fownes).  $(C_6H_5N_2)_2.H_2SO_4 + 8H_2O$  (Groth, *A.* 152, 122).  $-(C_6H_5N_2)_2.H_2CrO_4$ . Yellow precipitate, almost insol. water.

**Reactions.**—1. By destructive distillation it yields ammonia, toluene, and lophine,  $C_6H_5N_2$  (Fownes; v. also Radziszewski, *B.* 10, 70).—2. By limited oxidation, as when the chromate is boiled with glacial acetic acid, it is converted into lophine:  $C_6H_5N_2 + O = C_6H_5N_2 + H_2O$  (Fischer a. Troschke, *B.* 13, 707). Excess of chromic acid oxidises it to benzoic acid. 3. When a hot alcoholic solution of amarine is acidified with acetic acid and a hot concentrated solution of an alkaline nitrite is added, nitroso-amarine,  $C_6H_5(NO)N_2$ , separates, and, by recrystallisation from alcohol, may be obtained in rhombic tables, which, when heated to 150°, decompose with formation of lophine (Borodine, *B.* 8, 934).—4. With nitric acid in the cold, mononitro-amarine,  $C_6H_5(NO)N_2$ , is formed; hot nitric acid converts it into dinitro-amarine,  $C_6H_5(NO_2)_2N_2$ . The latter compound yields, with reducing agents, diamido-amarine,  $C_6H_5(NH_2)_2N_2$ . Salts of these nitro- and amido- bases have been prepared (Claus a. Witt, *B.* 18, 1670).—5. With acetyl chloride an ethereal solution of amarine yields a product which, when treated with alcohol, is separated into amarine hydrochloride and diacetyl amarine,  $C_6H_5(C_2H_3O)_2N_2$  [268°] (Bahrmann, *J. pr.* [2] 27, 295).—6. Amarine reacts with the halogen compounds of the alkyls to form substitution- and addition- compounds. Thus when amarine, methyl iodide, and ether are allowed to stand together in the cold, methyl-amarine hydriodide,  $C_6H_5.Me.N_2.HI$ , is formed.

Ammonia is without action upon this salt, but alcoholic potash liberates methylamarine [164°]. When amarine is heated with methyl iodide, a dimethylamarine hydriodide,  $C_6H_5.Me_2N_2.HI$ , is formed. Like the monomethyl compound it is not decomposed by ammonia; by treatment with alcoholic potash, dimethylamarine [146°] is obtained, and this base unites with hydriodic acid to form a hydriodide isomeric with the foregoing and differing from it in being decomposed by ammonia even in the cold (Claus a. Elbs, *B.* 13, 1418). Dimethylamarine and the other dialkyl-amarines do not combine with the halogen compounds of the alkyls.

**Further derivatives of amarine.**—*Ethylamarine*,  $C_6H_5.Et.N_2$  [163°] (Claus a. Scherbel, *B.* 18, 3080); *diethylamarine*,  $C_6H_5.Et_2N_2$  [110°–115°] (Borodine, *A.* 110, 82); *Benzylamarine*,  $C_6H_5(C_6H_5)N_2$  [123°–124°]; *dibenzylamarine*,  $C_6H_5(C_6H_5)_2N_2$  [139°–140°] (Claus a. Elbs, *B.* 13, 1418; Claus, *B.* 15, 2330; Claus a. Kohlstock, *B.* 18, 1819); *Ethylbenzylamarine*,  $C_6H_5.Et(C_6H_5)N_2$  [135°] (C. a. K.); *Hydro-methylbenzylamarine*,  $C_6H_5.Me(C_6H_5)N_2$  [208°]; *hydrotrimethylamarine*,  $C_6H_5.Me_3N_2$  [158°] (Claus, *B.* 15, 2326).—Other derivatives:  $C_6H_5N_2(C_2H_5O).OKt$ ;  $C_6H_5N_2(CO_2Et)_2$ ; and  $C_6H_5N_2(CO_2Et)(CONHEt)$  (Bahrmann, *J. pr.* [2] 27, 295).—*Amarine-silver*,  $C_6H_5.AgN_2$  (Claus a. Elbs, *B.* 16, 1272); *diamarine silver nitrate*,  $(C_6H_5N_2)_2.AgNO_3$  aq [218°] (C. a. K.).

When amarine silver is mixed with one molecular proportion of an alkyl-halogen compound (the latter diluted with benzene) and allowed to stand in the cold, a double compound of amarine-silver with the alkyl-halogen is obtained. At the same time a small quantity of monalkylamarine is formed from the double compound by elimination of silver iodide. In this way the following compounds have been prepared (Claus a. Scherbel, *B.* 18, 3077): *amarine-silver methylo-iodide*,  $C_6H_5.AgN_2.CH_3I$  [173°]; *amarine-silver ethylo-iodide*,  $C_6H_5.AgN_2.C_2H_5I$  [115°]; *amarine-silver isopropyl-bromide*,  $C_6H_5.AgN_2.C_3H_7Br$  [140°]; and finally *amarine-silver benzyl-chloride*,  $C_6H_5.AgN_2.C_6H_5Cl$  [250°]. When amarine-silver is treated with benzoyl chloride it yields *benzoyl-amarine*,  $C_6H_5(C_6H_5O)N_2$  [180°], which forms salts with acids and also unites with benzoyl chloride to form *benzoyl-amarine benzoyl chloride*,  $C_6H_5(C_6H_5O)N_2.C_6H_5OCl$  [312°], and with benzyl chloride to form *benzoyl-amarine benzyl-chloride*,  $C_6H_5(C_6H_5O)N_2.C_6H_5Cl$  [351°], which latter is isomeric with *benzyl-amarine benzoyl chloride*,  $C_6H_5(C_6H_5)N_2.C_6H_5OCl$  [340°–350°], obtained by the action of benzoyl chloride upon benzyl-amarine. The bases corresponding with these two chlorides are also isomeric. Benzoyl-amarine also unites with methyl iodide and with ethyl iodide to form additive compounds melting at 318° and 354° respectively (C. a. S.).

*Triphenylglyoxaline* (Japp a. Robinson, *C. J.* 41, 323). [275°].

**Formation.**—1. By the destructive distillation of hydrobenzamide (Laurent, *A. Ch.* 19, 389), of amarine (Fownes, *T.* 1845, 263), or of tribenzylamine (Brunner, *A.* 151, 136). By the limited oxidation of amarine with chromic

acid (E. Fischer & Troschke, *B.* 15, 706).—  
3. By passing ammonia into a warm alcoholic solution of a mixture of benzil and benzoic aldehyde:

(Radziszewski, *B.* 15, 1493; cf. Japp, *B.* 15, 2410).—4. By heating together *p*-oxybenzoic aldehyde, benzil, and ammonia, *p*-oxy-lophine,  $C_{10}H_{11}(OH)N_3$ , is formed (v. BENZIL, AMMONIA-DERIVATIVES OF, p. 466); and this, by distillation with zinc-dust, is converted into lophine (Japp & Robinson, *C. J.* 41, 323).—5. By warming cyanphenine,  $C_{10}H_{11}N_3$ , with acetic acid and zinc dust, or by distilling it with potash and iron filings, it is converted into lophine and ammonia:  $C_{10}H_{11}N_3 + 2H_2 = C_6H_5N_3 + NH_3$  (Radziszewski).

**Preparation.**—Hydrobenzamide is heated in a retort until the more volatile products of its decomposition—hydrogen, ammonia, and toluene—have been given off. The residue, which can only be distilled at a high temperature, is treated with ether, and then dissolved in glacial acetic acid. From this solution water precipitates lophine, which is finally purified by recrystallising it from boiling alcohol (Radziszewski, *B.* 10, 70).

**Properties.**—Crystallises in very slender, colourless silky needles [275°] (Radziszewski). Distils without decomposition at a high temperature. The vapour-density agrees with the formula  $C_{10}H_{11}N_3$  (Fischer & Troschke). Insol. water, sl. sol. alcohol and ether. Its solution in alcoholic potash phosphoresces when air is admitted, owing to a process of oxidation, in which the lophine is slowly converted into benzoic acid and ammonia (Radziszewski). Feebly basic: the salts are partially decomposed by water, in which they are for the most part insoluble; but they may be crystallised from alcohol.

**Salts.**—(Laurent, *A. Ch.* 19, 369; Atkinson & Gössmann, *A.* 97, 283; Brunner, *A.* 151, 135).  $C_{10}H_{11}N_3.HCl$ , aq.: obtained by adding hydrochloric acid to an alcoholic solution of lophine. According to Laurent and Brunner this salt is anhydrous.— $C_{10}H_{11}N_3.2HCl$ : formed by the action of gaseous hydrochloric acid upon lophine.— $(C_{10}H_{11}N_3.HCl).PtCl_4$ : rhombic plates. Contains  $5H_2O$  (Brunner).— $C_{10}H_{11}N_3.HI$ .— $C_{10}H_{11}N_3.HNO_3$ .—With silver nitrate it gives rise to:  $C_{10}H_{11}N_3.AgNO_3$ ;  $2C_{10}H_{11}N_3.AgNO_3$ ; and  $2C_{10}H_{11}N_3.3AgNO_3$  (A. a. G.).

**Reactions.**—1. Oxidation with chromic acid in acetic acid solution converts lophine into a mixture of benzamide and dibenzamide:

(Fischer & Troschke).—2. By the action of bromine upon lophine hydrobromide, an unstable perbromide of the formula,  $C_{10}H_{11}N_3.Br_4$ , is obtained (F. a. T.).—

3. **Nitric acid** yields, according to temperature and concentration, either *di*-nitrolophine,  $C_{10}H_{11}(NO_2)_2N_3$ , or *tri*-nitrolophine  $C_{10}H_{11}(NO_2)_3N_3$  (Laurent; Ekmann, *A.* 112, 161).—4. Heated with concentrated sulphuric acid to 160°–170° lophine is converted into lophine-disulphonic acid,  $C_{10}H_{11}N_3(SO_3H)_2$  (F. a. T.).—5. With *ethyl iodide* at 100° it yields lophine hydriodide

and *diethylphenium iodide*,  $C_6H_5EtN_3$ , *EtI*; and this latter compound, by treatment with moist silver oxide yields the corresponding base (Kühn, *A.* 132, 326).

**ISOMERISM OF LOPHINE.**—According to Kühn (*A.* 122, 313) an isomeride of lophine,  $C_{10}H_{11}N_3$ , aq., is obtained, together with ordinary lophine, by saturating hydrobenzamide with gaseous HCl, and heating the mixture to 230°. Needles [170°]. v. sol. boiling alcohol. Forms salts.

**AZO-BENZOLIDE**,  $C_{10}H_{11}N_3$  (?) (Laurent, *A. Ch.* [3] 1, 306) and **DIBENZOVOLIMIDE**,  $C_{10}H_{11}NO$  (Robson, *C. J.* 4, 225), are also compounds which are stated to have been obtained by the action of ammonia upon benzoic aldehyde. They have been very little studied.

**BENZOIC ALDEHYDE, HYDROCYANIC ACID, AND AMMONIA.**—A number of compounds are obtained when ammonia acts upon benzoic aldehyde containing hydrocyanic acid. Some of these are, however, more readily prepared from the hydrocyanides of hydrobenzamide (*q. v.*) and have therefore been described under that head.—1. *Benzoylacetide*,  $C_{10}H_{11}N_3$ . Formed along with other products when a mixture of benzoic aldehyde, hydrocyanic acid, and ammonia is allowed to stand for some weeks (Laurent, *A. Ch.* [2] 66, 180; vide *supra*, 'Hydrobenzamide'). Crystalline powder, consisting of minute rhombic prisms, sl. sol. boiling alcohol. By destructive distillation it yields *amarone*,  $C_{10}H_{11}N_3$ , together with lophine and other products. *Amarone* forms colourless needles [233°], sl. sol. boiling alcohol (Laurent, *Revue Scient.* 18, 207).—2. *Azobenzoyl*,  $C_{10}H_{11}N_3$ , is formed according to the equation:

$$3C_6H_5O + HCN + NH_3 = C_{10}H_{11}N_3 + 3H_2O$$

(Beilstein & Reinecke, *A.* 136, 175). White crystalline powder, insol. water, v. sol. ether. When warmed with alcohol and hydrochloric acid it is decomposed into HCN, *amarine*, and a base of the formula  $C_{10}H_{11}N_3$ , which later crystallises in laminae, melting at 122° (Müller & Limpriht, *A.* 111, 140).—3. *Benzhydramide*,  $C_{10}H_{11}N_3O$ , is formed, along with the foregoing, from the same generating substances according to the equation:  $3C_6H_5O + HCN + NH_3 = C_{10}H_{11}N_3O + 2H_2O$ , and differs from it by containing the elements of a molecule of water more. Microscopic crystals. Sl. sol. alcohol, v. sol. ether (Laurent, *A. Ch.* [2] 66, 180; Laurent & Gerhardt, *A.* 76, 302).

**BENZOIC ALDEHYDE, AMMONIA, AND SULPHURATED HYDROGEN.**—1. *Benzoic aldehyde* and ammonium sulphide, if mixed and allowed to stand for some weeks, yield thio-benzaldin

$$3C_6H_5O + 2H_2S + 3H_2 = C_{10}H_{11}NS_2 + 3H_2O$$

(Laurent, *A. Ch.* [3] 1, 291; also [3] 30, 342) Deposited from ether in monoclinic crystals [125°]. When boiled with alcohol it gradually evolves sulphuretted hydrogen.—2. By the action of ammonium sulphide upon crude oil of bitter almonds Laurent obtained a compound  $C_{10}H_{11}N_3S_3$  (?).

Benzoic aldehyde slowly reacts in the cold with  $CS_2$  and  $NH_3$  to form a compound,  $C_{10}H_{11}N_3S_2$  (Quadrat, *A.* 71, 13). The same substance is formed when benzoic aldehyde is mixed with ammonium thio carbamate:  $2C_6H_5O + CS_2 + 2NH_3 = C_{10}H_{11}N_3S_2 + 2H_2O$  (Mül-

der. A. 168, 238). Prismatic crystals, melting with decomposition at 100°. Cannot be dissolved in alcohol or ether without decomposition. The compound may be regarded as, *di-benzylidene - ammonium dithio - carbamate*,  $\text{NH}_4\text{CS}_2\text{N}(\text{CH}_2\text{C}_6\text{H}_5)_2$ . F. R. J.

**BENZOIC ALDEHYDE CARBOXYLIC ACID**  
v. ALDEHYDO-BENZOIC ACID.

**BENZOIC ALDEHYDE GREEN** v. Tetra-METHYL-DIAMIDO-TRIPHENYL-CARBINOL.

**BENZOIC ANHYDRIDE**  $\text{C}_6\text{H}_4\text{O}_2$  i.e.  $(\text{C}_6\text{H}_5\text{CO})_2\text{O}$ . Benzoyl oxide. Mol. w. 226. [42°] (360° i.v.). S.G. (liquid) 22 1.227. H.F. 104,815 (Stolmann, J. pr. [2] 36, 3).

**Formation.**—1. From  $\text{BzCl}$  and  $\text{NaOBz}$ ,  $\text{BaO}$ ,  $\text{H}_2\text{C}_2\text{O}_4$ , or  $\text{K}_2\text{C}_2\text{O}_4$ ; or from  $\text{NaOBz}$  by the action of  $\text{PCl}_5$ ,  $\text{POCl}_3$ , or  $\text{S}_2\text{Cl}_2$  (Gerhardt, A. Ch. [3] 37, 299; Wünder, J. pr. 61, 498; Heintz, P. 92, 458; Gal, A. 128, 127; Anschütz, B. 10, 1882). 2. From benzotrichloride (1 pt.) and  $\text{H}_2\text{SO}_4$  (3 pts. of 95.4 p.c.) (Jensen, B. 12, 1495).—3. By the action of the dry nitrates (6 mols.) of  $\text{Pb}$ ,  $\text{Ag}$ ,  $\text{Hg}$ ,  $\text{Cu}$ , or  $\text{Zn}$  upon benzoyl chloride (1 mol.) (q. v.) (Lachowicz, B. 18, 2990).

**Properties.**—Trimetric prisms, insol. water, m. sol. alcohol and ether. Slowly converted into benzoic acid by boiling water, more rapidly by alkalis. Hot  $\text{NH}_4\text{Aq}$  forms benzamide and ammonium benzoate. Combines with bromine (1 mol.). Gaseous  $\text{HCl}$  forms  $\text{BzCl}$  and  $\text{HOBz}$ .

**Mixed Anhydrides.**—Mixed anhydrides of the form  $\text{BzOR}$  are formed by the action of benzoyl chloride on the alkaline salts of various acids, or by the action of various alkyl chlorides on sodium benzoate. They are generally decomposed by heat into a mixture of two anhydrides; and by water, more rapidly by alkalis, into two acids.

**Benzo-acetic anhydride**  $\text{Ac}_2\text{O.Bz}$  v. ACETO-BENZOIC OXIDE, p. 17.

**Benzo-isovaleric anhydride**

$\text{Bz.O.C}_4\text{H}_9\text{O}$ . Oil (Chiozza, A. 81, 108).

**Benzo-heptioic anhydride**  $\text{Bz.O.C}_6\text{H}_{13}\text{O}$ . Oil. S.G. 1.013 (Chiozza, Malerba, A. 91, 102).

**Benzo-pelargonic anhydride**

$\text{Bz.O.C}_8\text{H}_{17}\text{O}$ . Oil (Chiozza, A. Ch. [3] 89, 209).

**Benzo-myristic anhydride**

$\text{Bz.O.C}_{10}\text{H}_{19}\text{O}$ . [38°].

**Benzo-stearic anhydride**  $\text{Bz.O.C}_{17}\text{H}_{35}\text{O}$ . [70°] (C. a. M.).

**Benzo-angelic anhydride**  $\text{Bz.O.C}_6\text{H}_7\text{O}$ . (C). Oil.

**Benzo-cinnamic anhydride**

$\text{Bz.O.C}_9\text{H}_9\text{O}$ . Ql. S.G. 21 1.184.

**Benzo-cuminic anhydride**

$\text{Bz.O.C}_{11}\text{H}_{19}\text{O}$ . Oil. S.G. 23 1.115.

**BENZOIC BROMIDE** v. BENZOYL BROMIDE.

**BENZOIC CHLORIDE** v. BENZOYL CHLORIDE.

**BENZOIC CYANIDE** v. BENZOYL CYANIDE.

**BENZOICIN** v. Tri-benzoyl-Glycerin.

**BENZOIC OXIDE** v. BENZOIC ANHYDRIDE.

**BENZOIC PEROXIDE** v. BENZOYL PEROXIDE.

**BENZONIN**  $\text{C}_6\text{H}_5\text{O}_2 = \text{C}_6\text{H}_5\text{CH}(\text{OH})\text{CO.C}_6\text{H}_5$ . Phenyl-benzoyl-carbinol. [137°]. First prepared by Stange (Z. P. 16, 93), and almost simultaneously by Robiquet (A. Ch. [2] 21, 254), by acting with a solution of potassium hydroxide or barium hydroxide upon crude oil of bitter almonds containing  $\text{HCN}$ .

**Formation.**—1. By partial oxidation of

hydro-benzoin,  $\text{C}_6\text{H}_5\text{CH}(\text{OH})\text{CH}(\text{OH})\text{C}_6\text{H}_5$  (Zinin, A. 128, 128).—2. By treating benzil  $\text{C}_6\text{H}_5\text{CO.CO.C}_6\text{H}_5$  with zinc and alcoholic hydrochloric acid (Z., A. 119, 177), with acetic acid and iron filings, or with  $\text{K}_2\text{S}$ .

**Preparation.**—200 g. of pure benzoic aldehyde are heated for a short time with a solution of 20 g. of  $\text{KCN}$  in 800 g. of 50 p.c. alcohol, and the liquid allowed to cool. Benzoil separates and is removed by filtration. The filtrate, on heating with more  $\text{KCN}$ , yields a fresh quantity of benzoil (Zincke, A. 198, 151). Two mols. of benzoic aldehyde unite to form 1 mol. of benzoil:  $2\text{C}_6\text{H}_5\text{CHO} = \text{C}_6\text{H}_5\text{CH}(\text{OH})\text{CO.C}_6\text{H}_5$ . The action of the  $\text{KCN}$  is not understood.

**Properties.**—Colourless, lustrous, six-sided prisms. Sl. sol. boiling water. V. sol. hot alcohol; sl. sol. in cold. Conc.  $\text{H}_2\text{SO}_4$  dissolves it with a violet colour.

**Reactions.**—1. Partially decomposed by distillation. Repeated distillation breaks it up for the most part into 2 mols. of benzoic aldehyde; a smaller portion yields benzil and deoxybenzoil:  $2\text{C}_6\text{H}_5\text{O}_2 = \text{C}_6\text{H}_5\text{O}_2 + \text{C}_6\text{H}_5\text{O} + \text{H}_2\text{O}$  (Zinin, B. 6, 1207).—2. Treated in alcoholic solution with zinc and hydrochloric acid it is converted into deoxybenzoil (Zinin, A. 126, 218); at the same time deoxybenzoil-pinacone,  $\text{C}_{12}\text{H}_{22}(\text{OH})_2$ , and hydrobenzoil are formed (Goldenberg, A. 174, 332). Sodium amalgam reduces it to hydrobenzoil. Heating with conc. hydrochloric acid for some hours to 130° converts it into dibenzyl  $\text{C}_{12}\text{H}_{14}$  (Goldenberg). By distillation with zinc-dust it yields stilbene,  $\text{C}_{12}\text{H}_{10}$ , together with an oily hydrocarbon isomeric with stilbene (Jena a. Limpricht, A. 155, 90).—3. Nitric acid oxidises it to benzil (Zinin); but chromic acid, or potassium permanganate, converts it into benzaldehyde and benzoic acid (Zincke, B. 4, 839). It reduces Fehling's solution in the cold, a property common to all compounds containing the group  $\text{CO.CH}(\text{OH})$  (E. Fischer, A. 211, 215).—4. Fusion with caustic potash converts it into benzoic acid with evolution of hydrogen (Liebig a. Wöhler, A. 3, 276). When distilled with soda-lime, the benzoate which is first formed is decomposed by the excess of soda-lime, and benzene is obtained (Jena a. Limpricht). The action of alcoholic potash is complex: when benzoil and alcoholic potash are heated with access of air, benzoic acid, a small quantity of benzoic acid ( $\text{C}_6\text{H}_5\text{O}_2$ ), benzoil ether ( $\text{C}_6\text{H}_5\text{O}_2$ , [157°]), and a compound  $\text{C}_{12}\text{H}_{14}\text{O}$  (to which Limpricht a. Schwanert gave the name ethyl-dibenzoil, assigning to it the formula  $\text{C}_{10}\text{H}_{12}\text{O}_2$ ) are formed—this last, however, is produced from benzil generated by the air-oxidation of the benzoil (v. BENZIL). If the benzoil is heated with alcoholic potash in a sealed tube at 100° the products are benzoic acid, hydrobenzoil, and ethylbenzoic acid ( $\text{C}_6\text{H}_5\text{O}_2$ ). With very concentrated alcoholic potash at 160° benzoil yields benzoic acid, stilbene, a compound  $\text{C}_{12}\text{H}_{12}\text{O}_2$ , and a small quantity of ethyl-benzoic acid. By heating benzoil with a solution of sodium ethylate in alcohol, ethyl-benzoil,  $\text{C}_{12}\text{H}_{14}\text{O}_2\text{C}_2\text{H}_5$ , [95°], is formed, together with the various products already mentioned. Prisms, with a vitreous lustre, v. sol. alcohol (Jena a. Limpricht, A. 155, 89; Limpricht a. Schwanert, B. 4, 336; Japp a. Owens, C. J. 47, 90).—5. Chlorine acts like nitric acid, con-

verting benzoin into benzil (Laurent, *A. Ch.* [2] 59, 401).—6. When heated with fuming hydrochloric acid at 130° for 6 or 8 hours it yields lepidene,  $C_{10}H_{16}O$  (g. v.), benzil, and a thick yellow oil (Zinin, *J. pr.* 101, 160).—7. When boiled with dilute sulphuric acid it parts with the elements of water, yielding oxylepidene:  $-2C_{10}H_{16}O_2 = C_{10}H_{16}O + 2H_2O$  (Limpriecht a. Schwanert, *B.* 4, 335). Concentrated sulphuric acid converts it into benzil (Zinin).—8. Heated with alcoholic ammonia for some hours at 100° in sealed tubes it yields benzoinam,  $C_{10}H_{11}N$  (silky needles, v. sl. sol. alcohol, melting with decomposition), benzoinidam,  $C_{10}H_{11}NO$ ? [199°] (granular crystals, sl. sol. alcohol), and tetra-

$C_6H_5.C-N-C.C_6H_5$  [246°], to phenyl-azine,  $C_6H_5.C-N-C.C_6H_5$  [246°], together with some lophine,  $C_{10}H_{16}N_2$ . Tetra-

phenyl-azine is best prepared by heating benzoin with ammonium acetate until the salt is volatilised, dissolving the product in the strongest alcoholic hydrochloric acid, and ppg. with alcohol. V. sl. sol. alcohol, v. sol. alcoholic hydrochloric acid, v. sol. boiling benzene, sol. with blood-red colour in cold conc.  $H_2SO_4$ . Sublimes without decomposition. Heating with soda-lime converts it into tetraphenylene-azine  $C_{18}H_{12}N_2$  (Laurent, *A. Ch.* [2] 66, 181; Erdmann, *A.* 135, 181; Japp a. Wilson, *C. J.* 1886, 825; Japp a. Burton, *C. J.* 1886, 843; 1887, 98).—9. Benzoin reacts with the primary amines of the benzoinoid series, when heated with them to 200°, eliminating 1 mol. of water and generating feebly basic compounds which by boiling with acids are decomposed into their generating substances. Anilbenzoin  $C_{15}H_{13}CH(OH).C(NC_6H_5)_2$  [99°], from aniline and benzoin, forms yellowish needles, v. sol. most organic menstria. Yields with nitrous acid nitroso-anilbenzoin  $C_{15}H_{13}CH(OH).C(NC_6H_5).NO$  [140°], with acetic anhydride a monoacetyl-derivative [153°], and with bromine a monobromo-derivative [168°]. Sodium amalgam reduces anilbenzoin in alcoholic solution to hydrobenzoin-anilide  $C_{15}H_{13}CH(OH).CH(NH.C_6H_5)_2$  [119°], which forms with sulphuric acid a salt not decomposed by boiling with the dilute acid.—*p-Tolilbenzoin*  $C_{15}H_{13}CH(OH).C(NC_6H_4.CH_3)_2$  [144°] resembles in its properties and its behaviour towards reagents the aniline compound. It yields with nitric acid a mono-nitro-derivative [125°] and a di-nitro-derivative [195°].—*β-Naphthilbenzoin* [130°] also resembles the aniline compound (Voigt, *J. pr.* 31, 1).—10. Benzoin reacts with hydroxylamine and with phenyl-hydrazine.—Benzoin-ozim,  $C_{15}H_{13}CH(OH).C(N.OH).C_6H_5$  [151°–152°]. An alcoholic solution of benzoin is mixed with an aqueous solution of hydroxylamine and allowed to stand for a week. Microscopic prisms, soluble in benzene (Wittenberg a. V. Meyer, *B.* 16, 504).—Benzoin-phenylhydrazide,  $C_{15}H_{13}CH(OH).C(NH.C_6H_5)_2$  [155°]. Benzoin and phenylhydrazine, together with a little alcohol, are heated at 100°. Needles, sol. benzene (Pickel, *A.* 232, 229).—11. By heating with *acetyl-chlorides* the hydroxylic hydrogen of benzoin may be replaced by acid radicals to form ethereal salts. Benzoin acetate,  $C_{17}H_{15}(C_2H_3O)_2$  [75°].

From benzoin and acetyl chloride. Monoclinic prisms or tables, v. sol. ether and alcohol (Zinin, *A.* 104, 120; Jena a. Limpriecht, *A.* 155, 92).—Benzoin benzoate,  $C_{17}H_{15}(C_6H_5O)_2$  [125°]. By warming benzoin with benzoyl chloride. Slender needles. Sol. hot alcohol. Yields a mono-nitro-compound [137°] (Zinin).—Benzoin succinate,  $(C_{17}H_{15}O_2)_2.C_4H_4O_4$  [129°]. By heating benzoin with succinyl chloride to 100°. Leaflets from alcohol. Sol. also in ether and  $CS_2$  (Lukanin, *B.* 5, 331).—12. When benzoin is heated with hydrocyanic acid and alcohol to 200° the process of its formation is reversed and it is broken up into benzoic aldehyde. A part of the benzoic aldehyde undergoes a further change, yielding amongst other products ethylic benzoate (Michael a. Palmer, *Am. J.* 192). 13. Phenyl cyanate forms  $Ph.CH(O.CO.NHPh).CO.Ph$  [163°] (Gumpert, *J. pr.* 2, 32, 280). F. R. J.

**BENZOIN, GUM.** A resin which flows from the bark of *Styrax benzoin*, a tree growing in Sumatra, Borneo, Java, and Siam. Gum benzoin contains, besides various resins, benzoic acid and, frequently, cinnamic acid. Siamese and Palembang benzoin are free from cinnamic acid. Potash fusion produces benzoic, *p*-oxybenzoic, and protocatechuic acids, and pyrocatechin. Distillation with zinc-dust gives toluene and a little *o*-xylene, naphthalene, and methyl-naphthalene.

*References.*—Unverdorben, *P.* 8, 397; Van der Vliet, *A.* 34, 177; Kopp, *C. R.* 19, 1269; Kolbe a. Lautenmann, *A.* 115, 113; 119, 136; Deville, *A. Ch.* [3] 3, 192; Ashoff, *J.* 1861, 400; Wiesner, *J.* 1872, 1060; Thecgarten, *J.* 1874, 922; Giannicani, *B.* 11, 274; Saalfeld, *A. Ch.* [3] 16, 280.

#### BENZOIN DI-*p*-CARBOXYLIC ACID

$C_{18}H_{12}O_6$ ,  $C_6H_5(CO_2H).CH(OH).CO_2C_6H_5$ . Formed by oxidation of di-*p*-aldehydo-benzoin with  $KMnO_4$ . Short felted needles. Sublimable. Infusible.  $Ag.A^{+}$ . Di-methyl ether  $Me.A^{+}$  [126°] (Oppenheimer, *B.* 19, 1816).

**BENZOLEIC ACID**  $C_{11}H_{10}O_2$  Hydrobenzoic acid. Formed, together with benzyl alcohol, by the action of sodium amalgam on an aqueous solution of benzoic acid kept acid by  $HCl$  (Hermann, *A.* 132, 75; Otto, *A.* 134, 303). Oil, smelling of valeric acid, heavier than water, v. sol. alcohol and ether.— $EtA^{+}$  oil.

**BENZOLINE.** A mixture of paraffins (hexane, heptane, octane) boiling between 70° and 100° obtained by distilling petroleum or paraffin oil. The mixture is also called petroleum spirit or ligroin.

**BENZOLON.** Identical with lophine (v. BENZIL).

**BENZODIMETHYLANILINE** v. DIMETHYL-AMINO-BENZOPHENONE.

*m*-BENZO-DI-METHYL-DI-FURFURANE,  $C_{12}H_{10}O_2$  i.e.

[e. 27°]. (270° at 720 mm.). Obtained by evaporating (β)-benzo-di-methyl-di-furfurane-di-carboxylic ether  $C_6H_4(<\begin{array}{c} CMe \\ | \\ O \end{array}>C.CO_2Et)_2$  with alcoholic KOH and lime, and dry distillation. Prisms. By warming with conc.  $H_2SO_4$ , a pure

blue colouration is produced (Hantzsch, B. 19, 2933; 20, 1337).

*p*-Benzo-di-methyl-di-furfurane

$C_6H_4(\text{CMe}_2\text{CH})_2$ . [108°]. Obtained\* by heating the potassium salt of the di-carboxylic acid with lime. Large pearly tables with bluish fluorescence. V. sol. alcohol, ether, etc. (Nuth, B. 20, 1337).

Benzo-tri-methyl-tri-furfurane  $C_{15}H_{12}O_6$  i.e.

$C_6(\text{CMe}_2\text{CH})_3$ . [115°-120°]. Needles.

Very soluble in ordinary solvents. Formed by evaporating the tri-carboxylic ether

$C_6(\text{CMe}_2\text{C.CO}_2\text{Et})_3$ , with alcoholic KOH and lime, and dry distillation (Lang, B. 19, 2936).

*o*-BENZO-DI-METHYL-DI-FURFURANE DI-CARBOXYLIC ACID

$C_6H_4(\text{CMe}_2\text{C.CO}_2\text{H})_2$ . Obtained by saponification of the ethyl-ether which is formed by dissolving in conc.  $H_2SO_4$  the product of the action of chloro-acetacetic ether (2 mols.) upon di-sodium pyroacetelchin (1 mol.). Amorphous solid.—BaA" 2aq.

*Di-ethyl ether* Et<sub>2</sub>A": [155°]; short prisms (from alcohol), or long white needles (from ether) (Nuth, B. 20, 1337).

(a)-*m*-Benzo-di-methyl-di-furfurane di-carboxylic acid  $C_{11}H_{10}O_6$  i.e.

$HO_2C.C_6(\text{CMe}_2\text{C})_2.C_6H_4(\text{CMe}_2\text{C})_2.CO_2H$ . [Far

above 810°]. Formed by saponification of the di-ethyl-ether. This ether is obtained, together with a much larger quantity of the (β)-isomeride by the action of chloro-acetacetic ether upon di-sodium resorcin  $C_6H_4(ONa)_2$  in presence of alcohol, extracting with benzene, dissolving the undissolved portion in conc.  $H_2SO_4$ , pouring into water, and extracting with ether; when the ethereal solution is mixed with hot alcohol and allowed to cool the (a)-ether crystallises out, whilst the (β)-ether remains in solution. The two ethers are also formed (the a in very small quantity) by heating oxy-methyl-coumarilic ether

$C_6H_4(OH)(\text{CMe}_2\text{C})_2.CO_2Et$  with chloro-aceto-

acetic ether and alcoholic NaOEt, and dissolving the product in  $H_2SO_4$ . The acid is a white microcrystalline solid. Scarcely soluble in water, more readily in alcohol. The salts of the heavy metals are all sparingly soluble. Warm  $H_2SO_4$  produces a pure blue colouration.

*Di-ethyl ether* Et<sub>2</sub>A": [186°]; needles; sl. sol. alcohol (Hantzsch, B. 19, 2930).

(β)-*m*-Benzo-di-methyl-di-furfurane-di-carboxylic acid  $C_{11}H_{10}O_6$  i.e.

$HO_2C.C_6(\text{CMe}_2\text{C})_2.C_6H_4(\text{CMe}_2\text{C})_2.CO_2H$ . [Far

above 810°]. Formed by saponification of its di-ethyl ether. Microcrystalline solid. Scarcely soluble in water, more easily in alcohol. Gives sparingly soluble pps. with the salts of the heavy metals. The acid and its ether give a pure blue colouration with warm  $H_2SO_4$ .

*Di-ethyl ether* Et<sub>2</sub>A": [141°]; small white needles; more soluble than the (β)-isomeride. Formed, together with a small quantity of the (β)-ether, by the action of chloro-acetacetic ether upon dry di-sodium resorcin, extraction with benzene, dissolving the residuo in conc.  $H_2SO_4$ , pouring into water, and extracting with ether. Also by heating oxy-methyl-coumarilic ether

$C_6H_4(OH)(\text{CMe}_2\text{C})_2.CO_2Et$  with chloro-acetacetic

ether and alcoholic NaOEt, and dissolving the product in  $H_2SO_4$ . By evaporation with alcoholic KOH and lime and dry distillation it yields (β)-benzo-di-methyl-di-furfurane

$C_6H_4(\text{CMe}_2\text{CH})_2$ . (Hantzsch, B. 19, 2930).

*p*-Benzo-di-methyl-di-furfurane-di-carboxylic acid  $C_6H_4(\text{CMe}_2\text{C.CO}_2H)_2$ . Obtained by

saponification of its ethyl-ether which is formed by dissolving in conc.  $H_2SO_4$  the product of the action of chloro-acetacetic ether (2 mols.) upon di-sodium hydroquinone (1 mol.). Amorphous solid (containing aq).

Salts.—Ag.A": white pp.—BaA" 2aq: sl. sol. yellowish-white powder.

*Ethyl ether* Et<sub>2</sub>A": [150°]; glistening greenish plates; v. sl. sol. all solvents (Nuth, B. 20, 1331).

Benzo-tri-methyl-tri-furfurane-tri-carboxylic acid  $C_{15}H_{12}O_9$  i.e.  $C_6(\text{CMe}_2\text{C.CO}_2H)_3$ .

Formed by saponification of its ethyl ether which is obtained by treating dry powdered tri-sodium-phloroglucol (1 mol.) with chloro-acetacetic ether (3 mols.), dissolving the product in  $H_2SO_4$ , and pouring into water. Gelatinous pp. (containing aq). Scarcely soluble in alcohol and ether. Its salts are mostly insoluble and gelatinous. Ba.A" 7aq: microcrystalline.

*Ethyl ether* Et<sub>2</sub>A": [c. 298°]; small white glistening needles; sl. sol. all solvents, most readily in chloroform (Lang, B. 19, 2935).

BENZONAPHTHONE c. NAPHTHOQUINONE.

BENZONAPHTHYL-THIAMIDE c. Thiobenzo-yl-(a)-NAPHTHYLAMINE.

BENZONITRILE  $C_6H_5N$  i.e.  $C_6H_5.CN$ . Mol. w. 103. [−17°] (Hofmann). (190-5°). S.G. 2 1.023;  $d_4^{20}$  1.008 (Kopp, A. 98, 373). S. 1 at 100°. S.V. 123-7 (Ramsay).

*Formation*.—1. By the dry distillation of ammonium benzoate (Fehling, A. 49, 91).—2. From benzamide by heating it alone or with CaO (Anschütz a. Schultz, A. 196, 48), BaO (Wöhler, A. 192, 362),  $P_2O_5$  (Hofmann a. Buckton, A. 100, 155),  $PCl_5$  (Hencke, A. 106, 276), or  $P_2S_5$  (Henry, A. 2, 307).—3. By heating hippuric acid alone (Limpricht a. Usler, A. 89, 133), or with  $ZnCl_2$  (Gössmann, A. 100, 74).—4. By the action of  $BzCl$  or  $Bz_2O$  on benzamide.—5. By the action of  $BzCl$  on oxamide, on potassium sulphocyanide (Limpricht, A. 99, 117), or on potassium cyanate (Schiff, A. 101, 93).—6. By heating  $Bz_2O$  with potassium cyanate or sulphocyanide.—7. By the action of  $HgO$  on thiobenzamide.—8. By heating benzoic acid with sulphocyanide of lead (Krüss, B. 17, 1787), or of potassium (Letts, B. 5, 678).—9. From potassium benzoate and cyanogen bromide (Hantzsch, B. 19, 2930).

**4. Ca.** [3] 52, 260).—10. By distilling a mixture of aniline and oxalic acid (Hofmann, C. R. 64, 388).—11. Formed by distilling formamide over zinc-dust; the yield is nearly 20 p.c. of the formamide (Gasiorowski a. Merz, B. 17, 78; B. 18, 1001).—12. Formed together with sodium formate, by the action of dilute NaOH upon aniline di-chloro-acetate (Cech a. Schwebel, C. C. 1877, 134).—13. Formed by running an aqueous solution of diazobenzene chloride into a hot solution of  $\text{Cu}_2(\text{CN})_2$  (Sandmeyer, B. 17, 2653).—14. By heating tri-phenyl phosphate with potassium cyanide or ferrocyanide; the yield is 25 p.c. of the theoretical (Scruggam, A. 92, 318; Heim, B. 16, 1771).—15. By heating potassium benzene sulphonate with KCN (Merz, Z. 1868, 83).—16. From  $\text{KFeCy}_2$  and chloro- or bromobenzene at  $400^\circ$  (Merz a. Weith, B. 8, 918; 10, 749).—17. From iodo-benzene and  $\text{AgCy}$  (Merz a. Soehnleberger, B. 8, 1630).—18. Together with terephthalonitrile, by passing a mixture of benzene and cyanogen through a red-hot tube (M. a. S.).—19. By passing dimethylaniline through a red-hot tube (Nietzki, B. 10, 474).—20. By the action of  $\text{C}_2\text{Cl}_4$  on benzene in presence of aluminium chloride (Friedel a. Crafts, Bl. [2] 24, 2).—21. From bromo-benzene,  $\text{CyCl}_3$ , and Na (Klason, J. pr. [2] 35, 83).—22. By boiling phenyl thiocarbimide with finely divided Cu.—23. From phenyl carbamine by intramolecular change at  $240^\circ$  (Weith, B. 6, 213).—24. By the action of acetic anhydride on benzaldoxim (Lach, B. 17, 1571).

**Properties.**—Colourless oil, smelling of almonds; sinks in cold, but swims in hot water; miscible with alcohol and ether.

**Reactions.**—1. Cold aqueous potash has no action, but on boiling it forms  $\text{NH}_3$  and  $\text{KOBz}$ ; dilute acids act similarly.—2. Heating with potassium gives  $\text{KC}_2$ , cyaphenine,  $(\text{C}_6\text{H}_5)_2\text{C}_2$ , and other bodies (Bingley, Chem. Gaz. 1854, 329; Hofmann, B. 1, 198). When the boiling alcoholic solution is treated with sodium, the greater part is saponified whilst a smaller portion undergoes reduction to benzylamine and to benzene (Bamberger a. Lodter, B. 20, 1709).—3.  $\text{H}_2\text{S}$  or ammonium sulphide forms thiobenzamide.—4. Zn and HCl in alcoholic solution form mono-, di-, and tri-benzylamine (Mendius, A. 121, 129; Spica, G. 10, 515).—5. Fuming  $\text{H}_2\text{SO}_4$  forms, on heating, benzene sulphonic acid; at  $20^\circ$  it forms cyaphenine. Benzonitrile (10g.) cooled with ice and treated with fuming  $\text{H}_2\text{SO}_4$  (7 g.) added slowly, forms dibenzamide  $\text{NHBz}_2$  (148°), and 'benzimidobenzamide'  $\text{NHBz.C(NH).C}_6\text{H}_5$  (106°), called by Pinner a. Klein 'benzimidobenzozate' and 'dibenzimidobenzoxide', respectively. Dilute HCl converts the former into the latter (F. Gumpert, J. pr. [2] 30, 87; Pinner, *ibid.*, 125).—6. Boiled with zinc ethyl it gives off ethane (1 vol.) and an olefine (1 vol.) and forms a product, whence, by treatment first with alcohol, and then with aqueous HCl, cyaphenine (q.v.) and the hydrochloride of a base which crystallises in six-sided plates,  $\text{C}_6\text{H}_5\text{N}_2\text{Cl}$ , is formed. This body (237°) is readily soluble in alcohol, but sparingly so in water. Potash liberates the base as a colourless oil (Frankland a. Evans, C. J. 37, 565).—7. By exhaustive chlorination with  $\text{SbCl}_5$  yields penta-chloro-cyano-benzene  $\text{C}_6\text{Cl}_5\text{CN}$

(Merz a. Weith, B. 16, 2885).—8. With methylal and  $\text{H}_2\text{SO}_4$ , it gives the benzoyl derivative of methylene diamine (q.v.).—9. With diphenylamine hydrochloride at  $180^\circ$  it forms di-phenylbenzamidine; but at  $240^\circ$  it forms a Base  $\text{C}_{12}\text{H}_{13}\text{N}$  (183°), thus:  $\text{C}_6\text{H}_5\text{C(NH)N(C}_6\text{H}_5)_2 = \text{NH}_2 + \text{C}_{12}\text{H}_{13}\text{N}$ . **Properties.**—Thick prisms (from benzene), containing benzene of crystallisation; yellow tablets (occasionally from benzene); long thin prisms (from alcohol). The tablets are monoclinic,  $a:b:c = 5875:1:5014$ ,  $L = 51^\circ 23'$  (Bodewig). Soluble in benzene and ether, slightly in alcohol. Its alcoholic solution is neutral. Acetyl chloride does not act on it. Salts:  $\text{B}^+\text{HCl}$ . Narrow red prisms. [Above  $220^\circ$ ].—( $\text{B}^+\text{HCl}$ ). $\text{PtCl}_4$ .

**Combinations.**—1. With metallic chlorides. —  $(\text{C}_6\text{H}_5\text{N})_2\text{AuCl}_2$ . —  $(\text{C}_6\text{H}_5\text{N})_2\text{PtCl}_4$ . —  $(\text{C}_6\text{H}_5\text{N})_2\text{SnCl}_4$ . —  $(\text{C}_6\text{H}_5\text{N})_2\text{TiCl}_4$  (Henke, A. 106, 284).—2. With halogens.  $\text{C}_6\text{H}_5\text{CBr:NBr}$ . —  $(\text{C}_6\text{H}_5\text{CN})_2\text{Br}_2$ ; needles (Engler, A. 133, 137).—3. With hydrogen chloride:  $\text{C}_6\text{H}_5\text{N}_2\text{HCl}$  (Pinner a. Klein, B. 10, 1891; cf. Gerhardt, Traité, 4, 762). — 4. With hydrogen bromide.  $\text{C}_6\text{H}_5\text{N}_2\text{HBr}$  (70°) (Engler, A. 149, 307). — 5. With alcohols. — Benzimidobenzyl ether,  $\text{C}_6\text{H}_5\text{C(OC}_6\text{H}_5)_2\text{NH}$ . The hydrochloride,  $\text{B}^+\text{HCl}$ , is formed by passing dry HCl gas into a mixture of ethyl alcohol and benzonitrile, diluted with ether. Large glistening prisms; decomposes on heating to about  $120^\circ$  into ethyl chloride and benzamide (Pinner, B. 16, 1654). Benzimidobenzyl isobutyl ether  $\text{C}_6\text{H}_5\text{C(OC}_4\text{H}_9)_2\text{NH}$ . The hydrochloride  $\text{B}^+\text{HCl}$  is formed by passing HCl into a cooled mixture of benzonitrile and isobutyl alcohol (Pinner a. Klein, B. 10, 1890); it gradually loses HCl becoming  $\text{B}^+\text{HCl}$  (135°). —  $\text{B}^+\text{HCl.PtCl}_4$ . —  $\text{B}^+\text{HCl}$ . — 6. With acids. — Benzimidobenzyl acetate  $\text{C}_6\text{H}_5\text{C(OAc)}_2\text{NH}$  (116°). From benzimidobenzyl ether and  $\text{Ac}_2\text{O}$  (Pinner a. Klein, B. 11, 9). — 7. With mercaptans. — Benzimidobenzyl thio-ether  $\text{C}_6\text{H}_5\text{C(SEt)}_2\text{NH}$ . From benzonitrile, mercaptan, and HCl, or from thiobenzamide and EtI (Bernthsen, A. 197, 848). Oil; decomposes readily into mercaptan and benzonitrile. —  $\text{B}^+\text{HCl}$  (188°). —  $\text{B}^+\text{HCl.PtCl}_4$ . —  $\text{B}^+\text{HCl}$  (142°). Benzimidobenzyl isocamyl thio-ether  $\text{C}_6\text{H}_5\text{C(SC}_6\text{H}_{13})_2\text{NH}$ . The hydrochloride,  $\text{B}^+\text{HCl}$ , is formed by passing HCl into a mixture of benzonitrile and isocamyl mercaptan (Pinner a. Klein, B. 11, 1825). The free base is an oil. Benzimidobenzyl thio-ether  $\text{C}_6\text{H}_5\text{C(SC}_6\text{H}_5)_2\text{NH}$ . Prepared like the ethyl ether. —  $\text{B}^+\text{HCl}$  (181°).

**Derivatives of Benzonitrile** are described as Bromo-, Nitro- &c. BENZONITRILE.

#### BENZO-PHENOL v. OXY-BENZOPHENONE.

**BENZOPHENONE**  $\text{C}_{12}\text{H}_{10}\text{O}$  i.e.  $\text{C}_6\text{H}_5\text{CO.C}_6\text{H}_5$ . Di-phenyl-ketone. Mol. w. 182. [48°]. (805° i.v.).

**Formation.**—By the dry distillation of calcium benzoate (Peligot, A. 12, 41; Chancel, A. 72, 279).—2. From  $\text{BzCl}$  and  $\text{HgPh}_2$  (Otto, B. 8, 197).—3. From  $\text{BzCl}$  and benzene in presence of  $\text{AlCl}_3$ .—4. From benzoic acid, benzene, and  $\text{P}_2\text{O}_5$  at  $190^\circ$  (Kollarits a. Merz, B. 6, 446, 538).—5. From benzene,  $\text{COCl}_2$ , and  $\text{AlCl}_3$  (Friedel, Crafts, a. Ador, C. R. 85, 873).—6. By oxidation of di-phenyl-methane (Zincke, A. 159, 877).

**Preparation.**—From  $\text{BzCl}$ ,  $\text{C}_6\text{H}_6$ , and  $\text{AlCl}_3$ .

the yield is 70 p.c. of the calculated (Elbs, *J. pr.* [2] 85, 465).

**Properties.**—Prisms; insol. water, v. sol. alcohol and ether.

**Reactions.**—1. Reduced by HI to di-phenyl-methane (Graebe, *B. 7*, 1624).—2. Reduced by zinc-dust to di-phenyl-methane, tetra-phenyl-ethylene, and tetra-phenyl-ethane (Staedel, *A.* 194, 307).—3. Potash-fusion gives benzoic acid and benzene.—4. Reduced to di-phenyl-carbinol by sodium-amalgam or by heating with alcoholic potash.—5. Ammonia has no action.—6. Zn and alcoholic  $H_2SO_4$  reduce it to benzpinacolone and (a) and (b)-benzpinacolin (Zincke a. Thörner, *B. 11*, 1396).—7. AcCl in presence of zinc-dust acts on an ethereal solution forming crystalline (a) and (b)-benzpinacolin.—8.  $PCl_5$  forms di-chloro-di-phenyl-methane.—9. Passage through a red-hot tube slightly decomposes it; the product contains benzene, di-phenyl, and *p*-di-phenyl-benzene, while gaseous carbonic oxide, hydrogen, and acetylene escape (Barbier a. Roux, *C. R.* 102, 1559).—10. When heated with ammonium formate at  $200^\circ$ – $220^\circ$  it yields the formyl derivative of di-phenyl-carbinyl-amine ( $C_6H_5$ )<sub>2</sub>CH.NH.CHO (Leuchart a. Bach, *B.* 19, 2129).—11.  $P_2S_5$  at  $100^\circ$  forms  $C_{12}H_{10}S_2$  [153], crystallising in lustrous flat monoclinic needles. At  $200^\circ$  it turns deep blue (Japp a. Rusehen, *C. J.* 49, 481).—12.  $P_2S_5$  at  $140^\circ$  forms  $C_{12}H_{10}P_2S_5$  [227], crystallising in minute plates, insol. alcohol, sl. sol. hot benzene. On melting it turns deep blue. It is oxidised by  $CrO_3$  in  $HOAc$  to benzophenone (J. a. R.).

**Oxim** ( $C_{13}H_{11}NO$ ). *Di-phenyl-ketoxim*. [ $140^\circ$ ]. Prepared by boiling an alcoholic solution of benzophenone (30g.) with hydroxylamine hydrochloride (24g.) and a little HCl for a day (Beckmann, *B.* 19, 988; Janny, *B.* 16, 2782). Silky needles, v. sol. ether and acetone, m. sol. benzene and ligroin, v. sl. sol. cold water. Sol. acids and alkalis. Resolved by acids into its constituents. By  $PCl_5$  or  $POCl_3$  it is converted into  $\alpha$ -chloro-benzylidene-aniline,  $C_6H_5.N:CCl.C_6H_5$ , produced by intramolecular change from  $(C_6H_5)_2C:NCl$  (B.). By warming with conc.  $H_2SO_4$  to  $100^\circ$  it is converted by similar isomeric change into benzanilide (Beckmann, *B.* 20, 1507). Salts.— $C_{13}H_{10}N(OH).Cl$ : crystalline powder.— $C_{13}H_{10}N(OH).HCl$ : white powder.

**Methyl-oxim**  $C_{13}H_{13}N(OMe)$ : [ $92^\circ$ ]; yellow crystals.

**Ethyl-oxim**  $C_{15}H_{15}N(OEt)$ : ( $276^\circ$ – $279^\circ$ ); fluid.

**Benzyl-oxim**  $C_{15}H_{15}N(OC_6H_5)$ : [ $56^\circ$ ]; white crystals.

**Acetyl oxim**  $C_{15}H_{15}N(OAc)$ : [ $55^\circ$ ]; white crystals (Spiegler, *B.* 17, 810; *M.* 6, 203).

**Phenyl hydrazide**  $Ph.C_6H_4.NHPh$ . [ $137^\circ$ ]. Got by boiling benzophenone with phenyl hydrazine and alcohol; or by heating the oxim with phenyl-hydrazine,  $N_2$  and  $NH_3$  being evolved. Needles (from alcohol). Insoluble in water, not very soluble in alcohol. Heated for some time with dilute (20 p.c.) HCl, it is resolved into benzophenone and phenyl hydrazine (Pickel, *A.* 232, 228; Fischer, *B.* 17, 576; Just, *B.* 19, 1206).

**Isomeride of Benzophenone**. [ $26^\circ$ ]. ( $305^\circ$ ). Sometimes formed in oxidising di-phenyl-methane or in distilling calcium acetate with

calcium benzoate (Zincke, *A.* 159, 887). Readily changes into ordinary benzophenone.

**Derivatives of benzophenone** are described as AMIDO-, BROMO-, CHLORO-, CYANO-, NITRO-, OXY-, &c., BENZOPHENONE, and as DI-PHENYLENE-KETONE OXIDE.

**BENZOPHENONE-CARBOXYLIC ACID** v. BENZOYL-BENZOIC ACID.

**BENZOPHENONE-DI-*p*-CARBOXYLIC ACID** [ $4:1$ ]  $C_6H_4(CO_2H).CO.C_6H_4(CO_2H)$  [ $1:4$ ]. Formed by boiling di-*p*-cyano-benzophenone with alcoholic KOH (Brümme, *B.* 20, 522). Also by the oxidation of di-tolyl-methane, or di-methyl-benzophenone, with chromic mixture (Weiler, *B.* 7, 1185; Ador a. Crafts, *B.* 10, 2173). Microscopic needles. Sublimes at a high temperature without melting. Sl. sol. alcohol, benzene, and ether. S. (hot water) = 0.02. The  $NH_4$  salt gives pps. with salts of Fe, Co, Cu, Ba, and Ca, but not with salts of Pb, Cr, Zn, Mg, and Ni. Silver salt  $A''Ag_2$ ,  $Ag_2O$ : insol. water.

*Di-methyl ether*  $A''Me_2$ : [ $138^\circ$ ]; large needles (B.).  $Ag_2A'$  (A. a. C.).

**Benzophenone dicarboxylic acid**

$C_6H_5.CO.C_6H_4(CO_2H)_2$ .

*Benzoyl-isophthalic acid*: [ $280^\circ$ ]. From benzyl-isoxylene and chromic mixture (Zincke, *B.* 9, 1762). Sl. sol. hot water and  $CHCl_3$ , v. sol. alcohol. Converted by Zn and HCl into the lactone of  $C_6H_5.C(OH)(C_6H_5)(CO_2H)_2$ —Salts:  $CaA''aq.$ — $BaA''aq.$ — $Ag_2A''$ .

*Methyl ether*  $Me_2A''$ : [ $118^\circ$ ].

*Ethyl ether*  $Et_2A''$ : [ $95^\circ$ ].

**Benzophenone dicarboxylic acid**

$C_6H_5.CO.C_6H_4(CO_2H)_2$ . [ $1:2:5$ ].

*Benzoyl-terephthalic acid*. ( $290^\circ$ ) (W.); [ $285^\circ$ ] (F.).

**Formation.**—1. By oxidising benzyl-cymene with chromic mixture (Weber, *J.* 1878, 402).—2. From benzoyl-*p*-xylene and  $HNO_3$  (S. G. 1-18) at  $170^\circ$  (Elbs, *J. pr.* [2] 35, 479).—3. From phenyl *p*-cymyl ketone and dilute  $HNO_3$ .

**Properties.**—V. sl. sol. water, v. sol. alcohol. Reduced by Zn and HCl to

$C_6H_5.CH(OH).C_6H_4(CO_2H)_2$ — $CaA''$  aq.— $BaA''$  5aq.— $Ag_2A''$ .

*Methyl ether*  $Me_2A''$ : [ $101^\circ$ ]; needles.

*Ethyl ether*  $Et_2A''$ : [ $101^\circ$ ]; prisms.

**Benzophenone tetra-carboxylic acid**

$C_6H_5.CO.C_6H_4(CO_2H)_4$ . From benzoyl-iso-durene and  $KMnO_4$  (Essner a. Gossin, *Bl.* [2] 42, 170).

**BENZOPHENONE CHLORIDE** is *exo*-DI-CHLORO-DI-PHENYL-METHANE (*q. v.*).

**BENZOPHENONE OXIDE** v. DI-PHENYLENE-KETONE OXIDE.

**BENZOPHENONE SULPHONE**  $C_{13}H_9SO_2$ , i.e.

$SO_2 \langle C_6H_4 \rangle CO$ . [ $187^\circ$ ]. From benzophenone and fuming  $H_2SO_4$  (Beckmann, *B.* 6, 1112; 8, 992). V. sol. ether, sol. alkalis; converted by water at  $190^\circ$  into an isomeride (?) [ $175^\circ$ ].

**BENZOPHENONE DI-SULPHONIC ACID**  $C_{13}H_9(SO_3H)_4O$ . From benzophenone and fuming  $H_2SO_4$  by warming (Staedel, *A.* 194, 314). Converted by potash fusion into phenol and *p*-oxy-benzoic acid.— $BaA''$ .

**Chloride**  $CO(C_6H_5SO_2Cl)_2$ . [ $122^\circ$ ] (Beckmann, *B.* 8, 992).

**BENZOPHENYL- v. BENZOYL-PHENYL-**

**BENZOPHENONIC ACID** is CARBOXY-BENZENE PROPIONIC ACID (q. v.).

**BENZOPINACOLIN** is BENZPINACOLIN (q. v.).

**BENZOPINACONE** is BENZPINACONE (q. v.).

**BENZOQUINOL** is HYDROQUINONE (q. v.).

**BENZOQUINONE** is QUINONE (q. v.).

**BENZORESORCIN** v. DIOXYBENZOTRINONE.

**DI-BENZO-RESORCIN** v. DI-*o*-PHENYLENE-DI-PHENYL-DI-RETONE.

**BENZOSTILBINE** is IOPHINE (v. p. 474).

**BENZO-SUCCINIC ACID** v. BENZOYL-SUCCINIC ACID.

**BENZOTHIAMIDE** v. THIO-BENZAMIDE.

**BENZO-TOLUIDINE** v. PHENYL AMIDO-TOLYL KETONE.

**BENZOTROPEINE** v. BENZOYL-TROPEINE.

**BENZOXAMIDINE** v. BENZAMIDOXIM.

**BENZ-OXIMIDO-AMIDE** v. BENZAMID-OXIM.

**BENZ-OXIMIDO-ETHYL-ETHER**

$C_6H_5NO$ , i.e.  $C_6H_5CO(OEt)NOH$ . Formed by the action of hydroxylamine hydrochloride on benz-imido-ether (v. BENZOSTIRLE), (Pinner, *B.* 17, 184). Colourless fluid. Decomposes on distillation.

**BENZOXY-** v. BENZOYL-OXY-.

**BENZOXY-PROPIO-CARBOXYLIC ACID** v. CARBOXY-BENZOYL-PROPIONIC ACID.

**BENZOYL**. The radicle  $C_6H_5CO$ . Benzoyl derivatives obtained by displacement of H in amidegen, imidegen, or hydroxyl, are described under the compounds from which they are thus derived.

Di-benzoyl is called BENZIL (q. v.).

**BENZOYL-ACET-CARBOXYLIC ACID** v. ACETOPHENONE DI-CARBOXYLIC ACID.

**BENZOYL-ACETIC ACID**  $C_6H_5O$ , i.e.

$C_6H_5CO.CH_2.CO.H$ . Acetophenone *o*-carboxylic acid. [101°].

**Formation.**—1. From the ether by leaving it 24 hours with cold dilute KOH (3 per cent.), cooling to 0° and then adding dilute  $H_2SO_4$ . The acid is then ppt. as white flakes (Bayer a. Perkin, *B.* 15, 2705; 16, 2128; W. H. Perkin, jun., *C. J.* 45, 176).—2. From phenyl propiolic acid and conc.  $H_2SO_4$ , the solution being poured upon ice.—3. From the ether by allowing it to stand for 14 days with 20 vols. of conc.  $H_2SO_4$ , and then pouring upon ice (Perkin, *C. J.* 47, 210).

**Properties.**—Minute needles, which polarise light from benzene at 70° containing a little light petroleum. At 104° it melts, and gives off  $CO_2$ . Sl. sol. light petroleum, v. sol. alcohol, ether, hot benzene, and hot water.  $FeCl_3$  colours its alcoholic or aqueous solutions reddish-violet.

**Reaction.**—1. Heated alone or with dilute  $H_2SO_4$  it gives acetophenone and  $CO_2$ .—2. The ammonium salt gives with  $AgNO_3$  a pp. of  $Ag_2A$ ; with  $FeCl_3$  a blackish-violet pp.; with  $FeSO_4$  no pp.; with  $CuSO_4$  a greenish-yellow pp.

**Methyl ether** Me. An oil prepared by the action of conc.  $H_2SO_4$  on methyl-phenyl-propiolate (W. H. Perkin, jun. a. Calman, *C. J.* 49, 154).  $FeCl_3$  gives a violet colour in alcoholic solution. Sodium ethylate gives a white amorphous salt,  $C_6H_5CO.CHNa.CO.Me$ . This salt is v. sol. water and hot alcohol.

**Ethyl ether** A. Et. (265°–270°) at 760 mm.; (230°–235°) at 200 mm.

**Formation.**—1. From phenyl-propiolic ether (100 g.) and  $H_2SO_4$  (3000 g.) at 0°. After three

VOL. I.

hours the product is poured upon powdered ice, and the new body extracted with ether.—2. By heating diazo-acetic ether with benzoic aldehyde (Buchner a. Curtius, *B.* 18, 2371).—3. By heating  $EtONa$  (140 g.) with benzoic ether (300 g.) at 100°, mixing the product with acetic ether (350 g.) and heating for 15 hours at 100° (Claisen a. Lowman, *B.* 20, 651). 4. By the action of cold conc.  $H_2SO_4$  upon (*o*)-bromocinnamic ether (Michael a. Browne, *B.* 19, 1392).

**Properties.**—Colourless oil. Partly decomposed when distilled. Sl. sol. water, sol. alcohol and ether.

**Reactions.**—1. The alcoholic solution gives with  $FeCl_3$  a violet colour.—2. Boiled with water, or dilute  $H_2SO_4$ , it gives acetophenone, alcohol, and  $CO_2$ .—3. Boiling for 8 minutes produces di-hydro-benzoyl-acetic acid (q. v.). Boiling for 30 minutes forms two isomerides ( $C_{11}H_{10}O_3$ ). One of these ( $n = 8.7$ ) crystallises in plates, [275°], n. sol. hot alcohol, v. sl. sol. benzene; sol. alcoholic NaOH but ppt. by  $CO_2$ . The second ( $n = 4.7$ ) is an acid, not being ppt. by  $CO_2$  from its solution in alcoholic NaOH; conc.  $H_2SO_4$  forms a yellow solution, turning violet when warmed (Perkin, jun., *C. J.* 47, 262).—4.  $NaNO_2$  and  $H_2SO_4$  added to the sodium derivative produce an oxim of benzoyl-glyoxylic ether,  $Ph.CO.C(ONOH).CO.Et$  [121°], whence alkalis produce a substance  $C_{11}H_{10}O_3$  [125°].

**Metallic derivatives.**  $BzCHNaCO_2Et$ . Got by adding NaOEt to alcoholic solution of the ether. Silky needles, turns brown in air; insol. ether. —  $(C_{11}H_{11}O_3)_2Ba$ . —  $C_{11}H_{11}AgO_3$ . —  $(C_{11}H_{11}O_3)_2Cu$ : pale green; soluble in aqueous NaOH. On boiling  $Cu_2O$  is ppt.

**Nitrile** v. BENZOYL-ACETONITRILE.

**Benzylidene-benzoyl-acetic ether**

$C_6H_5CH:CH_2.CO_2Et$ . [99°]. From benzoyl-acetic ether and benzoic aldehyde, either by passing HCl at 0° into the mixture, or by heating in a sealed tube (Perkin, jun., *C. J.* 47, 210). Monoclinic prisms;  $a:b:c = 1.2730:1.7460$ ;  $\beta = 86^\circ 36'$ . Sol. hot methyl alcohol. Conc.  $H_2SO_4$  forms a yellow solution, which becomes colourless on heating.

**Benzylidene-di-benzoyl-di-acetic acid**

$(CO_2H.CH(Bz).CHPh)$ . [130°]. The ethers of this acid are formed by dropping diazo-acetic ethers (2 mols.) into benzoic aldehyde (3 mols.) at 170° (Buchner a. Curtius, *B.* 18, 2374). They dissolve in conc.  $H_2SO_4$  forming rose-coloured solutions, which turn brown on warming. The acid and its ethers give off a smell of hyacinth when burnt.

**Methyl ether** [113°]. prisms.

**Ethyl ether** [103°]. tables;  $NaOEt$  added to its ethereal solution gives  $(CO_2Et.CNaBz).CHPh$ .

**Di-benzoyl-acetic acid**  $CH(Bz).CO_2H$ . [109°].

Formed by the action of  $BzCl$  on sodium benzoyl-acetic ether, and saponification of the product with KOH (Bayer a. Perkin, jun., *B.* 16, 2133; *C. J.* 47, 240). Slender felted needles, sl. sol. cold alcohol and water, v. sol. ether; sol. aqueous alkalis.  $FeCl_3$  gives a red colouration. Conc.  $H_2SO_4$  gives no colour on warming.

**Reactions.**—1. Boiling water splits it up into di-phenyl-methylene-di-ketone,  $(C_6H_5CO)_2CH_2$ , and  $CO_2$ .—2. Boiling dilute  $H_2SO_4$  gives acetophenone, benzoic acid, and  $CO_2$ .

II

**Salt.—Ag.****Ethyl ether EtA'.** Oil; not solid at  $-10^{\circ}$ .**Methyl-benzoyl-acetic acid** is ( $\alpha$ )-Benzoyl-propionic acid (q. v.).**Ethyl-benzoyl-acetic acid**  $\text{BzCHEt.CO.H}$ . [ $111^{\circ}$ - $115^{\circ}$ ]. From NaOEt and EtI on alcoholic  $\text{BzCH.CO.Et}$ , and saponifying the oily product by allowing it to stand for some days with alcoholic KOH (Baeyer a. Perkin, jun., *B.* 16, 2180; *C. J.* 45, 180; 47, 240). Small needles, melts about  $115^{\circ}$  with slight decomposition. Easily soluble in alcohol, ether, and benzene. Boiled with dilute alcoholic KOH, it gives phenyl-propyl-ketone; benzoic and butyric acids are also formed, especially if the potash be strong.**Ethyl ether EtA'.** ( $232^{\circ}$ ) at 225 mm.**Propyl-benzoyl-acetic ether**  $\text{BzCHPr.CO.Et}$ . ( $239^{\circ}$ ) at 225 mm. Prepared like the preceding. Alkalis from phenyl-butyl-ketone.  $\text{PCl}_5$  forms  $\beta$ -chloro- $\alpha$ -propyl-cinnamic ether.**Isopropyl-benzoyl-acetic ether** $\text{BzCHPr.CO.Et}$ . ( $237^{\circ}$ ) at 225 mm. From benzoyl-acetic ether, Na, and PrI.**Iso-butyl-benzoyl-acetic ether** $\text{Bz.CH(CH}_3\text{).CHMe}_3\text{).CO.Et}$ . ( $217^{\circ}$ ) at 225 mm. Prepared like the preceding (Perkin a. Calman, *C. J.* 49, 165).**Di-ethyl-benzoyl-acetic acid**  $\text{BzCEt.CO.H}$ . [ $128^{\circ}$ - $130^{\circ}$ ]. From  $\text{Bz.CHEt.CO.Et}$  by NaOEt and EtI. The diethyl-benzoyl-acetic ether is saponified by standing for weeks with dilute alcoholic KOH (Baeyer a. Perkin, jun., *B.* 16, 2181; *C. J.* 45, 183). Heated alone or with dilute  $\text{H}_2\text{SO}_4$ , it gives off  $\text{CO}_2$ . Boiling dilute alcoholic KOH forms benzoic acid, diethylacetic acid, and di-ethyl-acetophenone (v. amyl-phenyl-ketone).**Tri-benzoyl-acetic ether.**  $\text{CBz}_3\text{.CO.Et}$ . From ethyl di-benzoyl-acetate, NaOEt, and  $\text{BzCl}$  (Perkin, jun., *C. J.* 47, 240). Thick yellow oil; sol. alcoholic KOH but reprecip. by water. Boiling dilute  $\text{H}_2\text{SO}_4$  forms acetophenone.**BENZYL-ACETIC-ALDEHYDE** $\text{C}_6\text{H}_5\text{.CO.CH}_2\text{.CHO}$ . Prepared by dissolving sodium (1 atom) in 20 or 30 times its weight of absolute alcohol, cooling to  $0^{\circ}$ , and adding acetophenone (1 mol.) and forming ether (1 mol.). On long standing the sodium compound separates as a granular pp.; this is dissolved in water and the aldehyde ppt. by acetic acid. Colourless unstable oil. Cupric acetate gives a pp. of bright green needles, which soon change to dark-green prisms. It reacts with amines very readily.**Anilide**  $\text{C}_6\text{H}_5\text{.CO.CH}_2\text{.CH.NC}_6\text{H}_5$ : [ $141^{\circ}$ ]; yellow prisms or plates; sol. hot alcohol.**p-Toluide**  $\text{C}_6\text{H}_4\text{.CO.CH}_2\text{.CH.NC}_6\text{H}_4$ : [ $160^{\circ}$ - $163^{\circ}$ ]; small yellow crystals.**( $\beta$ )-Naphthylamide** $\text{C}_{10}\text{H}_7\text{.CO.CH}_2\text{.CH.NC}_{10}\text{H}_7$ : [ $182^{\circ}$ ]; small bronzy crystals; sl. sol. almost all solvents (Claisen a. Fischer, *B.* 20, 2191).**BENZYL-ACETIMIDO-ETHYLIC ETHER** $\text{C}_6\text{H}_5\text{.CO.CH}_2\text{.C(NH).OEt}$ . ( $89^{\circ}$ - $5^{\circ}$  corr.).Benzoyl-acetonitrile  $\text{C}_6\text{H}_5\text{.CO.CH}_2\text{.CN}$  treated with alcoholic hydrochloric acid gives rise to  $\text{C}_6\text{H}_5\text{.CO.CH}_2\text{.C(NH)CHOEt}$  and this loses  $\text{HCl}$  when treated with ammonia giving the imido-ether (Haller, *B.* 23, 48, 24; *C. R.* 104, 1418).**Properties.**—Prisms or tables. V. sol. ether.**Reactions.**— $\text{KNO}_3$  and  $\text{H}_2\text{SO}_4$  give the nitroso-derivative  $\text{C}_6\text{H}_5\text{.CO.CH}_2\text{.C(N.NO).OEt}$  [ $117^{\circ}$ ],which gives Liebermann's reaction. The hydrochloride of the base dissolved in aqueous alcohol deposits  $\text{MH}_2\text{Cl}$  and benzoyl-acetic ether is left in solution.**Hydrochloride**  $\text{B'.HCl}$ . [ $140^{\circ}$  corr.]. Entangled needles. Insol. aq. and ether. Strongly irritates the mucous membranes.**BENZYL-ACETO-ACETIC ETHER** v. p. 21.**BENZYL-ACETO-CARBOXYLIC ACID** v.**ACETOPHENONE CARBOXYLIC ACID.****BENZYL-ACETONE**  $\text{C}_{10}\text{H}_{10}\text{O}_2$  i.e. $\text{C}_6\text{H}_5\text{.CO.CH}_2\text{.CO.CH}_3$ . Phenyl methyl methylene di-ketone. Acetyl-acetophenone. Acetyl-benzoyl-methane. [ $61^{\circ}$ ]. ( $261^{\circ}$ ).**Formation.**—By the action of dry NaOEt upon a mixture of acetone and benzoic ether (Claisen, *B.* 20, 655).**Preparation.**—1. Benzoyl-aceto-acetic ether, formed by the action of benzoyl chloride upon sodio-aceto-acetic ether, is boiled with water for a few hours; the yield is 25 p.c.—2. Prepared by adding acetophenone (1 mol.) to a cooled mixture of acetic ether (about 2 mols.) and alcohol-free sodium ethylate; yield: 80-90 p.c. of the acetophenone (Beyer a. Claisen, *B.* 20, 2078).**Copper compound**  $(\text{C}_{10}\text{H}_9\text{O}_2)_2\text{Cu}$ : formed as a pale green pp. by adding cupric acetate to the alcoholic solution. It is m. sol. alcohol and benzene, from which it crystallises in bright green needles.**Amide**  $\text{C}_6\text{H}_5\text{.CO.CH}_2\text{.C(NH).CH}_3$ : [ $143^{\circ}$ ]; clear glistening trimetric crystals,  $a:b:c = 99:27:1$ ;  $88:20$ .**Anilide**  $\text{C}_6\text{H}_5\text{.CO.CH}_2\text{.C(NPh).CH}_3$ : [ $110^{\circ}$ ]; plates. By warming with  $\text{H}_2\text{SO}_4$  (10 pts.) it is converted into (Py. 1:3)-phenyl-methyl-quinoline (Beyer, *B.* 20, 1770).**Properties.**—Crystals; distills undecomposed; volatile with steam. Sol. hot water, alcohol, and ether. Dissolves in alkalis with a yellow colour. Sl. sol. strong acids.  $\text{Fe}_2\text{Cl}_6$  gives a dark-red colouration.**Reactions.**—By warming with alkalis or by long boiling with acids it yields acetophenone. It has slightly acid characters, the H of the central  $\text{CH}_2$  group being replaceable as in aceto-acetic ether, since it lies between two CO groups. By heating with strong aqueous  $\text{NH}_3$  at  $120^{\circ}$  it is converted into the imideor  $\text{C}_6\text{H}_5\text{.CO.CH}_2\text{.C(NH).CH}_3$ . It condenses with (1 mol.) of phenyl-hydrazine with elimination of  $2\text{H}_2\text{O}$ , forming methyl-di-phenyl-pyrazol (Fischer a. Bülow, *B.* 18, 2131).**Salts.**— $\text{C}_{10}\text{H}_9\text{O}_2\text{.Na}$ : small yellowish plates. — $\text{C}_{10}\text{H}_9\text{O}_2\text{.Ag}$ : white pp.; v. sl. sol. water (Fischer a. Kuzel, *B.* 16, 2239).**Orim**  $\text{C}_{10}\text{H}_9\text{O}_2\text{.Ni.c.C}_6\text{H}_5\text{.C(NOH).CH}_2\text{.CO.CH}_3$  or  $\text{C}_6\text{H}_5\text{.CO.CH}_2\text{.C(NOH).CH}_3$ . ( $66^{\circ}$ ). Formed by heating benzoyl-acetone with hydroxylamine hydrochloride in alcoholic solution (Ceresole, *B.* 17, 812). White glistening scales. Volatile with steam. V. sol. acetone, benzene, and  $\text{CS}_2$ , insol. water.**Di-benzoyl-acetone**  $(\text{C}_6\text{H}_5\text{.CO})_2\text{.CH.CO.CH}_3$ . [ $102^{\circ}$ ]. Formed by the action of benzoyl chloride upon sodio-benzoyl acetone (Fischer a. Bülow, *B.* 18, 2133). Small needles. Sol. alcohol and ether, v. sl. sol. water. Sodium has no action upon it.

# BENZOYL-BENZOIC ACID.

**BENZOYL-ACETONIMIDE**  $C_{10}H_{11}NO$  i.e.  $C_6H_5C(OH)(CH_3)COCH_3$  or  $C_6H_5COCH_2C(OH)(CH_3)CH_3$  [143°]. Obtained by heating benzoyl acetone with strong aqueous  $NH_3$  at 120° (Fischer a. Bülow, *B.* 18, 2134). Distils undecomposed. Small plates, or large quadratic crystals. V. sol. dilute acids, by heating with which it is converted back into benzoyl-acetone and  $NH_3$ .

**BENZOYL-ACETONITRILE**  $C_9H_7NO$  i.e.  $C_6H_5COCH_2CN$ .

*Cyano-acetophenone*. [81° cor.]. Formed by the action of boiling water on benzoyl-cyanacetic ether  $C_6H_5COCH(CN).CO.Et$  (Haller, *Bl.* [2] 48, 23). White needles, sol. boiling water, alcohol, ether, and alkalis. Boiling conc.  $KOH$  acts thus:  $C_6H_5COCH(CN) + 2KHO + H_2O = NH_3 + C_6H_5CO.K + CH_3CO.K$ . In alcoholic solution gaseous  $HCl$  gives a body  $C_6H_5O.NCl$  (probably  $C_6H_5COCH_2C(NH)(Cl)OEt$  140corr.); whence ammonia in the cold gives the imido-ether  $C_6H_5COCH_2C(NH)OEt$ . If the action of the alcoholic  $HCl$  is prolonged, the products are the same as with  $KOH$ .

Silver salt  $C_6H_5COCHAgCN$ . White pp. Insol. aq and alcohol; sol. ammonia.

**BENZOYLACETOPHENONE** v. DI-PHENYL METHYLENE DI-KETONE.

**BENZOYL-ACETYL-ETHANE** v. ACETO-PHENONE-ACETONE, p. 36.

**Di-benzoyl-di-acetyl-ethane**  
 $C_{12}H_{10}O_4$  i.e.  $C_6H_5CO.CH(CO.CH_3)_2$ . Di-phenyl-

$C_6H_5CO.CH(CO.CH_3)_2$  di-methyl-acetylene-tetra-ketone [175°]. Formed by the action of an ethereal solution of iodine upon 2 mols. of solio-benzoyl-acetone (Fischer a. Bülow, *B.* 18, 2133). White needles. Sol. hot alcohol, sl. sol. ether, insol. water and dilute alkalis. Decomposed by boiling with alkalis.

**BENZOYL-ACRYLIC ACID**  
 $C_9H_7O_3$  i.e.  $C_6H_5CO.CH=CH.CO_2H$ . White plates, [64°], from water; after fusion its melting-point is altered to [97°]. Long needles, [99°] from toluene. Sl. sol. cold water and ligroin, v. sol. other solvents. Prepared by the action of  $AlCl_3$  on a mixture of benzene and maleic anhydride. By alkalis it is decomposed into acetophenone and glyoxylic acid. On heating by itself or with  $Ac_2O$ , it gives a red condensation product (Pechmann, *B.* 15, 885).

*Bromine addition product* [135°]. Colourless crystals.

**BENZOYL-ALLOPHANIC ACID** v. p. 127.

**BENZOYL-ALLYL-ACETIC ACID** v. ALLYL-BENZOYL-ACETIC ACID, p. 135.

**BENZOYL-AMIDO-** v. AMIDO-

**BENZOYL-AMIDO-ACETIC ACID** v. HIP-PURIC ACID.

**BENZOYL-AMMELINE**  $C_{10}H_{11}N_3O_2$  i.e.  $C_6H_5BzN_3O$ . From sodium cyanamide and  $BzCl$  (Gerlich, *J. pr.* [2] 13, 272). Brown resin, insol. water and ether, sol. alcohol and aqueous alkalis. Resolved by distilling in a current of hydrogen into benzonitrile, carbonic oxide, and cyanamide.

**BENZOYL-ANILIDE** v. ANILINE.

**BENZOYL-ANILINE** v. AMIDO-BENZOPHENONE.

**BENZOYL-ANISIDINE** v. Benzoyl-methyl-AMIDO-PHENOL.

**BENZOYL-AZOTIDE** v. p. 478.  
**BENZOYL-BENZENE** v. BENZOPHENONE.  
**Di-benzoyl-benzene** v. PHTHALOPHENONE.  
**BENZOYL-BENZIDINE** v. Di-AMIDO-DI-PHENYL.

**BENZOYL-BENZOIC-ACETIC ANHYDRIDE**  
 $C_{12}H_{10}O_5$  i.e.  $C_6H_5CO.C_6H_5CO.CO.C_6H_5$  [112°]. Prepared by heating *o*-benzoyl-benzoic acid with acetic anhydride to 100° (Freiher a. Pechmann, *B.* 14, 1865). Large crystals. Insol. alkalis. At 200 it decomposes into acetic and benzoyl-benzoic anhydrides.

***o*-BENZOYL-BENZOIC ACID**  $C_{12}H_{10}O_4$  i.e.  $C_6H_5CO.C_6H_4(CO_2H)$  [123]. *Benzophenone carbonylic acid*. Mól. w. 226. [87°] (Z.); [94°] (Hemilian, *B.* 11, 838).

*Formation*.—1. By oxidation of *o*-benzyl-toluene (Zincke a. Plaskuda, *B.* 6, 307), phenyl-*o*-tolyl-ketone (Behr a. Van Dorp, *B.* 7, 17), or di-benzyl-benzene (Zincke, *B.* 9, 32) with chromic mixture.

*Preparation*.—150 grms. of  $AlCl_3$  are slowly added during 3 hours to a solution of 100 grms. of phthalic anhydride in 1000 grms. of benzene (pure), the benzene is then poured off and can be used at once for a fresh operation, whilst the solid residue is washed with dilute  $HCl$  and with water, dissolved in  $Na_2CO_3$  and the acid precipitated from the solution by  $HCl$ , and finally recrystallised from xylene (3 pts.); the yield is 60 p.c. of the phthalic anhydride used (Friedel a. Crafts, *C. R.* 86, 1368; 92, 833; Freiher a. Pechmann, *B.* 13, 1612).

*Properties*.—Triclinic needles (containing aq.). When dry it melts at 128°.

*Reactions*.—1.  $P_2O_5$  at 190° forms anthraquinone.—2. *Hot fuming sulphuric acid* forms anthraquinone sulphonic acid (Liebermann, *B.* 7, 805).—3. *Sodium amalgam* first reduces it to  $C_{12}H_{12}CH(OH).C_6H_5CO.H$  and then to  $C_6H_5CH_2.C_6H_5CO.H$ .—4. *Resorcin, pyrogallol* &c., on heating, form phthalic acids. With phenyl-hydrazine it gives a condensation-product  $C_{12}H_{10}N_2Ph$  [182°] (Roser, *B.* 18, 805).

This forms small needles, sl. sol. alcohol, insol. water.

*Salts*. —  $CaA'$ . —  $BaA'_2$ . —  $ZnA'_2.2aq.$  —  $CuA'_2.aq.$

*Methyl ether*  $MeA'$ . [52°]: prisms.

*Ethyl ether*  $EtA'$ . [58°].

*Anhydride*  $(Bz.C_6H_4.CO)_2O$ . [120°] (Pechmann, *B.* 14, 1866).

*m*-Benzoyl-benzoic acid  $Ph.CO.C_6H_4.CO_2H$  [1:3]. [161°].

*Formation*.—1. From phenyl-*m*-tolyl-methane (10 g.),  $K_2Cr_2O_7$  (60 g.),  $H_2SO_4$  (90 g.) and water (270 g.) by boil.  $\frac{1}{2}$  for 3 days (Boiling; Senff, *A.* 220, 237). It is purified by reduction to  $Ph.CH(OH).C_6H_4.CO_2Na$  by sodium amalgam, crystallising this salt from water and oxidising again with  $H_2SO_4$  and  $K_2Cr_2O_7$ .—2. A quantitative yield is obtained by treating phenyl-*m*-tolyl-methane at 130° with bromine-vapour sufficient to form  $Ph.CH_2.C_6H_4.CH_2Br$  and treating the product with chromic mixture for 12 hours.—3. From  $Bz_2O$  (1 mol.) and  $BzCl$  (2 mols.) in presence of  $ZnCl_2$  (Doebner, *A.* 210, 277; *B.* 14, 648).—4. Formed as a by-product in the pre-

## BENZOYL-BENZOIC ACID

**Preparation of isophthalophenone by the action of  $\text{AlCl}_3$  on a mixture of benzene and iso-phthalyl chloride** (Ador, B. 18, 851).

**Properties.**—Long silky needles (from water or glacial acetic acid), or small plates (from alcohol). Sl. sol. cold water, v. sol. benzene of toluene, v. e. sol. alcohol or ether. May be sublimed as plates. Dissolves in conc.  $\text{H}_2\text{SO}_4$  giving no colour. Potash-fusion gives benzoic acid. Reduced by sodium-amalgam to *cro-oxy*-benzyl-benzoic acid (*q. v.*).

**Salts.**— $\text{BaA}'$ , 3aq: white crystalline powder.  $\text{BaA}'$ , 4aq: small plates.— $\text{CaA}'$ , 2aq: white crystalline powder.— $\text{AgA}'$ : white leaflets.

**Methyl ether**  $\text{MeA}'$  [62°].

**p-Benzoyl-benzoic acid**  $\text{C}_6\text{H}_4(\text{CO}_2\text{C}_6\text{H}_5)_2$  [14]. [191°]. Formed by oxidation of phenyl-p-tolyl-methane, phenyl-p-tolyl-ketone, p-phenyl-benzophenone or di-benzyl-benzene (Zincke, A. 161, 94; B. 6, 907; 9, 32; Goldschmidt, M. 2, 438). Monoclinic plates (from water). V. sl. sol. cold water; sl. sol. hot water (difference from the o-acid), v. sol. alcohol and ether, sl. sol. benzene. Sublimes in plates.

**Salts.**— $\text{CaA}'$ , 2aq: needles.— $\text{BaA}'$ , 2aq.  $\text{AgA}'$ : v. sl. sol. water.

**Methyl ether**  $\text{MeA}'$  [107°]. Satiny plates. **Ethyl ether**  $\text{EtA}'$  [52°]. Monoclinic.

**DI-BENZOYL-BENZOIC ACID**  $\text{C}_{14}\text{H}_{10}\text{O}_4$  i.e.  $(\text{C}_6\text{H}_5\text{CO})_2\text{C}_6\text{H}_4$ . Two acids of this composition are formed, together with an acid  $\text{C}_{14}\text{H}_{10}\text{O}_4$ , by oxidising the hydrocarbon  $\text{C}_{20}\text{H}_{14}$  obtained as a by-product in the preparation of benzyl-toluene (Weber a. Zincke, B. 7, 1153).

(a) Acid. [82°]. Resinous, and forms resinous salts. Potash fusion forms benzoic acid and a small quantity of an acid  $\text{C}_{14}\text{H}_{10}\text{O}_4$ .

(b) Acid. [212°]. Needles, insol. water, v. sol. alcohol and ether. Its salts are sl. sol. water. **Ethyl ether**  $\text{EtA}'$  [167°].

**DI-BENZOYL-BENZYLIDENE. DI-ACETIC ACID** v. **Benzylidene-di-benzoyl-di-acetic acid**.

**BENZOYL-BENZOTRICHLORIDE** v. **PHENYL TRI-CHLORO-TOLYL KETONE**.

**BENZOYL-BENZYL-ANILINE** v. **BENZYL-ANILINE**.

**BENZOYL-BENZYL CHLORIDE** v. **PHENYL CHLORO-TOLYL KETONE**.

**BENZOYL-BENZYLIDENE CHLORIDE** v. **PHENYL DI-CHLORO-TOLYL KETONE**.

**BENZOYL-BROMANILINE** v. **BROMO-ANILINE**.

**BENZOYL BROMIDE**  $\text{C}_6\text{H}_5\text{CO.Br}$  [19°] (V. v.) [a little below 0°]. S.G. 1.57. Colourless fluid, which fumes in the air.

**Preparation.**—Benzoic acid (500 pts.) is warmed with phosphorus tribromide (740 pts.) and the product is separated from the phosphorous acid by distillation *in vacuo*; the yield is 400 pts. (Claisen, B. 14, 2473). The so-called benzoyl bromide of Liebig and Wöhler (A. 3, 266) and of Paternò was probably benzylidene-bromide-benzoate,  $\text{C}_6\text{H}_5\text{CHBr}(\text{O}_2\text{C}_6\text{H}_5)$ , a compound of benzoic aldehyde with benzoyl bromide.

**BENZOYL-BROMO-NITRANILIDE** v. **BROMO-NITRO-ANILINE**.

**BENZOYL-BROMO-PHENOL** v. **BROMO-PHENOL**.

**DI-BENZOYL-ISOBUTYRIC ACID**  $(\text{C}_6\text{H}_5\text{CO.CH})_2\text{CH.CO}_2\text{H}$ . **Di-phenacyl-acetic acid**. [133°]. Formed by loss of  $\text{CO}_2$  by heat-

ing di-*p*-benzoyl-di-methyl-maleic acid  $(\text{Bz.OH})_2\text{C}(\text{CO}_2\text{H})_2$ . Silky needles. V. sol. alcohol, ether, acetic acid, and hot benzene, insol. ligroin. —  $\text{ANa}$ : glistening needles (Kues a. Paal, B. 19, 3147).

**BENZOYL-CARBAMIC ACID**  $\text{C}_6\text{H}_5\text{NHO}_2$ .

**Ethyl ether**  $\text{C}_6\text{H}_5\text{CO.NH.CO}_2\text{Et}$ . [110°]. Formed by boiling benzoyl-thiocarbamic ether in alcoholic solution with  $\text{PbO}$  (Lössner, J. pr. [2] 10, 254). Needles (from dilute alcohol), sl. sol. water. Decomposed by aqueous KOH into KOBz, alcohol,  $\text{NH}_3$ , and  $\text{K}_2\text{CO}_3$ . Alcoholic KOH gives a pp. of  $\text{C}_6\text{H}_5\text{CO.NK.CO}_2\text{Et}$ , v. e. sol. water.

**BENZOYL-CARBINOL**  $\text{Ph.CO.CH}_2\text{OH}$  [86°].  $\text{Ph.C(OH).CH}_2\text{OH}$  [74°]. **Ero-oxy-phenyl-methyl ketone**. **Oxy-acetophenone**. **Aceto-phenone alcohol**. **Phenacyl alcohol**.

**Formation.**—1. By the action of alkalis on the acetate or chloride,  $\text{C}_6\text{H}_5\text{CO.CH}_2\text{Cl}$ .—2. From phenyl-glycol (2 g.) and  $\text{HSO}_3$  (6 c.c. of S.G. 1.36). The mixture is warmed and, as soon as reaction sets in, it is cooled. The product is diluted, neutralised with  $\text{Na}_2\text{CO}_3$ , and the crystalline carbinol filtered off. Ether extracts a further quantity from the filtrate (Hunaeus a. Zincke, B. 10, 1187).

**Properties.** Prisms or plates (from benzoline). Large crystals (from alcohol or ether). V. sol. ether, alcohol, or  $\text{CHCl}_3$ . Large plates containing  $\text{H}_2\text{O}$  (from water or dilute alcohol). In drying these, decomposition readily occurs, benzoic aldehyde being formed. The carbinol combines with  $\text{NaHSO}_3$ . Readily reduces ammoniacal silver nitrate or Fehling's solution, the chief product of the oxidation being mandelic acid  $\text{C}_6\text{H}_5\text{CH(OH).CO}_2\text{H}$  (Breuer a. Zincke, B. 13, 635).

**Reactions.**—1. Heated alone it gives off benzoic aldehyde and a pungent body.—2. Heated with aqueous NaOH or baryta it becomes yellow and forms benzoic aldehyde.—3. Water at 140° acts similarly.—4. With HCN it yields the nitrile of atrogyric acid  $\text{CH}_2(\text{OH}).\text{CPh}(\text{OH}).\text{CO}_2\text{H}$  (Pfehl a. Blümlein, B. 16, 1290).

**Acetate**  $\text{Ph.CO.CH}_2\text{OAc}$ . [49°]. (270°). From chloro-acetophenone and  $\text{AgOAc}$  (Graebe, B. 4, 34); or from the carbinol and  $\text{Ac}_2\text{O}$  (Zincke). Trimetric tables (from benzoline). V. sol. alcohol, ether, or chloroform. M. sol. benzoline.

• **Benzoate**  $\text{Ph.CO.CH}_2\text{OBz}$ . [117°] (Zincke). From chloro-aceto-phenone and  $\text{AgOBz}$  or from benzoyl-carbinol and  $\text{Bz}_2\text{O}$ . Small tables (from dilute alcohol). V. sol. ether, benzene, or  $\text{CHCl}_3$ .

**BENZOYL-CHLORANILIDE** v. **CHLORO-ANILINE**.

**BENZOYL CHLORIDE**  $\text{C}_6\text{H}_5\text{CO.Cl}$ . [−1°] (Lieben, A. 178, 43). (198°). (194°) (Brühl, A. 235, 11). S.G. 1.21;  $\rho_D$  1.212 (B.). V.D. 4.99 (calc. 4.90).  $\rho_D$  1.5537. S.V. 126.3 (Ramsay).

**Formation.**—1. From chlorine and benzoic aldehyde (Liebig a. Wöhler, A. 3, 262).—2. From benzoic acid and  $\text{PCl}_5$  (Cahours, A. Ch. [3] 28, 334).—3. From benzoates and  $\text{POCl}_3$  (Gerhardt, A. Ch. [3] 37, 291).—4. In small quantities, by the action of Cl upon mandelic acid or on benzoic ethers (Malaguti, A. Ch. [2] 70, 374).—A

**B. 19, 3232).**—10. In considerable quantity by heating benzaldehyde with glycoooll (Curtius a. Lederer, *B. 19, 2462*).—11. Together with di- and tri-benzyl-amine, as a by-product, in the preparation of di-benzyl-hydroxylamine from hydroxylamine hydrochloride, benzyl chloride and NaOH (Walder, *B. 19, 3293*).

**Properties.**—Liquid, miscible with water, alcohol, and ether. Separated from water by KOH. Strongly alkaline, absorbs  $\text{CO}_2$ , forming a crystalline carbonate, and fumes with HCl. With cyanogen it forms a compound  $(\text{C}_6\text{H}_5\text{N})_2(\text{CN})_2$  [140°] which crystallises from alcohol, and forms a hydrochloride  $(\text{C}_6\text{H}_5\text{N})_2(\text{CN})_2\text{HCl}$  (Strakosch, *B. 5, 693*).

**Salts.**— $\text{B}^+\text{HCl}$ : large leaflets or flat tables. — $\text{B}^+\text{HBr}$ . — $\text{B}^+\text{H}_2\text{PtCl}_6$ : orange tables or yellow plates, sl. sol. water. —  $\text{B}^+\text{H}_2\text{SO}_4$ .

**Acetyl derivative**  $\text{C}_6\text{H}_5\text{CH}_2\text{NHAc}$  [61°; (300°); crystalline solid, sol. water (Amsel a. Hofmann, *B. 19, 1285*; Strakosch, *B. 5, 697*; Rudolph, *B. 12, 1297*).

**Di-benzylamine**  $\text{C}_{14}\text{H}_{19}\text{N}$  i.e.  $\text{NH}(\text{CH}_2\text{C}_6\text{H}_5)_2$ . S.G.  $\frac{1}{4}$  1.033.

**Formation.**—1. By the action of  $\text{NH}_3$  on  $\text{C}_6\text{H}_5\text{CH}_2\text{Cl}$  or by reduction of benzonitrile (v. supra). 2. By the action of bromine-water on tribenzylamine (Limpricht, *A. 144, 313*). — 3. By boiling benzoic aldehyde with ammonium formate (Leuckart a. Bach, *B. 19, 2128*). — 4. Occurs together with mono- and tri-benzylamine as a by-product in the preparation of di-benzyl-hydroxylamine from hydroxylamine hydrochloride, benzyl chloride, and NaOH. — 5. Formed by the action of  $\text{PCl}_5$  upon di-benzyl-hydroxylamine and treatment with water, the reaction probably being:

$$(\text{C}_6\text{H}_5)_2\text{N.OH} + \text{PCl}_5 = (\text{C}_6\text{H}_5)_2\text{N.O.PCl}_2 + \text{HCl} \text{ and } (\text{C}_6\text{H}_5)_2\text{N.O.PCl}_2 + 3\text{H}_2\text{O} = (\text{C}_6\text{H}_5)_2\text{NH} + \text{H}_3\text{PO}_4 + 2\text{HCl} \text{ (Walder, } B. 19, 3287).$$

**Properties.**—Liquid, insol. water, v. sol. alcohol and ether. Does not absorb  $\text{CO}_2$  from the air. On distillation it decomposes into *s*-di-phenyl ethane, *s*-di-phenyl ethylene, lophine, and various bases (Brunner, *A. 151, 133*).

**Salts.**— $\text{B}^+\text{HNO}_2$ : [186°], very sparingly soluble thin glistening needles. —  $\text{B}^+\text{HCl}$  [256°]. —  $\text{B}^+\text{HBr}$  [276°]. —  $\text{B}^+\text{HI}$  [224°]. —  $\text{B}^+\text{H}_2\text{PtCl}_6$ : golden-yellow needles.

**Nitrosamine**  $(\text{C}_6\text{H}_5\text{CH}_2)_2\text{N.NO}$ : [61°]; white crystals: v. sol. alcohol and ether, insol. water (W. cf. Rohde, *A. 151, 366*).

**Picryl derivative**  $(\text{C}_6\text{H}_5\text{CH}_2)_2\text{N.OC}_6\text{H}_2(\text{NO})_3$ : [171°]; orange plates.

**Formyl derivative**  $(\text{C}_6\text{H}_5\text{CH}_2)_2\text{N.CHO}$ : [52°]; (above 360°) (Leuckart a. Bach, *B. 19, 2128*).

**Di-sulphonic acid**  $\text{C}_{14}\text{H}_{13}\text{N}(\text{SO}_3\text{H})_2$  (Limpricht, *A. 144, 317*). —  $\text{BaA}''$ .

**Tri-benzylamine**  $\text{C}_{18}\text{H}_{21}\text{N}$  i.e.  $(\text{C}_6\text{H}_5\text{CH}_2)_3\text{N}$ . [91°].

**Formation.**—1. From benzyl chloride and  $\text{NH}_3$  (v. supra).—2. By heating di-benzylamine with benzyl chloride at 100° (Walder, *B. 19, 3287*).—3. Together with mono- and di-benzylamine as a by-product in the preparation of di-benzyl-hydroxylamine from hydroxylamine hydrochloride, benzyl chloride, and NaOH (W.). 4. By heating benzaldehyde with rather more than an equal weight of ammonium formate; the yield is 40 p.c. of the benzaldehyde em-

ployed (Leuckart, *B. 18, 2341*). White plates (from hot alcohol); v. sl. sol. water. When heated for a long time with MeI or EtI at 150°, benzyl iodide and tetra-methyl- (or ethyl-) ammonium iodide are formed (Marquardt, *B. 19, 1027*). Fuming sulphuric acid forms  $\text{C}_{18}\text{H}_{21}(\text{SO}_3\text{H})_3\text{N}$  (Limpricht, *A. 144, 311*).

**Salts.**— $\text{B}^+\text{HCl}$ : [228°]; thick prisms or iridescent plates, v. sol. hot alcohol, insol. water. —  $\text{B}^+\text{H}_2\text{Cl}_2\text{PtCl}_6$ : orange yellow needles. —  $\text{B}^+\text{HNO}_2$ : [125°; insol. water. —  $\text{B}^+\text{HBr}$ : [208°]. —  $\text{B}^+\text{HBr}$ . —  $\text{B}^+\text{HI}$ : [178°]. —  $\text{B}^+\text{H}_2\text{SO}_4$ : 12aq: [110°]; sol. water.

**Methylo-iodide**  $\text{B}^+\text{MeI}$ : [184°]; needles or plates; sol. hot alcohol, sl. sol. cold water.

**Methylo-hydrate**  $\text{B}^+\text{MeOH}$ : crystalline solid; alkaline reaction; v. sol. water. On heating it evolves MeOH forming tri-benzylamine.

**Methylo-chloride-platinum-salt**  $(\text{B}^+\text{MeCl})_2\text{PtCl}_6$ : [197°]; orange pp.; insol. cold water and alcohol.

**Ethylo-iodide**  $\text{B}^+\text{EtI}$ : [190°]; colourless rhombic crystals; sol. alcohol and hot water.

**Isopropylo-iodide**  $\text{B}^+\text{PrI}$ : [170°]; needles; sl. sol. hot water.

**BENZYLAMINE-*or*-DI-SULPHONIC ACID**  $\text{C}_6\text{H}_5\text{CH}_2(\text{SO}_3\text{H})_2\text{NH}(\text{SO}_3\text{H})$ . The di sodium salt  $\text{A}''\text{Na}_2$  3aq is formed by shaking benzaldioxin with a 30 p.c. sodium bisulphite solution. It crystallises in small white needles, v. e. sol. water, insol. cold alcohol. By warming with dilute acids it is split up into benzaldehyde, sodium sulphate, and ammonium sulphite:  $\text{C}_6\text{H}_5\text{CH}_2(\text{SO}_3\text{Na})_2\text{NH}(\text{SO}_3\text{Na}) + 2\text{H}_2\text{O} = \text{C}_6\text{H}_5\text{CHO} + \text{Na}_2\text{SO}_4 + (\text{NH})_2\text{HSO}_4$ .

Alkalis decompose it in the cold, and water on boiling (Fechmann, *B. 20, 2539*).

**BENZYL-ANILINE**  $\text{C}_6\text{H}_5\text{CH}_2\text{NH}(\text{C}_6\text{H}_5)$ . [33° uncor.]. (above 360°). Obtained by reducing thio-benzoyl-aniline (Bernthsen a. Trompeter, *B. 11, 1760*). Formed also by boiling diazobenzene-benzyl-anilide (50 g.) with HCl (200 c.c.); the yield is 20 g. (Friswell a. Green, *B. 19, 2036*). Yellowish crystals.

**Salts.**— $\text{B}^+\text{HCl}$  [203° uncor.]; white plates; decomposed by water. —  $\text{B}^+\text{H}_2\text{Cl}_2\text{PtCl}_6$  [168° uncor.]; slender yellow needles; tolerably easily soluble in water. —  $\text{B}^+\text{C}_6\text{H}_5\text{O}_4$ . —  $\text{B}^+\text{CdCl}_2$ .

**Benzoyl derivative** [104°] (Fleischer, *A. 138, 229*).

**Di-benzyl-aniline**  $\text{C}_{18}\text{H}_{19}\text{N}(\text{CH}_2\text{C}_6\text{H}_5)_2$ . [67°] (above 300°). Prepared by heating a mixture of aniline (51 pts.), benzyl chloride (150 pts.) and NaOH (30 pts.) on the water-bath for three or four weeks. After cooling the solidified cake is pressed, distilled with steam to remove excess of benzyl chloride, washed with hot water, and crystallised from alcohol. Colourless needles. V. sol. ether, benzene, hot alcohol and hot acetic acid, sl. sol. cold alcohol and cold acetic acid, nearly insol. water. Weak base.

**Salts.**— $\text{B}^+\text{HCl}$  4aq: glistening prisms. —  $\text{B}^+\text{H}_2\text{Cl}_2\text{PtCl}_6$ : thin orange-yellow scales. Picrate  $\text{B}^+\text{C}_6\text{H}_5(\text{NO}_2)_3\text{OH}$ : [132], long yellow needles (Matzudaira, *B. 20, 1611*).

**TRI-BENZYL-ARISINE** v. p. 322.

**BENZYL-BARBITURIC ACID** v. BARBITURIC ACID.

**BENZYL-BENZENE** v. DI-PHENYL-METHANE, *p*-Di-benzyl-benzene  $\text{C}_{18}\text{H}_{19}$ , i.e.  $(\text{C}_6\text{H}_5\text{CH}_2)_2\text{C}_6\text{H}_4$ . [86°]. Formed, together with

the *o*-isomeride and di-phenyl methane, by the action of zinc on a mixture of benzyl chloride and benzene, or by the action of  $H_2SO_4$  on a mixture of benzene and methylal,  $CH_3(OMe)_2$ . (Zincke, *B.* 6, 119, 221; 9, 81). Transparent laminae, sl. sol. ether, v. sol. benzene and hot alcohol.  $CrO_3$  forms (a)-dibenzoyl-benzene and *p*-benzoyl-benzoic acid.

*o*-Di-benzyl-benzene  $(C_6H_5CH_2)_2C_6H_4$ . (78°). Silky needles (from alcohol); v. sol. ether and alcohol.  $CrO_3$  forms *o*-di-benzoyl-benzene and *o*-benzoyl-benzoic acid.

#### BENZYL BENZOATE $C_6H_5CH_2O_2C_6H_5$ , i.e.

$C_6H_5CH_2O_2CO.C_6H_5$ . (324° i.v.). [21°]. S.G. (fluid, at 19°) 1.1221. From benzyl alcohol and  $BzCl$  (Kraut, *A.* 152, 130). Formed also by several days' heating of benzaldehyde at 100° with a small quantity of sodium benzoate; probably the compound  $C_6H_5C(OC_6H_5)_2ONa$  is first formed and then decomposes into benzyl benzoate and sodium benzoate, which latter again reacts upon a further quantity of benzaldehyde, producing more of the intermediate product, and so on. Large colourless crystals (Claisen, *B.* 20, 616).

*o*-BENZYL-BENZOIC ACID  $C_6H_5CH_2O_2C_6H_4$ , i.e.  $C_6H_5CH_2O_2C_6H_4CO_2H$ . Mol. w. 212. [114°]. From *o*-benzoyl-benzoic acid and sodium-amalgam (Rotering, *J.* 1875, 598; *B.* 9, 633). Slender needles; may be sublimed; sl. sol. cold water, v. sol. alcohol and ether.  $CaA^{+}2aq. - CaA^{+}3_2 aq. BaA^{+}5_4 aq. AgA^{+} MeA^{+}$ .

#### *m*-Benzyl-benzoic acid

$PhCH_2C_6H_4CO_2H$ . [108°].

**Formation.**—1. From *exo*-oxy-benzyl-benzoic acid,  $PhCH(OH).C_6H_4CO_2H$  and conc.  $HCl$  at 170°.—2. From *exo*-bromo-*m*-toluic acid,  $CH_2Br.C_6H_4CO_2H$  and  $AlCl_3$  (Senff, *A.* 220, 247). Yield 50 p.c. of theoretical from toluic acid.—3. A small quantity from benzoic ether, benzyl chloride, and  $ZnCl_2$  by boiling.

**Properties.**—Short slender needles (from hot water), small plates (from hot dilute alcohol); sl. sol. cold water, m. sol. hot water, v. s. sol. alcohol, ether or chloroform. Conc.  $H_2SO_4$  forms a colourless solution.  $K_2Cr_2O_7$  and  $H_2SO_4$  give *m*-benzoyl-benzoic acid.  $-CaA^{+}2aq. - BaA^{+}4aq. AgA^{+} MeA^{+}$ .

#### *p*-Benzyl-benzoic acid

$PhCH_2C_6H_4CO_2H$  [141°]. [155°].

**Formation.**—1. By oxidising *p*-benzyl-toluene with dilute  $H_2SO_4$  (Zincke, *A.* 161, 106).—2. By reducing *exo*-oxy-*p*-benzyl benzoic acid with  $HI$ .—3. From *p*-benzoyl-benzoic acid and sodium-amalgam or  $HI$  and  $P$  (Graebe, *B.* 8, 1054).

**Properties.**—Minute needles (from water); may be sublimed; sl. sol. cold water, v. sol. alcohol and ether. Chromic mixture oxidises it to *p*-benzoyl-benzoic acid.  $-CaA^{+}11A^{+} - BaA^{+}2aq. AgA^{+}$ .

**BENZYL BROMIDE  $C_6H_5CH_2Br$ . (199°). S.G. 1.4380.**

**Formation.**—1. From benzyl alcohol and  $HBr$  (Kekulé, *A.* 137, 190).—2. From  $Br$  and boiling toluene (Beilstein, *A.* 113, 369; Jackson & Field, *Ann.* 2, 11).—3. From benzyl chloride and  $AsH_3$  (Brix, *A.* 225, 163).

**Preparation.**—By the action of bromine (1 mol.) upon cold toluene (1 mol.) in direct sunshine; the yield is quantitative (Schramm, *B.* 18, 608).

**Properties.**—Fungent liquid. The zinc-copper couple acts vigorously upon it, producing two isomeric benzylenes. In presence of ether, the zinc-copper couple produces dibenzyl,  $ZnBr_2$ , and  $C_6H_5ZnBr$ , whence water produces toluene:  $2C_6H_5ZnBr + 2H_2O = 2C_6H_6 + ZnBr_2 + Zn(OH)_2$ . In presence of alcohol, the couple produces toluene and  $EtOZnBr$ . In presence of water, the couple produces dibenzyl and a little toluene (Gladstone & Tribe, *C. J.* 47, 448).

#### BENZYL BUTYRATE $C_6H_5CH_2O_2C_4H_9$ , i.e.

$C_6H_5CH_2O_2CO.Pr.$  (240°). S.G.  $\frac{16}{17.5}$  1.016 (Conrad & Hodgkinson, *A.* 193, 320).

#### Benzyl isobutyrate $Me_2CH.CO_2CH_2Ph$ .

(228° i. v.). S.G.  $\frac{13}{17.5}$  1.016. Prepared by boiling an alcoholic solution of benzyl chloride and potassium isobutyrate for five days with inverted condenser. The product is mixed with water and the oil distilled.

**Properties.**—Oil, with pleasant odour.

**Reactions.**—When benzyl isobutyrate (90 g.) is heated with sodium, (8 g.) a violent action occurs, the products being hydrogen, sodic isobutyrate, benzylic benzyl-isobutyrate (*q.v.*), sodic benzoate, toluene, and an oil ( $C_{11}H_{14}O$ )<sub>n</sub>, (340°–350°). The principal reaction is:

(W. R. Hodgkinson, *C. J.* 33, 496).

#### *α*-BENZYL-ISOBUTYRIC ACID $C_6H_5CH_2O_2C_4H_9$ , i.e. $Me_2C(CH_3)Ph.CO_2H$ .

**Benzyl ether  $(C_6H_5)_2A^{+}$ . (280°–285°). S.G.  $\frac{15}{17.5}$  1.0285.** Prepared by the action of sodium on benzyl-isobutyrate (*q.v.*).

**Reactions.**—1. Heated with sodium a violent action occurs, toluene, sodic benzoate, sodic benzyl-isobutyrate and an oil,  $C_{11}H_{14}O$  (350°–355°) being formed.—2. It is attacked by alkalis with great difficulty, the saponification gives isobutyric and benzyl-isobutyric acid (W. R. Hodgkinson, *C. J.* 33, 503; *A.* 201, 171).

**BENZYL CARBAMATE  $NH_2.CO.O.C_6H_5$ . [86°].** From benzyl alcohol and urea nitrate at 140° (Campisi & Annato, *B.* 4, 412) or solid cyanogen chloride (Cannizzaro, *B.* 3, 518). Large plates (from water); sl. sol. hot water, v. sol. alcohol. Decomposes above 200° into benzyl alcohol and cyanuric acid.

#### BENZYL-CARBAMIC ACID $C_6H_5NH.CO.OH$ .

**Benzyl-ammonium salt  $C_6H_5NH.CO_2NH_4C_6H_5$ . [99°].** From benzylamine and  $CO_2$ . Formed also by heating *α*-amido-phenyl-acetic acid at 260°; the yield being nearly the theoretical (Tiemann & Friedländer, *B.* 14, 1969). Plates, sol. water and alcohol, insol. ether; volatile with steam. Decomposed by acids or alkalis into  $CO_2$  and benzylamine.

#### BENZYL DI-CARBOXY-GLUTACONIC ACID v. DI-CARBOXY-GLUTACONIC ACID.

#### DIBENZYL-CARBOXYLIC ACID v. DI-PHENYL-ETHANE-CARBOXYLIC ACID.

#### DIBENZYL DI-CARBOXYLIC ACID v. DI-PHENYL-SUCCINIC ACID and DI-PHENYL-ETHANE DI-CARBOXYLIC ACID.

#### BENZYL CARBINOL v. PHENYL-ETHYL ALCOHOL.

**BENZYL CHLORIDE  $C_6H_5CH_2Cl$  i.e.  $C_6H_5CH_2Cl$ . Mol. w. 126.5. *α*-Chloro-toluene. (176°) at 754 mm. S.G.  $\frac{17}{4}$  0.9453. S.V. 138.45 (Schiff, *B.* 19, 563; *A.* 220, 98); 133.18 (Ramsay).**

## BENZYL-DI-ETHYL-AMINE

**Formation.**—1. From benzyl alcohol and HCl (Cannizzaro, *A.* 88, 139; 90, 346; Deville, *A. Ch.* [3] 8, 178).—2. By distilling toluene in a current of chlorine (Lauth & Grimaux, *Bl.* 1887, i, 105).

**Preparation.**—By passing chlorine (1 mol.) into cold toluene (1 mol.) exposed to direct sunshine; the yield is nearly theoretical (Schramm, *B.* 18, 608).

**Properties.**—Oil, sol. alcohol and ether.

**Reactions.**—1. Boiling alcoholic KOH forms  $C_6H_5OEt$ .—2. Alcoholic KOAc forms  $C_6H_5OAc$ .—3. Alcoholic KCN forms  $C_6H_5CN$ .—4. Alcoholic  $NH_3$  forms, on heating, mono-, di-, and tri-benzylamine.—5. Hot dilute  $HNO_3$  (or a nitrate) forms benzoic aldehyde.—6. Boiling  $Pb(OH)_2$  forms benzyl alcohol.—7.  $KPh$  forms phenyl benzyl oxide.—8. Water at 180 gives a product which, on distillation, yields benzyl-toluene and anthracene. Before distillation the product is perhaps  $C_6H_5CH_2C_6H_4CH_2Cl$  (Van Dorp, *B.* 5, 1070; Zincke, *B.* 7, 276).—9. Long boiling with water (30 vols.) produces benzyl alcohol.—10. Sodium-amalgam produces a little *s*-diphenyl-ethylene.—11. Aromatic hydrocarbons in presence of powdered zinc give off HCl and form condensation products (Zincke, *B.* 6, 137).—12. Chloroformic ether and sodium form diphenyl-ethane exo-carboxylic ether,  $PhCH_2CH(Ph)CO_2Et$  (Wurtz, *C. R.* 70, 350).—13. Heated with  $AlCl_3$  it gives off HCl, forming toluene and anthracene (Perkin, jun. & Hodgkinson, *C. J.* 37, 726).—14. In carbon disulphide solution yields, when chromyl chloride is added gradually, a brown precipitate of composition  $PhCH_2Cl, CrO_2Cl_2$ , slowly converted by moist air into benzoic aldehyde:

The compound heated to 170° loses HCl, forming a compound  $PhCHClCrO_2Cl$ , which also yields benzoic aldehyde.

$3PhCH_2Cl.O.CrO_2Cl + 3H_2O \\ \rightarrow 6HCl + Cr_2O_3 + 3PhCHO$  (Etard, *A. Ch.* [6] 22, 235).—15.  $HCl$  reduces it to toluene.—16. Zinc dust gives toluene, phenyl-tolyl-methane, and anthracene (Frost, *Bl.* [2] 46, 249).

**BENZYL-CHLORO-MALONIC ACID** v. CHLORO-BENZYL-MALONIC ACID.

**BENZYL-CINCHONINE** v. CINCHONINE.

**$\alpha$ -BENZYL-CINNAMIC ACID**  $C_{15}H_{14}O_2$  i.e.  $C_6H_5CH_2C(CH_3Ph)CO_2H$ . [157°]. Formed by the action of alkalis on the compound  $Ph.SO_2C(CH_3Ph)_2CO_2Et$  (Michael & Palmer, *Am.* 7, 70). Large white needles, insol. water, sol. alcohol.

***p*-BENZYL-CRESOL**  $C_9H_9CH_2C_6H_4Me.OH$ . (240°) at 40 mm. From benzyl chloride, cresol, and zinc (Mazzara, *G.* 2, 303; 11, 438; 12, 264).

**Reactions.**—1. Chloro-acetic acid and KOHAc form  $C_6H_5CH_2C_6H_4Me.OCH_2CO_2H$  [111°].—2. (*a*)-chloropropionic acid forms  $C_6H_5CH_2C_6H_4Me.OCHMe.CO_2H$  [115°].—3.  $CO_2$  and Na forms  $C_6H_5CH_2C_6H_4(OH)CO_2Na$ .

**Acetyl derivative**  $C_{15}H_{14}AcO$ . (245°) at 40 mm.

**BENZYL CRESYL OXIDE**  $C_9H_9CH_2OC_6H_4CH_3$  v. Tolyl ether of BENZYL ALCOHOL.

**BENZYL CYANAMIDE**  $C_6H_5N_2$  i.e.

$C_6H_5CH_2NH.CN$ . [83°]. Formed by passing  $CyCl$  into benzylamine in ether (Strakosch, *B.* 6, 694). Plates (from ether); insol. water, v. s. sol. alcohol and ether. On keeping it changes to isomeric tri-benzyl-melamine. Boiling  $HCl$  forms benzyl-urea.

**Di-benzyl-cyanamide**  $(C_6H_5CH_2)_2N.CN$ . [54°]. From  $CyCl$  and dibenzylamine in alcohol (Limpicht, *A.* 144, 317). Plates; insol. water.

**BENZYL CYANATE**  $C_6H_5CH_2N.CO$ . (175°-200°). Formed, together with benzyl cyanurate, by the action of silver cyanate on benzyl chloride or bromide (Letts, *C. J.* 25, 416; Ladenburg & Struve, *B.* 10, 46). Pungent liquid. Changes spontaneously into the cyanurate. Alcoholic  $NH_3$  converts it into benzyl-urea.

**BENZYL CYANIDE** v. PHENYL-ACETONITRILE.

**BENZYL CYANURATE**  $(C_6H_5CH_2)_3N_3C_3O_3$ . [157°] (above 320°). The chief product of the action of silver cyanate on benzyl chloride (v. *supra*); formed by isomeric change from benzyl cyanate. Silky needles (from alcohol), insol. water. Potash fusion gives  $K_2CO_3$  and benzylamine.

**BENZYL CYMENE**  $C_{11}H_{14}$  i.e.

$C_6H_5CH_2C_6H_4MePr$ . [297°] (Mazzara, *G.* 8, 508; 308°) (Weber, *J.* 1878, 402). S.G. 1.397. From benzyl chloride, cymene, and zinc. On oxidation it gives benzoyl-terphenylacetic acid.

**Benzyl-cymene disulphonic acid**

$C_{11}H_{12}(SO_3H)_2$  (M.).

**BENZYL-DURENE** v. BENZYL-TETRA-METHYL-BENZENE.

**BENZYLENE**  $(C_6H_5)_2$ . Two hydrocarbons of this composition are formed by the action of the copper-zinc couple upon benzyl bromide (or chloride). (*a*)-benzylene, [42°;  $\mu$ , 6091, is a yellowish-red resin, sl. sol. alcohol, v. sol. ether and benzene. (*B*)-benzylene is a brown resin, insol. alcohol or ether (Gladstone & Tribe, *C. J.* 47, 448).

**BENZYLENE-** v. BENZYLIDENE-

**BENZYLENE-DIAMINE** v. AMIDO BENZYL-AMINE.

**BENZYLENE-IMINE**  $C_{11}H_{12}$  i.e.

*o*-nitro-benzyl-chloride with  $SnCl_4$  in conc.  $HCl$ . Greyish yellow powder. Sol. chloroform and acetic acid. Dissolves in  $HCl$  to a red fluorescent solution. The salts are amorphous. The hydrochloride forms a reddish-yellow transparent solid ( $BHCl$ ). Theoplatinochloride ( $BH_2PtCl$ ) is an insoluble, amorphous, reddish-brown powder (Lellmann & Stickel, *B.* 19, 1611).

**BENZYL ETHER**  $C_6H_5CH_2O$  i.e.  $(C_6H_5CH_2)_2O$ . Di-benzyl ether, Di-benzyl oxide. (298° i. v.)  $d_4^{20} 1.036$ ,  $\mu$  1.5525. Formed by heating benzyl alcohol with  $B_2O_3$  at 120° (Cannizzaro, *A.* 92, 115). Also by heating benzyl chloride with water at 190° (Limpicht, *A.* 139, 313). From benzyl chloride and sodium benzyliate (Lowe, *C. J.* 51, 700). Decomposed by heat into toluene and benzoic aldehyde.

**BENZYL-DI-ETHYL-AMINE**  $C_{11}H_{17}N$  i.e.  $C_6H_5CH_2NEt_2$ . (212° cor.). From benzylamine and  $EtI$  at 130° (Ladenburg & Struve, *B.* 10, 47, 561, 1152, 1634); or from di-ethyl-amine and

benzyl chloride at 100° (V. Meyer, B. 10, 810, 964).

**Ethyl-iodide**  $C_2H_5CH_2NEt_2I$ . Large crystals, v. sol. water. On dry-distillation it gives triethylamine and benzyl iodide.— $C_2H_5CH_2NEt_2I$  [87°]— $(C_2H_5CH_2NEt_2Cl)_2PtCl_2$ .

**Di-benzyl-ethyl-amine**  $C_{15}H_{19}N$  i.e.  $(C_2H_5CH_2)_2NCH_2CH_2C_6H_5$ . From di-benzyl-amine and EtI (Limpricht, A. 144, 815).— $BHCl$ .

**Ethyl-iodide**  $(C_2H_5CH_2)_2NEt_2I$ . Sl. sol. cold water.

**BENZYL-ETHYL-BENZENE**  $C_{15}H_{16}$  i.e.  $C_6H_5CH_2C_2H_5Et$  [14]. Mol. w. 196. (295° i.v.). S.G. 12.99. From benzyl chloride, ethylbenzene, and zinc (Walker, B. 5, 686) or from *p*-ethylbenzophenone, HI, and P (Söllscher, B. 15, 1682). Oxidation gives *p*-benzoyl-benzoic acid.

**BENZYL ETHYL OXIDE** v. **BENZYL ALCOHOL**.

**BENZYL ETHYL KETONE**  $C_{10}H_{12}O$  i.e.  $C_6H_5CH_2CO.C_2H_5$ . Mol. w. 148. (c. 226°). S.G. 12.190. From phenyl-acetyl chloride and ZnEt<sub>2</sub> (Popoff, B. 5, 501). Does not combine with  $NaHSO_4$ . Oxidised by  $CrO_3$  to benzoic and propionic acids.

**BENZYL-*p*-ETHYLPHENYL-CARBINOL**  $C_{15}H_{18}CH(OH).C_6H_5CH_2$  (1:1). (350°). Liquid. Formed by heating benzyl ethylphenyl ketone with alcoholic KOH at 160°. Boiled with dilute  $H_2SO_4$  it gives phenyl-ethylphenyl-ethane (Söllscher, B. 15, 1681).

**BENZYL ETHYLPHENYL-*p*-KETONE**  $C_{15}H_{16}CH_2CO.C_6H_5CH_2$  (1:1). *Ethyl-desoxybenzoin*. (61°). Prepared by the action of  $AlCl_3$  on a mixture of ethylbenzene and phenyl-acetyl chloride (Söllscher, B. 15, 1680). Boils undecomposed. V.D. 8.03 (obs.). Small plates. Sol. ether, benzene, and hot alcohol, sl. sol. cold alcohol. On oxidation it gives terephthalic acid. On reduction it gives phenyl-ethylphenyl-ethane.

**BENZYL-ETHYLPHENYL-METHANE** v. **PHENYL-ETHYLPHENYL-ETHANE**.

**BENZYL DI-ETHYL SULPHINE**. *Platinchloride*  $(C_6H_5CH_2SEt)_2PtCl_2$ . From EtI and di-benzyl sulphide, the product being treated with AgCl and  $PtCl_2$  successively (Schöller, B. 7, 1271).

**DI-BENZYL-ETHYL pseudo-THIOUREA**  $C_{15}H_{19}N_2S$  i.e.  $C_6H_5CH_2C(NH_2)NH$ . Formed by heating di-benzyl-thiourea with ethyl iodide at 100°. Oil.

Salts.  $EtHI$ : (93°); monoclinic prisms; v. sol. alcohol, sl. sol. water.  $BH_2SO_4$ : large four-sided rhombic soluble tables.— $BH_2PtCl_2$ : fine needles (Römörus, B. 19, 2349).

**BENZYL-FLUORENE**  $C_{23}H_{18}$  i.e.

$C_6H_5CH_2C_6H_4\langle\begin{smallmatrix} CH_2 \\ C_6H_5 \end{smallmatrix}\rangle$ . [102°]. Formed by heating fluorene with benzyl chloride and zinc-dust (Goldschmidt, M. 2, 413). Plates (from alcohol).

**BENZYL-FORM-ALDEHYDE** v. **PHENYL-ACETIC ALDEHYDE**.

**DI-BENZYL-GLYCOLLIC ACID**  $C_{18}H_{16}O_5$  i.e.  $(C_6H_5CH_2)_2C(OH)CO_2H$ . *Oxatoluic acid*. *α-Oxy-di-phenyl iso-butyric acid*. [157°].

**Formation**.—1. From the nitrile and conc. HCl at 140°–160° (Spiegel, A. 219, 46; B. 13, 2313; 14, 1687).—2. By boiling vulpic acid (g. v.) with aqueous KOH:  $C_{15}H_{15}O_3 + 8H_2O$

$= CH_2O + 2CO_2 + C_6H_5O_2$  (Möller a. Strecker, A. 118, 56).

Rhombic prisms (from alcohol): *a:b:c* = 5113:1:3058. Fluffy mass of needles (from benzene). Salt.— $AgA$ .

**Reactions**.—1.  $HNO_3$  gives a viscid nitro-acid (Möller a. Strecker).—2. Conc. aqueous KOH gives toluene and oxalic acid on boiling.—3. Treated with  $PCl_5$  and  $H_2O$  successively a monophosphate,  $C_{15}H_{15}O_3PO_2H_2$ , crystallising in prisms, [160°] is formed.

**Acetyl derivative**. [106°]. Plates in rosettes (from  $CHCl_3$  mixed with petroleum).

**Methyl ether**  $MeA$ : [71°]; needles.

**Anhydride**  $C_{15}H_{12}O_2$ . [169°]. Got by heating the acetyl derivative. Prisms (from benzene). V. sol. alcohol and ether.  $Na_2CO_3$ ,  $Aq$  converts it into sodium di-benzyl-glycolate.

**Nitrile**  $(C_6H_5CH_2)_2C(OH)CN$ . [118°]. From di-benzyl ketone, KCN and HCl. Colourless flat rhombs (from alcohol). At 113° it splits up into HCN and di-benzyl ketone.

**Amide**. [193°]. From the nitrile and conc. HCl at 125°. Fluffy mass of long needles.

**BENZYL-GLYOXALINE**  $C_7H_5(C_6H_5)_2N_2$  [71°]. (310°). Formed by the action of benzyl chloride on glyoxaline (Wallach, B. 16, 539). Colourless crystals. Sl. sol. ether, insol. cold water.— $BH_2Cl$ ,  $PtCl_2$ : yellow pp., insol. cold water.

**DI-BENZYL-GUANIDINE**  $C_{15}H_{17}N_3$  i.e.  $(C_6H_5CH_2NH)_2C:NH$ . [100°]. Formed by boiling benzylamine hydrochloride with benzylcyanamide in alcohol (Strakosch, B. 5, 695).—*Lamine* (from alcohol). Sol. water, alcohol, and ether.— $BHCl$ : [176°].

**BENZYL-HYDROXYLAMINE** v. **HYDROXYLAMINE**.

**BENZYLIDENE**. The radicle  $C_6H_5CH$ , also called *benzyl* or *benzylene*. The latter name is more appropriate to the isomeric radicle  $C_6H_4CH_2$ .

**BENZYLIDENE-DI-ACETAMIDE**  $C_{17}H_{19}N_2O_2$  i.e.  $C_6H_5CH(NH.CO.CH_3)_2$ . Formed by boiling acetamide with benzoic aldehyde (Roth, A. 154, 72; Z. [2] 4, 650; 6, 680). Silky crystals, sl. sol. cold water and ether. Not affected by boiling KOH aq but decomposed by hot  $HCl$  aq into benzoic aldehyde and  $NH_4Ac$ .

**BENZYLIDENE-DI-ACETATE**  $C_{17}H_{15}O_5$  i.e.  $CHPh(OAc)_2$ . *Di-acetyl-benzoic ortho-aldehyde*. [45°]. From benzoic aldehyde and  $Ac_2O$  or from benzylidene chloride and  $AgOAc$  (Genthner, A. 106, 251; Wicke, A. 102, 368; Hübner, Z. 1867, 277; Neuhof, A. 146, 323; Limpricht, A. 139, 321; Porkin, Z. 1868, 172).

**BENZYLIDENE-ACETIC ACID** v. **CINNAMIC ACID**.

**Benzylidene-di-acetic acid** v. **PHENYL-GLUTARIC ACID**.

**BENZYLIDENE-ACETO-ACETIC ACID** v. p. 24.

**BENZYLIDENE-DI-ACETO-ACETIC-ETHER**  $C_{25}H_{25}O_6$  i.e.  $C_6H_5CH[CH(CO_2Et)(CO_2CH_3)]_2$ . [153°]. Formed together with dehydro-benzylidene-di-acetoacetic ether  $C_{15}H_{15}O_5$ , by the action of benzoic aldehyde (1 mol.) upon acetoacetic ether (2 mols.) in presence of a primary amine. Long white needles. Sl. sol. cold alcohol and ether (Hantzsch, B. 18, 2588).

**Dekhyde-benzylidene-di-acetacetic-ether**  

$$\text{C}_6\text{H}_5\text{O}, \text{ possibly } \text{EtOO}-\text{C}-\text{CH}=\text{C}-\text{CO}_2\text{Et}$$

$\text{MeC}-\text{O}-\text{CMe}$   
 [88°]. Formed as described above. Glistening prisms. V. sol. cold or hot solvents (Hantzsch, B. 18, 2583).

**BENZYLIDENE-DI-ACETONAMINE** v. p. 27.  
**BENZYLIDENE-ACETONE**  $\text{C}_{10}\text{H}_{16}\text{O}$  i.e.  
 $\text{Ph.CH:CH.CO.CH}_3$ . *Aceto-cinnamone*. *Methylstyryl ketone*. [42°] (152°) at 25 mm. (261° i.v.) at 760 mm.

**Formation.**—1. From benzoic aldehyde, acetone and a little  $\text{ZnCl}_2$  at 260° (Claisen a. Claparède, B. 14, 2461). 2. By heating a mixture of calcium acetate with calcium cinnamate; also in small quantity by heating cinnamic aldehyde with Na and MeI at 130°, or by boiling cinnamic aldehyde with MeOH and  $\text{ZnCl}_2$  (Engler a. Leist, B. 6, 254).

**Preparation.**—From benzoic aldehyde (20 g.), acetone (40 g.), water (1800 c.c.) and aqueous (10 p.c.) NaOH (20 g.) in the cold. After four days the oil that has separated is extracted with ether, dried over  $\text{CaCl}_2$  and rectified *in vacuo* (Claisen a. Ponder, A. 223, 138).

**Properties.**—Plates, apparently rectangular. It has an odour of coumarin and rhubarb and attacks the skin. Easily soluble in alcohol, ether, benzene, and chloroform, less in petroleum-ether. In conc.  $\text{H}_2\text{SO}_4$  it forms an orange solution. Forms a crystalline compound with  $\text{NaHSO}_4$ , and a di-bromide  $\text{C}_{10}\text{H}_{14}\text{OBr}_2$  [125°] crystallising in needles from alcohol.

**Phenyl hydrazone**  $\text{C}_{15}\text{H}_{14}\text{N}_2$ : [156°]; flat yellow needles; sol. hot alcohol, sl. sol. cold alcohol and ether, insol. water (Fischer, B. 17, 576; Knorr, B. 20, 1099).

**Oxime**  $\text{Ph.CH:CH.C(=NOH).CH}_3$ : [116°]. (220°) at 100 mm. Forms a bromide, [145°]; and an acetyl derivative [91°] (Zelinsky, B. 20, 922).

**Di-benzylidene-acetone**  
 $\text{Ph.CH:CH.CO.CH:CH.Ph}$ . *Cinnamone*. *Di-styryl ketone*. [112°].

**Formation.**—From benzoic aldehyde (20 pts.), acetone (6 pts.), and acetic acid (40 pts.), by adding  $\text{H}_2\text{SO}_4$  (30 pts.) at 0° or passing in  $\text{HCl}$ .

**Preparation.**—From benzoic aldehyde (10 g.), acetone (3 g.), water (100 g.) and dilute (10 per cent.) NaOH (20 g.) left 4 days in the cold; or from benzylidene-acetone (7 g.), benzoic aldehyde (5 g.), water (200 g.), alcohol (150 g.) and dilute NaOH (20 g.) (Claisen a. Ponder, A. 223, 142; cf. Claisen a. Claparède, B. 14, 350, 2460; Schmidt, B. 14, 1459).

**Properties.**—Bright yellow monoclinic tablets (from acetone or  $\text{CHCl}_3$ )  $a:b:c = 4.8:6.1:1.378$   $\beta = 78^\circ 43'$ . Readily soluble in chloroform or acetone, less in ether or cold alcohol. Gives an orange solution in  $\text{H}_2\text{SO}_4$ .

**Tetrabromide**  $\text{C}_{10}\text{H}_{14}\text{OBr}_2$ : white needles [208°–211°].

**BENZYLIDENE-DIACETONE-ALCAMINE**  
 $\text{H}_2\text{C}=\text{CH}(\text{OH})-\text{CH}_2$   
 $\text{C}_{11}\text{H}_{19}\text{NO}$  i.e.

$(\text{C}_6\text{H}_5)\text{HC}=\text{NH}-\text{C}(\text{CH}_3)_2$   
*Oxy-phenyl-di-methyl-tetra-hydro-pyridine*. Thick colourless oil. Formed by reduction of an acid solution of benzylidene-di-acetonamine

(v. p. 97) with sodium-amalgam.— $\text{BFHCl}$ : small crystals, easily soluble in water and alcohol (Fischer, B. 16, 2236).

**BENZYLIDENE-DI-ACETONINE** v. p. 34.  
**BENZYLIDENE-ACETOPHENONE**

$\text{C}_6\text{H}_5\text{CH:CH.CO.C}_6\text{H}_5$ . *Phenyl styryl ketone*. *Phenylcinnamonyl ketone*. *Benzylidene-methyl-phenyl ketone*. *Benzal-acetophenone*. [58°]. (317°–318°). Formed by passing  $\text{HCl}$  gas into a mixture of acetophenone and benzaldehyde; by adding  $\text{H}_2\text{SO}_4$  to the two latter bodies diluted with acetic acid; by heating them with acetic anhydride to 170°; or by treating them with dilute NaOH (Claisen a. Claparède, B. 14, 2463; Claisen a. Ponder, A. 223, 148).

**Preparation.**—12 pts. of acetophenone are mixed with 10.5 pts. of benzaldehyde and 3 pts. of a 20 p.c. sodium methylate solution, and allowed to remain in the cold for a few days when the whole will have solidified to a crystalline mass; the yield is 90 p.c. of the theoretical (Claisen, B. 20, 637). Large trimetric tables. V. sol. chloroform, ether, benzene and  $\text{CS}_2$ , m. sol. alcohol, sl. sol. petroleum ether. On oxidation it gives benzoyl-formic and benzoic acids. On boiling with dilute acids it is decomposed into acetophenone and benzaldehyde. By reduction with  $\text{H}$  and  $\text{P}$  it is converted into di-benzyl-methane. The  $\text{HCl}$  addition product  $\text{C}_{11}\text{H}_{12}\text{O.CHCl.CHCl.C}_6\text{H}_5$ , [120°] forms colourless trimetric plates, sparingly soluble in cold alcohol and ether. It is prepared by the addition of gaseous  $\text{HCl}$  to the ketone. The di-bromide  $\text{C}_{11}\text{H}_{10}\text{O.CHBr.CHBr.C}_6\text{H}_5$ , [157°] forms short colourless prisms sol. hot alcohol. Prepared by the addition of bromine to the ketone.

**BENZYLIDENE- $\beta$ -ACETYL-PROPIONIC ACID**  $\text{C}_{12}\text{H}_{14}\text{O}_4$  i.e.  $\text{CHPh:CH}_2\text{CO.CH}_2\text{CH}_2\text{CO}_2\text{H}$ . *Benzylidene-larvulinic acid*. *Cinnamoyl-propionic acid*. [120°–125°]. Formed by heating levulinic acid with benzoic aldehyde and sodium acetate. Small white crystals. The lead salt is insoluble. Dissolves in cold conc.  $\text{H}_2\text{SO}_4$  with a red colouration. Boiling conc.  $\text{KOH}$  splits off benzaldehyde. Reduction in alkaline solution yields benzyl-valero-lactone  $\text{C}_{11}\text{H}_{14}\text{O}_2$ , which forms large prisms of melting-point [86°] (Erdmann, B. 18, 3441).

**BENZYLIDENE-ISOAMYL-AMINE**. An oil formed from benzoic aldehyde and isoamylamine (Schiff, A. 140, 93).

**BENZYLIDENE-DI-ISOAMYL-DI-OXIDE**  $\text{C}_{12}\text{H}_{18}\text{CH}(\text{OC}_4\text{H}_9)_2$ . (292° cor.). From benzylidene chloride and  $\text{NaOC}_4\text{H}_9$  (Wicke, A. 102, 363).

**BENZYLIDENE-ANILINE**  $\text{C}_{11}\text{H}_{11}\text{N}$  i.e.  $\text{C}_6\text{H}_5\text{CH:NPh}$ . *Amide of benzoic aldehyde*. [49°] (Fiemann a. Piest, B. 15, 2028).

**Formation.**—1. By warming aniline with benzoic aldehyde (Laurant a. Gerhardt, *Compt. chim.* 1850, 117).—2. By heating di-phenylthio-urea with benzoic aldehyde (Schiff, A. 148, 336).

**Properties.**—Lamine; volatile with steam, insol. water, v. c. sol. alcohol and ether. At 200° it changes to an isomeride which differs from it in forming a salt  $\text{B}^+\text{H}_2\text{PtCl}_2$ .

**Hydrocyanide**  $\text{C}_{11}\text{H}_{11}\text{N}_2$ . [82°]. Formed by passing  $\text{HCN}$  into fused benzylidene-aniline, or by the action of  $\text{KCN}$  on a mixture of benzoic aldehyde and aniline hydrochloride dissolved

in alcohol (Coch, B. 11, 246). It forms concentric needles, insol. alkalis and dilute acids.

**BENZYLIDENE-DI-ANTIPYRINE** *v. Di-ox-TETRA-METHYL-DI-QUINIZYL-PHENYL-METHANE.*

**DI-BENZYLIDENE-BENZIDINE**  $C_{22}H_{18}N_2$ , i.e.  $C_{12}H_8(N:CHPh)_2$ . [232°] (C.); [239°] (B). Obtained by heating hydrazo-benzene or benzene-azo-benzene with benzoic aldehyde and  $ZnCl_2$  (Clève, *Bl.* [2] 45, 188; Barzilovsky, *J. R.* 1885, 366). Yellow scales (from benzene and chloroform). Resolved by HCl into benzoic aldehyde and benzidine.

**BENZYLIDENE-DI-BENZAMIDE**

$C_{22}H_{18}N_2O_2$ , i.e.  $C_6H_5CH(NH.CO.C_6H_5)_2$ . [197°]. Formed by heating benzoic aldehyde with benzamide (Both, A. 151, 76). Long silky needles (from alcohol), insol. water. Resolved by hot HClAq into the parent substances.

**BENZYLIDENE-DI-BENZOATE**

$C_{22}H_{18}O_4$ . From benzylidene chloride and AgOBz (Eugenhart, J. 1857, 471). Crystalline.

**BENZYLIDENE-BENZYL-AMINE**

$C_{17}H_{15}N$ , i.e.  $C_6H_5CH_2.N:CH.C_6H_5$ . (c. 300°). Formed by the action of PCl upon di-benzyl-hydroxylamine, probably by intermediate formation of the chloride ( $C_6H_5CH_2.NCl$ ). Oil. V. sol. alcohol and ether, insol. water.

Salts.  $BHCl$ : [251°]; long plates or tables; v. sol. alcohol, sparingly in cold water, more readily in hot.  $BH_2PCl_2$ : small golden-yellow crystals (Waller, B. 19, 1632).

**BENZYLIDENE-BROMIDE**  $C_7H_5Br_2$ , i.e.  $C_6H_5CHBr_2$ . Benzal bromide. *o*-Di-bromotoluene. (130°-140°) at 20 mm. From benzoic aldehyde and  $PBr_3$ . Can only be distilled *in vacuo*. Sol. in 180 forms toluene and di-benzyl (Michaelson a. Lippmann, *Bl.* [2] 4, 251).

**BENZYLIDENE-BROMIDE-BENZOATE**

$C_{21}H_{17}BrO_2$ , i.e.  $C_6H_5CH(O_2C.C_6H_5)_2$ . [70°]. Colourless tables or prisms. Sol. alcohol, ether, and acetic acid. Prepared by mixing benzaldehyde and benzoyl bromide. On distillation it again decomposes into these bodies (Claisen, *B.* 14, 2175; cf. Liebig a. Wohler, A. 3, 266).

**BENZYLIDENE-DI-BUTYRAMIDE**

$C_{22}H_{28}N_2O_4$ , i.e.  $C_6H_5CH_2NH.CO.C_4H_9$ . Slender crystals formed by heating butyramide with benzoic aldehyde (Strecker, A. 151, 76).

**BENZYLIDENE-DI-CARBAMIC ACID**

$C_8H_8CH_2NH.CO.OH$ . Ethyl ether EtA". [171°]. From carbamic ether, benzoic aldehyde, and HCl (Bischoff, B. 7, 634). Crystals; may be sublimed. Propyl ether PrA". [143°] (Bischoff, B. 7, 1032).

**BENZYLIDENE-CHLORAL-AMMONIA**

$C_{12}H_{11}ClNO$ , i.e.  $CCl_3.CH(OH).N:CH.C_6H_5$ . [130°]. White leaflets. Decomposed by dilute acids and by boiling water. Prepared by the action of benzoic aldehyde on chloral ammonia (Schiff, B. 11, 2166).

**BENZYLIDENE-CHLORIDE**  $C_7H_5Cl$ , i.e.  $C_6H_5CHCl_2$ . Benzal chloride. Chlorobenzol. Benzene chloride. Mol. w. 161. (204°) at 76 mm. S.G.  $\frac{1}{4}$  1.27. S.V. 154-25 (Schiff, B. 19, 563).

Formation.—1. From benzoic aldehyde and  $PCl_5$  (Cahours, A. 70, 39; *Suppl.* 2, 253, 306).

2. By passing chlorine into boiling toluene (Beilstein, A. 118, 886; 146, 822; Lauth a. Grimaux, *Bl.* 2, 347).—3. From benzoic aldehyde and succinyl chloride (Bembold, A. 188, 189) or  $COCl_2$  (Kempf, Z. 1871, 79).

Preparation.—1. By passing 2 mols. of chlorine into cold toluene (1 mol.) exposed to direct sunshine (Schramm, B. 18, 608).—2. By heating toluene (7 pts.) with  $PCl_5$  (30 pts.) at 190°; the yield being nearly that calculated (Colson a. Gautier, *Bl.* [2] 45, 87).

Properties.—Oil, with faint odour.

Reactions.—1. Converted into benzoic aldehyde by water or aqueous  $K_2CO_3$  at 130°, or by warming with  $H_2SO_4$  at 60° and treating the product with water (Oppenheim, B. 2, 213).—2. Alcoholic KHS forms benzyl disulphide and di-thio-benzoic acid.—3. Red-hot soda lime forms benzene (Limprieth, *Bl.* 1896, ii. 467).—4. Chlorine forms *p*-chloro-benzylidene chloride. 5. Nitric acid forms *p*-nitro-benzylidene chloride (Hübner a. Bente, B. 6, 803; cf. Beilstein, A. 146, 333).—6.  $AgOAc$  forms  $C_6H_5CH(OAc)_2$ . 7. Silver oxalate forms benzyl disulphide (Golowskinsky, A. 111, 252).—8. Na forms di-phenyl-ethylene.—9. MeI and Na form cumene.—10.  $NH_3$  forms hydrobenzamide.—11.  $ZnEt_2$  diluted with benzene forms  $C_6H_5$ , di-ethyl-phenyl-methane and  $C_2H_5$  (Dale, M. 4, 618). 12. Copper at 100° gives  $C_6H_5Cl$ ,  $C_6H_5Cl_2$  and  $C_6H_5CHCl.C_6H_5$  (Onufrowicz, B. 17, 833).

**BENZYLIDENE-DI-CHLORO-CHROMIC ACID** *v. TOLUENE.*

**DI-BENZYLIDENE-ETHYLENE-DIAMINE**

$C_{20}H_{18}N_2$ , i.e.  $C_6H_5(N:CH.C_6H_5)_2$ . [54°]. Formed by heating ethylene-diamine (1 mol.) with benzoic aldehyde (2 mols.) to 120°. Large colourless tables. V. sol. alcohol and benzene, insol. water. Decomposed into its constituents by acids (Mason, B. 20, 270).

**BENZYLIDENE-ETHYLENE-DI-SULPHIDE**

$C_{12}H_8S_2$ , i.e.  $C_6H_5CH(S_2.C_6H_5)_2$ . [29°]. Formed by passing  $HCl$  gas into a mixture of equal mols. of benzaldehyde and ethylene sulphuride. Crystals. Easily soluble in alcohol, ether, and benzene, insoluble in water. Very stable body. By the action of bromine upon the chloroform solution di-ethylene-tetra-sulphide  $C_6H_5(S_2)_2C_6H_5$  is formed (Fashbender, B. 20, 460).

**BENZYLIDENE-DI-ETHYL-DIOXIDE**

$C_{18}H_{18}O_2$ , (222° cor.) Diethyl derivative of benzoic ortho-aldehyde. From benzylidene chloride and  $NaOEt$  (Wicke, A. 102, 863).

**BENZYLIDENE-DI-HEPTYLENE-TETRA-UREA**  $C_{42}H_{54}N_8O_4$ , i.e.

$C_6H_5CH_2NH.CO.NH.C_6H_{11}.NH.CO.NH_2$ . From benzoic aldehyde and heptylene-diurea (Schiff, A. 151, 195). Insoluble powder.

**BENZYLIDENE-MALONIC ACID**

$Ph.CH(CO_2H)_2$ . [196°] (C.); [193°] (S). Formation.—1. From the ether by aqueous baryta.—2. From benzoic aldehyde, malonic acid and  $Ac_2O$  at 100° (Claisen a. Crismer, A. 218, 135).—3. From benzoic aldehyde, sodic malonate, and glacial acetic acid at the ordinary temperature;  $Ph.CHO + CH_2(CO_2Na)_2 = Ph.CH(CO_2Na)_2 + H_2O$ . The product is diluted with water, shaken out

## BENZYLIDENE-PHTHALIDE.

with ether, acidified, shaken again with ether and the ether distilled off (Stuart, *C. J.* 43, 405; v. also Claisen, *A.* 218, 129).

**Properties.**—Colourless glassy prisms. Sl. sol. cold water, v. s. sol. hot water, v. sol. alcohol, acetic ether or acetone, m. sol. ether or glacial acetic acid. Insol. benzene, chloroform or petroleum. Does not give in neutral solutions a pp. with  $\text{BaCl}_2$ ; but on warming such a mixture needles of the salt  $\text{BaA}$  separate (characteristic reaction).

**Salt.**— $\text{AgA}$ .

**Reactions.**—1. At  $200^\circ$  it splits up into  $\text{CO}$ , and cinnamic acid.—2. Boiling water decomposes it into benzoic aldehyde and malonic acid, some  $\text{CO}$ , and cinnamic acid being also formed. 3. Reduced by sodium amalgam to benzyl malonic acid  $\text{Ph.CH}_2\text{CH}(\text{CO}_2\text{H})_2$ .—4. Bromine acts on its solution in chloroform forming  $\text{Ph.CBrBr.CBr}(\text{CO}_2\text{H})_2$  [96] whence water forms  $\alpha$ -bromo-cinnamic acid (Stuart, *C. J.* 49, 360).—5. Cold alcoholic potash forms crystals of  $\text{Ph.CH}(\text{OEt})\text{CH}(\text{CO}_2\text{K})_2$ , whence a silver salt,  $\text{Ph.CH}(\text{OEt})\text{CH}(\text{CO}_2\text{Ag})_2$ , may be got. The free acid, if heated rapidly, melts at  $120^\circ$ – $130^\circ$ , splitting up into  $\text{EtOH}$  and benzylidene-malonic acid, which then solidifies again, and melts a second time at  $190^\circ$ . By crystallisation from water the acid is partly split up into alcohol and benzylidene-malonic acid.—6.  $\text{HBr}$  forms  $\beta$ -bromophenyl-isocinnamic acid  $\text{Ph.CHBBr.CH}(\text{CO}_2\text{H})_2$ , which is decomposed by water into  $\text{HBr}$ , cinnamic acid and  $\text{CO}$  (Stuart, *C. J.* 49, 360).

**Ethyl ether EtA**, [32]. (192°) at 17mm. S.G. 1.111. Formed by passing  $\text{HCl}$  into a mixture of malonic ether and benzoic aldehyde or by treating the mixture with  $\text{Ac}_2\text{O}$  at  $160^\circ$  (Claisen, *B.* 14, 348). Large transparent crystals (Stuart, *C. J.* 49, 360). Boils at  $308^\circ$ – $312^\circ$  with decomposition.

**BENZYLIDENE-MESITYL-OXIDE**  $\text{C}_{12}\text{H}_8\text{O}$  i.e.  $(\text{CH}_3)_2\text{C}:\text{CH}:\text{CO}:\text{CH}:\text{CH}:\text{C}_6\text{H}_3$ . (173°) at 14 mm. Oil. Prepared by passing  $\text{HCl}$  gas into a mixture of mesityl oxide and benzaldehyde (Claisen, *B.* 14, 351). Forms a tetrabromide [118°].

**BENZYLIDENE-METHYL-KETOLE**  $\text{C}_{12}\text{H}_{12}\text{N}_2$  [248°]. Colourless plates. Formed by reduction of dimethyl-rosindole  $\text{C}_{12}\text{H}_{12}\text{N}_2$  with zinc-dust and  $\text{NH}_3$ . It is oxidised in acetic acid solution by  $\text{FeCl}_3$  back to di-methyl-rosindole (Fischer & Wagner, *B.* 20, 816).

**BENZYLIDENE-DI-METHYL-DI-OXIDE**  $\text{C}_8\text{H}_8\text{CH}(\text{OMe})_2$ . Di-methyl derivative of benzoic orthoaldehyde. (208° cor.). From benzylidene chloride and  $\text{NaOMe}$  (Wicke, *A.* 102, 363).

**BENZYLIDENE-DI-METHYL-p-PHENYL-ENE-DIAMINE**  $\text{C}_{12}\text{H}_{12}\text{CH.N.C}_6\text{H}_4\text{NMe}_2$ . Benzylidene-amido-di-methyl-aniline. Methyl-phenylene-diamide of benzoic aldehyde [98°]. Glistening plates or needles. Sol. hot alcohol and benzene, sl. sol. cold alcohol. Weak base. Formed by mixing benzoic aldehyde and  $\alpha$ -di-methyl-p-phenylene-diamine, either directly or in alcoholic solution. By  $\text{HCl}$  it is split up into its generators.— $\text{D}^{\text{H}}\text{Cl}_2$ : white solid (Calm, *B.* 17, 2940).

**BENZYLIDENE-(Py.3)-METHYL-QUINOL-INE**  $\text{C}_{12}\text{H}_{12}\text{N}_2$  i.e.

Vol. I.

by heating quinaldine (methyl-quinolone) with benzoic aldehyde or benzylidene chloride and  $\text{ZnCl}_2$  (Jacobsen & Reimer, *B.* 16, 2606). Glistening colourless needles. Sublimable. Sol. hot alcohol, insol. water.— $\text{D}^{\text{H}}\text{Cr}_2\text{O}_7$  [214]: very sparingly soluble reddish-yellow needles.

**BENZYLIDENE-(8)-NAPHTHYLAMINE**  $\text{C}_{12}\text{H}_9\text{CH.N.C}_8\text{H}_7$ . [103°]. From benzoic aldehyde and (8)-naphthylamine (Claisen, *A.* 237, 261).

**BENZYLIDENE-(a)-NAPHTHYLAMINE-p-SULPHONIC ACID**  $\text{C}_{12}\text{H}_9\text{CH.N}(\text{CH}_2\text{C}_6\text{H}_4\text{SO}_3\text{H})_2$ . The sodium salt ( $\text{A}^{\text{Na}}$ ) is obtained by shaking a strong solution of sodium-(a)-naphthylamine-sulphonate with benzaldehyde. By long boiling with water it is split up into its constituents (Cahn & Lange, *B.* 20, 2601).

**BENZYLIDENE-DI-(8)-NAPHTHYL-OXIDE**  $\text{C}_{12}\text{H}_8\text{CH} < \text{C}_{10}\text{H}_7 > \text{O}$ . Anhydride of di-oxynaphthyl-phenyl-methane. [190°]. Crystalline solid. Insoluble in aqueous alkalis.

**Formation.**—1. By heating a solution of (8)-naphthol and benzoic aldehyde in acetic acid to  $200^\circ$ , or with addition of  $\text{H}_2\text{SO}_4$  or  $\text{HCl}$  on the water-bath (Trzebinski, *B.* 17, 499).—2. By warming benzylidene di-naphthyl di-oxide  $\text{C}_{12}\text{H}_8\text{CH}(\text{O.C}_8\text{H}_7)_2$  with acetic acid and a few drops of  $\text{HCl}$ . In these reactions di-oxynaphthyl-phenyl-methane  $\text{C}_{12}\text{H}_8\text{CH}(\text{C}_{10}\text{H}_7\text{OH})_2$  must first be formed and at once split off  $\text{H}_2\text{O}$  (Claisen, *B.* 19, 3317).

**Benzylidene-di-(8)-naphthyl-di-oxide**  $\text{C}_{22}\text{H}_{18}\text{O}_2$  i.e.  $\text{C}_{12}\text{H}_8\text{CH}(\text{OC}_{10}\text{H}_7)_2$ . Di-naphthyl ortho-benzaldehyde. [205°]. From benzoic aldehyde (5.3 pts.), (8)-naphthol (7.2 pts.), glacial  $\text{HOAc}$  (30 pts.), and fuming  $\text{HCl}$  (2 pts.) at  $0^\circ$  (Claisen, *A.* 237, 269). Tables, sl. sol.  $\text{CHCl}_3$  and  $\text{CS}_2$ , v. sl. sol. alcohol and ether, insol. alkalis. Conc.  $\text{H}_2\text{SO}_4$  gives, on gentle warming, a deep-red solution.  $\text{HOAc}$  and some  $\text{HCl}$  slowly convert it at  $100^\circ$  into benzylidene-di-naphthyl oxide, a change which also occurs when it is heated at  $210^\circ$ .

**BENZYLIDENE OXAMIDE**  $\text{C}_{12}\text{H}_{12}\text{N}_2\text{O}_2$ . Formed by warming oxamic ether with benzoic aldehyde (Medicus, *A.* 157, 50). Laminae.

**BENZYLIDENE-PHENYL-DIAMINE**  $\text{C}_{12}\text{H}_{12}\text{N}_2$ . PHENYL-BENZAMIDINE.

**DI-BENZYLIDENE-p-PHENYLENE DI-AMINE**  $\text{C}_{20}\text{H}_{16}\text{N}_2$  i.e.  $\text{C}_6\text{H}_4(\text{N}:\text{CHPh})_2$ . [140°]. From  $p$ -phenylenediamine and benzoic aldehyde at  $120^\circ$  (Ladenburg, *B.* 11, 590). Plates (from alcohol). Resolved by hot  $\text{HClAq}$  into the parent substances.

**BENZYLIDENE-PHTHAL-ETHYL-IMIDINE**  $\text{C}_{12}\text{H}_{12}\text{ON}$  i.e.  $\text{C}_6\text{H}_4 < \text{CH}(\text{C}_2\text{H}_5) > \text{N} \cdot \text{Et}$ . Ethyl-phthalmyl-benzyl. [c.  $77^\circ$ ]. Formed by boiling the ethyl-amide of decybenzoic-o-carboxylic acid  $\text{C}_{12}\text{H}_9(\text{CO.NHEt})\text{CO}.\text{CH}_2\text{C}_6\text{H}_5$  with acetic acid. Plates. V. sol. alcohol, benzene, benzoline, and  $\text{CS}_2$  (Gabriel, *B.* 18, 2433).

**BENZYLIDENE-PHTHALIDE**  $\text{C}_{12}\text{H}_8\text{O}_2$  i.e.  $\text{C}_6\text{H}_4 < \text{C}(\text{CHPh}) > \text{CO}$ . [99°]. Benzylidene-phthalyl. Anhydride of decybenzoic carboxylic acid.

**Formation.**—1. By heating phthalic anhydride (5 pts.) with phenyl-acetic acid (5 pts.) and  $\text{NaOAc}$  (1 pt.) (Gabriel & Michael, *B.* 11, 1018).

K K

3. By heating phthalyl-phenyl-acetic acid *in vacuo* (Gabriel, *B.* 17, 2526).

**Preparation.**—A mixture of 100 g. phenyl-acetic acid, 110 g. phthalic anhydride and 2½ g. dry sodium acetate is heated for 2 hours, and the product crystallised from alcohol; the yield is 75–78 p.c. (Gabriel, *B.* 18, 3470).

**Properties.**—Long prisms (from alcohol); insol. water, sl. sol. cold alcohol.

**Reactions.**—1. Hot aqueous KOH forms potassium deoxybenzoin carboxylate. —2. By heating with alcoholic NH<sub>3</sub> at 100° it is converted into deoxybenzoin-*carboxylamide*  $C_6H_5 \cdot C(=CO \cdot CH_2 \cdot C_6H_5) \cdot CO \cdot NH_2$ , which by solution in H<sub>2</sub>SO<sub>4</sub> or by boiling with glacial acetic acid loses H<sub>2</sub>O giving benzylidene-phthalimidine (phthalimidyl-benzyl)  $C_6H_5 \cdot C(=C(=CH \cdot C_6H_5)) \cdot NH$ . —3. Simi-

larly *ethyl-amine* yields the ethyl-amide of deoxybenzoin-carboxylic acid, and this on boiling with acetic acid gives benzylidene-phthal-ethyl-imidine  $C_6H_5 \cdot C(=C(=CH \cdot C_6H_5)) \cdot NEt$  (Gabriel, *B.* 18, 2433). —4. By dissolving in benzene and treatment with nitrous acid gas it yields the compound  $C_6H_5 \cdot C(=C(NO_2) \cdot (CH(NO_2) \cdot C_6H_5)) \cdot O$  (Gabriel, *B.* 18, 1251).

**References.**—V. CYANO- and NITRO-BENZYLIDENE-PHTHALIDE.

#### Benzylidene-phthalide-di-bromide

$C_6H_5 \cdot CBr(=CHBr \cdot C_6H_5) \cdot O$ . [146°]. Formed by the combination of benzylidene-phthalide with bromine (Gabriel, *B.* 17, 2527). Thick glistening prisms. Sparingly soluble in alcohol.

(*iso*)-Benzylidene-phthalide  $C_{13}H_{10}O_2$  i.e.  $C_6H_5 \cdot C(=CH \cdot C_6H_5) \cdot CO$ . [91°]. Formed by reduction of nitro-benzylidene-phthalide

$C_6H_5 \cdot C(=C(NO_2) \cdot C_6H_5) \cdot O$  with HI and P. Prepared by reduction of nitro-benzylidene-phthalide; yield, 47 p.c. of the phenyl-acetic acid employed to prepare the benzylidene-phthalide (Gabriel, *B.* 18, 3471). Flat colourless needles. Easily soluble in alcohol and benzene, sparingly in ligroin. By further reduction with HI and P at 200° it yields *s*-di-phenyl ethane-*o*-carboxylic acid  $C_6H_5 \cdot CH_2 \cdot CH_2 \cdot C_6H_5 \cdot CO_2H$ . By boiling with aqueous NaOH it is converted into deoxybenzoin-*o*-carboxylic acid  $C_6H_5 \cdot (CO_2H) \cdot CH_2 \cdot CO_2 \cdot C_6H_5$ . Heated with alcoholic NH<sub>3</sub> it gives *iso*-benzylidene phthalimidine

$C_6H_5 \cdot C(=CHCO_2H) \cdot CO \cdot NH$  (Gabriel, *B.* 18, 2445).

#### BENZYLIDENE-PHTHAL-IMIDINE

$C_6H_5 \cdot ON$  i.e.  $C_6H_5 \cdot C(=C(=CH \cdot C_6H_5) \cdot CO) \cdot NH$ . *Phthalimidyl-benzyl*. [183°]. Yellow plates. Formed from the amide of deoxybenzoin-*o*-carboxylic acid  $C_6H_5 \cdot (CO \cdot NH_2) \cdot CO \cdot CH_2 \cdot C_6H_5$  by solution in H<sub>2</sub>SO<sub>4</sub> or by boiling with acetic acid (Gabriel, *B.* 18, 2433). V. also Bromo- and Nitro-BENZYLIDENE-PHTHALIMINE.

**Isobenzylidene-phthalimidine** *c.* (*l*y. 4)-Oxy-**(Py. 2)-FENYL-180QUINOLINE**.

#### BENZYLIDENE-DIPIPERIDINE

$C_6H_5 \cdot CH(C_6H_5 \cdot N_2)$ . [81°]. Formed by heating piperidine with benzoic aldehyde. Colourless prisms. Very unstable, being decomposed even by boiling with water. Dilute acids resolve it into benzoic aldehyde and piperidine (Laun, *B.* 17, 678).

#### BENZYLIDENE-RHODANIC ACID

$C_{10}H_7NS_2O$  i.e.  $C_6H_5 \cdot CH \cdot C(SH) \cdot CO \cdot S \cdot CN$ . [200°]. Formed by the action of benzoic aldehyde upon rhodanic acid in presence of dehydrating agents (Nencki, *B.* 17, 2278). Yellow needles, sol. water. By heating with baryta-water it is split up into  $\alpha$ -sulphhydro-cinnamic acid  $C_6H_5 \cdot CH \cdot C(SH) \cdot CO_2H$  and hydrogen sulphocyanide. Heated at 410° with conc. H<sub>2</sub>SO<sub>4</sub> (4 pts.) it is converted into benzylidene-rhodanic-oxy-sulphonic acid  $C_{10}H_7NS_2O_3$  (Ginsburg a. Bondzynski, *B.* 19, 119).

**BENZYLIDENE-RHODANIC-OXY-SULPHONIC ACID**  $C_{10}H_7NS_2O_3$ . Formed by heating benzylidene-rhodanic acid with conc. H<sub>2</sub>SO<sub>4</sub> (4 pts.) at 110°. Needles. V. sol. water and alcohol. Very strong acid (Ginsburg a. Bondzynski, *B.* 19, 119).

**BENZYLIDENE-ROSANILINE**  $C_{21}H_{15}N_3$ . From rosaniline and benzoic aldehyde by heat or by shaking with SO<sub>2</sub>Ac (Schiff, *A.* 140, 111; *Z.* 1867, 176). —B<sup>+</sup>. H<sub>2</sub>PtCl<sub>6</sub>.

**BENZYLIDENE-SELENIDE**  $C_6H_5CHSe$ . *Seleno-benzoic aldehyde*. [70°]. From benzylidene chloride and alcohol K<sub>2</sub>Se (Cole, *B.* 8, 1165). Yellow needles (from alcohol), insol. water. Not attacked by NH<sub>3</sub>.

**BENZYLIDENE-DI-SKATOLE**  $C_{21}H_{15}N_2$  i.e.  $PhCH(C_6H_5 \cdot N_2) \cdot (142^\circ)$ . From skatole (2½ pts.), benzoic aldehyde (1 pt.) and a little ZnCl<sub>2</sub> (Wenzing, *A.* 239, 241). Insol. water; v. sol. hot alcohol and ether. Boiling HCl does not split off benzoic aldehyde.

**BENZYLIDENE SULPHIDE** *v.* THIO-BENZOIC ALDEHYDE.

**BENZYLIDENE THIO-BIURET**  $C_{12}H_9N_2S_2$  i.e.  $C_6H_5 \cdot CH \cdot N(=C(SH)) \cdot NH(=C(SH))$ . [237°]. Formed by heating benzoic aldehyde with ammonium sulphocyanide at 137°–165° (Brodsky, *M.* 8, 27). Minute prisms (from alcohol); insol. water, sl. sol. cold alcohol; sol. dilute KOH. Boiling baryta-water forms benzoic aldehyde, barium sulphocyanide, and di-phenyl-thio-urea.

**Acetyl derivative**  $C_6H_5 \cdot Ac \cdot N_2S_2$ . [189°]. **BENZYLIDENE-*o*-TOLUIDINE**  $C_{11}H_9N$  i.e.  $C_6H_5 \cdot CH \cdot N \cdot C_6H_4 \cdot CH_3$ . [1:2]. *Benzaldehyde-*o*-toluide* (314°). From *o*-toluidine and benzoic aldehyde (Etard, *C. R.* 95, 730). Resolved by boiling water into its generators. By passing through a tube heated to dull redness it is converted into phenyl-indole  $C_6H_5 \cdot C(=CH) \cdot C_6H_4 \cdot NH$  (Picot, *B.* 19, 1063).

**Benzylidene-*p*-toluidine**  $C_{11}H_9N$  i.e.  $C_6H_5 \cdot CH \cdot N \cdot C_6H_4 \cdot CH_3$ . [1:4]. From benzoic aldehyde and *p*-toluidine at 100° (Schiff, *A.* 140, 96; Kohler, *A.* 241, 359; Mazzara, *G.* 10, 370). Melts below 100°, but changes at 160° into an *isomeride* [120°–125°]. —B<sup>+</sup>. H<sub>2</sub>PtCl<sub>6</sub>.

**DI-BENZYLIDENE-TOLYLENE-DIAMINE**  $C_{22}H_{17}N_2$  i.e.  $C_6H_5 \cdot Me(N \cdot CH) \cdot (1:2:4)$  [122°–128°]. From benzoic aldehyde and tolylene-diamine at 100° (Schiff, *A.* 140, 98). **Neutral**

# BENZYL-METHYL-ACETO-ACETIC ACID.

469

crystalline mass; at 140°-180° it gives amarine.

**BENZYLIDENE-DI-UREA**  $C_6H_5N_2O_2$ , i.e.  $C_6H_5CH(NH.CO.NH)_2$ . *Benzaldehyde di-ureide* [195°]. Formed by adding benzoic aldehyde to an alcoholic solution of urea (Schiff, A. 151, 192). Crystalline powder, insol. water and ether, sol. alcohol.

**Di-benzylidene-tri-urea**  $C_{12}H_{15}N_3O_3$ . Powder, formed by heating urea with benzoic aldehyde.

**Tri-benzylidene-tetra-urea**  $C_{18}H_{21}N_4O_4$  [c. 240°]. Powder, formed by heating benzylidene-di-urea with benzoic aldehyde.

**BENZYLIDENE DI-URETHANE** v. **BENZYLIDENE-DI-CARBAMIC ACID**.

**BENZYL-INDOLE**  $C_{11}H_9N$  i.e.

$C_6H_5\langle\begin{smallmatrix} CH \\ NC.H \end{smallmatrix}\rangle CH$ . [145°]. From its carboxylic acid (q. v.) by heat. Yellowish needles (from alcohol). V. sol. benzene, light petroleum, chloroform and ether. Turns pine wood moistened with HCl yellow. Picrate forms red needles.

**BENZYL-INDOLE CARBOXYLIC ACID**

$C_{11}H_9NO_2$ , i.e.  $C_6H_5\langle\begin{smallmatrix} CH \\ NC.H \end{smallmatrix}\rangle S.CO_2H$ . [195°, with decomposition]. Pyruvic acid combines at 16° with benzyl-phenyl-hydrazine, forming  $*CH_2.C(CO.H).N.NPh.C.H$ , whence HCl at 100° forms benzyl-indol-carboxylic acid (Antrick, A. 227, 362).

*Properties.*—Colourless needles (from glacial acetic acid). Sl. sol. water, chloroform, and petroleum, sol. ether and alcohol, v. sl. sol. benzene. Converted by heat into  $CO_2$  and benzyl indole.

**BENZYL IODIDE**  $C_6H_5I$  i.e.  $C_6H_5.CH_2I$ . [24°]. S.G. 2.173.

*Formation.*—1. From benzyl alcohol in CS<sub>2</sub> and iodide of phosphorus. 2. Slowly formed by the action of cold HI (S.G. 1.96) on benzyl chloride (Lieben, Z. 31, 6, 736).—3. From benzyl chloride and KI (V. Meyer, B. 10, 311; Kumpf, A. 224, 126),  $ZnI_2$  or  $PbI_2$  (Brix, A. 225, 154).

*Properties.*—Crystals; decomposed by distillation. Gives benzyl acetate with  $AgOAc$ , and tribenzylamine with alcoholic  $NH_3$ . Silver nitrite gives benzoic aldehyde and acid (Van Rensse, B. 9, 1454; Brunner, B. 9, 1741).

**BENZYL- (pseudo)-ISATIN**  $C_{11}H_9NO_2$ , i.e.  $C_6H_5\langle\begin{smallmatrix} CO \\ NC.H \end{smallmatrix}\rangle CO$ . [131°]. From benzyl-indole carboxylic acid and NaOCl in feebly alkaline solution, the insoluble chloride then produced being subsequently boiled with alcoholic NaOH (Antrick, A. 227, 365).

*Properties.*—Slender needles (from alcohol). Sl. sol. water, sol. ether. Shows the indophenine reaction with  $H_2SO_4$  and crude benzene containing thiophene.

**DI-BENZYL-KETONE**  $C_{12}H_{10}O$  i.e.  $CO(CH_2Ph)_2$ . *Di-phenyl-acetone*. Mol. w. 210. [30°]. (320°). Formed by the dry distillation of barium phenyl-acetate. Prisms.  $CrO_3$  oxidises it to benzoic and acetic acids (Popoff, B. 6, 560). Reduced by HI at 180° to di-benzyl-methane (Graebe, B. 7, 1623).

**BENZYL-MALONIC ACID**  $C_{10}H_8O_4$ , i.e.  $C_6H_5.CH_2.CH(CO_2H)_2$ . *Phenyl-isosuccinic acid*. [117°].

*Formation.*—1. By saponification of its ether.

2. From benzylidene-malonic acid by sodium-amalgam.

*Properties.*—Triolinic crystals, sol. water, alcohol, and ether. Splits up at 180° into  $CO_2$  and  $\beta$ -phenyl-propionic acid.

*\* Ethyl ether Et.A.* (300°). S.G. 1.08 (Conrad, A. 204, 174; B. 12, 752). Sodium benzyl-malonic ether is converted by iodine dissolved in ether into  $*C_6H_5.CH_2.Cl(CO_2Et)_2$ , which is converted by alcoholic KOH into ethoxy-benzyl-malonic ether (Bischoff a. Hausdörfer, A. 239, 110). Converted by alcoholic  $NH_3$  into the amides  $CH_2Ph.CH_2(CONH_2)_2$  [225°] and  $CH_2Ph.CH_2(CO_2Et)(CONH_2)$  [98°] (Bischoff a. Siebert, A. 239, 96).

**Di-benzyl-malonic acid**  $(C_6H_5.CH_2)_2C(CO_2H)_2$ . [172°]. P.; [163°] (B. a. H). Formed by saponifying the ether (Perkin, C. J. 47, 821). Slender needles (from water) or thick prisms (from alcohol). V. e. sol. ether and alcohol, m. sol. hot water, sl. sol. hot ligroin. Gives di-benzyl-acetic acid on heating.

*Ethyl ether*  $(C_6H_5.CH_2)_2C(CO_2Et)_2$ . (250°) at 40 mm. S.G. 3° = 1.093. Thick yellow liquid. Formed by the action of benzyl chloride upon sodio-malonic ether. By heating with alcoholic KOH it is converted into di-benzyl-acetic acid (Lellmann a. Schleich, B. 20, 439). Converted by treatment with alcoholic ammonia into  $CO_2Et.CH_2(C_6H_5)_2.CO.NH_2$  and  $(CO.NH_2).CH_2CH_2Ph$ , benzyl being split off (Bischoff a. Siebert, A. 239, 97).

**Tri-BENZYL-MELAMINE**

$(C_6H_5.CH_2.NH.CN)_3$ . Formed spontaneously from benzyl-cyanamide by isomeric change (Strakosch, B. 5, 694).—B<sup>3</sup>3HCl.

**BENZYL-MERCAPTAN**  $C_6H_5SH$  i.e.

$C_6H_5.CH_2.SH$ . Mol. w. 124. (195°). S.G. 1.958. From benzyl chloride and KHS in alcohol (Mareker, A. 136, 75; 140 86) Pungent liquid with alliaceous odour.

*Salts.*— $(C_6H_5S)_2Hg$ ; needles.— $C_6H_5SHgCl$ .— $(C_6H_5S)_2Pb$ .

*Benzoyl derivative*  $C_6H_5.CH_2.SBz$ . [40°]. Colourless crystals (Otto a. Lüders, B. 13, 1285).

*Ethyl derivative*  $C_6H_5.SEt$ . (216°).

**BENZYL-MESITYLENE**  $C_{14}H_{12}$ , i.e.

$C_6H_5.CH_2.C_6H_3Me_3$ . [36°]. (c. 302). V.D. 7.35. Prepared by boiling benzyl chloride with mesitylene in presence of  $AlCl_3$  (Louise, A. Ch. [6] 6, 176, C. R. 95, 1163). Prisms; v. sol. alcohol, ether, and benzene.

*Reactions.*—1. HI at 180° gives toluene and mesitylene.—2.  $CrO_3$  gives benzoyl-mesitylene. 3.  $HNO_3$  forms a tri-nitro-derivative, [185°] and an acid [266°].—4. Passage through a red-hot tube forms two di-methyl-anthracenes, anthracene, and phenanthrene.

**Di-benzyl-mesitylene**  $(C_6H_5.CH_2)_2C_6H_3Me_3$ . [137°]. (355°) at 120 mm. From benzyl-mesitylene, benzyl chloride, and  $AlCl_3$  (Louise, A. Ch. [6] 6, 197). Minute prisms.

**BENZYL-METHANE** v. **ETHYL-BENZENE**.

**Di-benzyl-methane** v. **DI-PHENYL-PROPANE**.

**BENZYL MUSTARD OIL** v. **BENZYL THIO-CARBIMIDE**.

**BENZYL-METHYL-ACETIC ACID** v. **PHENYL-ISO-BUTYRIC ACID**.

**BENZYL-METHYL-ACETO-ACETIC ACID** v. p. 25.

**BENZYL-DI-METHYL-AMINE**  $C_8H_{11}N$  i.e.  $C_6H_5CH_2NMe_2$ . *Di-methyl-benzylamine*. (184°). From benzyl chloride and alcoholic dimethylamine (Schotten, *B.* 15, 424; Jackson & Wing, *Am.* 9, 78). Oil, miscible with alcohol and ether.

**Salts.**— $B^+HCl^-$ — $B^+HNO_2^-$ — $B^+H_2PtCl_6^-$ — $B^+H_2FeCl_6^-$ — $B^+H_2ZnCl_4^-$ .

*Methylo-chloride*  $B^+MeCl^-$ : white crystals, sol. water, v. sl. sol.  $Na_2CO_3$ ,  $Aq.$ —( $B^+MeCl$ ),  $PtCl_4$ .

**BENZYL-TETRA-METHYL-BENZENE**  $C_{12}H_{18}$ ,  $C_{12}H_{18}Me_4$  [1:2:3:4:6]. [61°]. (c. 310°). From benzoyl-iso-durene and fuming  $HNO_3$  at 250° (Essner & Gossin, *Bl.* [2] 42, 170; *A. Ch.* [6] 1, 516).

**BENZYL-METHYL-CARBINOL**  $C_8H_9CH_2CH(OH)CH_3$ . (215° i. V.). From benzyl methyl ketone and sodium-amalgam (Errera, *G.* 16, 315).

**BENZYL-METHYL-GLYOXIM**  $C_{10}H_{12}N_2O_2$  i.e.  $C_6H_5CH_2C(NO)(OH)C(NO)(OH)CH_3$ . [181°]. Formed by the action of hydroxylamine hydrochloride on isonitroso-benzyl-acetone (Schramm, *B.* 16, 180). Small white needles. Sol. alcohol and ether. Sublimable. Weak acid.

*Di-acetyl-derivative*  $C_{10}H_{10}(NOAc)_2$ —[80°], small white crystals (Schramm, *B.* 16, 2188).

**BENZYL-METHYL-KETONE**  $C_{12}H_{16}O$  i.e.  $C_6H_5CH_2COCH_3$ . *Phenyl-acetone*. (215°). S.G. 1.010. Produced, together with acetone and di-benzyl-ketone, by distilling calcium acetate with calcium phenyl-acetate (Otto, *J. pr.* [2] 1, 141). Unites with  $NaHSO_3$ . By heating with conc.  $H_2SO_4$  on the water-bath it is converted into the sulphonic acid  $C_6H_5(SO_3H)CH_2COCH_3$ ; but by heating quickly to a higher temperature it is split up into  $\omega$ -toluene-sulphonic acid  $C_6H_4CH_2SO_3H$  and acetic acid (Krekeler, *B.* 19, 2625).

**BENZYL-METHYL-KETONE SULPHONIC ACID**  $C_6H_5(SO_3H)CH_2COCH_3$ . Formed by the action of fuming sulphuric acid upon benzyl methyl ketone in the cold.— $PbA'$  (Krekeler, *B.* 19, 2625).

**BENZYL-METHYL-MALONIC ACID**  $C_{11}H_{12}O_4$  i.e.  $C_6H_5CH_2CMe(CO_2H)_2$ . [135°]. Colourless crystals. Prepared from the ether. On heating it gives  $CO_2$  and phenyl-iso-butyric acid.

*Di-ethyl-ether*  $A^+Et_2$ . (300°). S.G.  $\frac{100}{15} = 1.061$ . Prepared by the action of benzyl chloride on sodio-methyl-malonic ether or of methyl iodide on sodio-benzyl-malonic ether (Conrad & Bischoff, *B.* 13, 593; *A.* 204, 177).

**BENZYL-METHYL OXIDE**  $C_8H_9CH_2OCH_3$ . (170°). From benzyl chloride and KOMe (Calours, *C. R.* 80, 1317).

**BENZYL-METHYL-PIPERIDINE**  $C_8H_9N(CH_2)_5CH_3$ . (245°). Colourless fluid. Formed by dry distillation of the alkaline hydrate produced by the action of moist  $Ag_2O$  on benzyl-piperidine-methylo-iodide.—( $B^+HCl$ ),  $PtCl_4$  (Schotten, *B.* 15, 423).

**DI-BENZYL-METHYL-(pseudo)-THIO-UREA**  $C_{12}H_{14}N_2S$  i.e.  $CH_3S \cdot C \cdot NH \cdot C_6H_5$ . Formed by heating di-benzyl-thio-urea with methyl iodide at 100°. Oil. V. sol. alcohol and ether, insol. water.

**Salts.**— $B^+HCl^-$ —[150°]; easily soluble large rhombic four-sided tables.— $B^+H_2SO_4^-$  [145°]; glistening needles; v. sol. water and alcohol.— $B^+HI^-$  [99°]; octahedra; v. sol. warm alcohol, sl. sol. hot water.— $B^+H_2ClPtCl_6^-$ ; sparingly soluble four-sided prisms (Reimarus, *B.* 19, 2348).

(a)-**BENZYL-NAPHTHALENE**  $C_{17}H_{14}$  i.e.  $C_6H_5CH_2C_{10}H_8$ . [59°]. (c. 330°). S.G.  $\frac{12}{15} = 1.166$ . S. (alcohol) 33 at 78°; S. (ether) 50 at 15°. From naphthalene, benzyl chloride, and zinc dust (Froté, *C. R.* 76, 639; Miquel, *Bl.* [2] 26, 2). Monoclinic prisms. Dilute  $HNO_3$  produces phenyl (a)-naphthyl ketone [75°].

*Sulphonic acid*  $C_{17}H_{13}SO_3H$ — $KA'$  aq: needles (from alcohol).

(b)-**Benzyl-naphthalene**  $C_{17}H_{14}$ . [55°]. (c. 315°). S.G.  $\frac{1}{15} = 1.176$ . S. (alcohol) 2.25 at 15°. Formed, together with the preceding, by heating naphthalene with benzyl chloride and  $AlCl_3$  (Vincent & Roux, *Bl.* [2] 40, 163). Monoclinic prisms (from alcohol); v. e. sol. benzene and chloroform. Nitric acid produces phenyl (b)-naphthyl ketone [82°].

**BENZYL-(a)-NAPHTHYLAMINE**

$C_{17}H_{15}NH_2$ ,  $C_{17}H_{15}N$ . [67°]. From naphthylamine and benzyl chloride (Froté & Tommasi, *Bl.* [2] 20, 67).

**BENZYL-NAPHTHYL-KETONE**  $C_{17}H_{14}O$  i.e.  $C_6H_5CH_2CO \cdot C_{10}H_8$ . [57°]. Tables. Prepared by the action of  $AlCl_3$  on a mixture of phenyl-acetyl chloride and naphthalene. On reduction with  $HI$  it gives phenyl-naphthyl-ethane (Graebe & Bungeener, *B.* 12, 1078).

**BENZYL-NAPHTHYL-METHANE** v.

PHENYL-NAPHTHYL-ETHANE.

**BENZYL-(b)-NAPHTHYL OXIDE**

$C_{17}H_{14}O$ ,  $C_{17}H_{14}O$ . [99°]. White plates. Prepared by the action of benzyl chloride on sodium-(b)-naphthol (Staedel, *B.* 14, 899; *A.* 217, 47).

• **BENZYL-NARCEINE** v. NARCEINE.

**BENZYL-NITRATE**  $C_8H_9CH_2NO_3$ . Is perhaps formed by the action of benzyl chloride on  $AgNO_3$  (Brunner, *B.* 9, 1745).

**BENZYL-NITRO-ARBUTIN** v. p. 298.

**BENZYL-NITRO-PHENYL** v. NITRO-PHENYL-BENZYL.

**BENZYL-ISO-NITROSO-MALONIC ACID**

$C_8H_9CH_2ON:C(CO_2H)_2$ . From its ether. The potassium salt on dry-distillation gives KCN, potassium carbonate and benzyl alcohol.

*Di-ethyl ether*  $A^+Et_2$ . Prepared by the action of benzyl chloride and sodium ethylate on iso-nitroso-malonic ether (Conrad & Bischoff, *B.* 13, 593).

**BENZYL-NITROSO-MALONYL-UREA** v.

*Benzyl ether of VIOLIC ACID*.

**BENZYL-OXALATE**  $C_{12}H_{10}O_4$  i.e.

$(C_6H_5CH_2)_2C_2O_4$ . [81°]. From benzyl chloride and silver oxalate (Beilstein & Kuhlberg, *A.* 147, 341). Scales (from alcohol); may be distilled.

**BENZYL OXAMATE**  $C_8H_9NO_3$

i.e.  $NH \cdot CO \cdot CO_2CH_2Ph$ . [135°]. From  $NH_4CCl_2CO_2CH_2Ph$  and benzyl alcohol (Wal-lach & Liebmann, *B.* 13, 507).

**DI-BENZYL OXAMIDE**  $C_{12}H_{14}N_2O_2$  i.e.  $C_6O_2(NHCH_2Ph)_2$ . [216°]. From oxalic ether and benzylamine; or by boiling benzylamine cyanide with  $HCl$  (Strakosch, *B.* 5, 694). Scales (from alcohol).

**BENZYL-OXANTHRANOL** v. OXANTHRANOL.

## TETRA-BENZYL-OXY-AMMONIUM IODIDE

v. HYDROXYLAMINE.

BENZYL-OXY-BENZOIC ACID v. OXY-

BENZYL-BENZOIC ACID.

BENZYL-OXY-BUTYRIC ACID v. OXY-

PHENYL-VALERIC ACID.

BENZYL-OXY-MALONIC ACID v. BENZYL-

TARTARIC ACID.

BENZYL-OXY-SULPHIDE v. DI-BENZYL

SULPHOXIDE.

**BENZYL-PHENANTHRENE**  $C_{21}H_{18}$ , i.e.  $CH_2Ph.C_{10}H_7$ . [156°]. From benzyl chloride, phenanthrene (*q.v.*) and zinc-dust (Goldschmiedt, *M.* 2, 444). Needles (from benzene).  $CrO_3$  gives benzoic acid and phenanthraquinone.

**p-BENZYL-PHENOL**  $C_{12}H_{10}O$  i.e.  $C_6H_5.CH_2.C_6H_4.OH$  [1:4]. *Oxy-di-phenyl-methane*. Mol. w. 184. [84°]. (325°-330°).

**Formation**.—1. From phenol, benzyl chloride and zinc-dust (Paterno, *G.* 2, 2; 3, 121).—2. From benzoyl-anisol and HI (Paterno, *B.* 5, 288; 6, 1202).—3. From  $PhOAc$  and  $C_6H_5.CH_2Cl$  alone or with  $AlCl_3$ , and saponification of the product (Perkin, jun., a. Hodgkinson, *C. J.* 37, 722; Rennie, *C. J.* 41, 228).—4. By heating phenol with benzyl alcohol and  $ZnCl_2$  (Liebmann, *B.* 15, 152).—5. By diazotising *p*-amido-di-phenyl-methane and treating the product with water (Basler, *B.* 16, 2719).

**Properties**.—Long needles or plates (from alcohol). Sol.  $KOH$  aq but not  $NH_4Aq$ .

**Reactions**.—1. Distilling with  $P_2O_5$  gives benzoic acid, phenol, and anthracene.—2. By *bromination* and *nitration*, or by *nitration* and *bromination* it gives the same bromo-nitro-derivative, when treated with  $HNO_3$  in  $C_2H_5O_2$  forms  $C_6H_5(OH)(NO_2)Br$  [1:2:4:6]. Hence the bromo-nitro-derivative  $C_6H_5(OH)(C_6H_5)(NO_2)Br$  is either (1:2:4:6) or (1:4:2:6). But the oxidation of  $C_6H_5.CH_2.C_6H_4.OMe$  to  $C_6H_5.CO.C_6H_4.OMe$  [1:4] shows that the arrangement is (1:2:4:6).—3. Phosphorus pentachloride forms  $(C_6H_5)_3PO$  [94°].—4. Chloro-acetic acid and  $KOH$  convert benzyl-phenol into  $CH_2Ph.C_6H_4.OCH_2.CO_2H$  [100°], while  $CH_2Ph.CHCl.CO_2H$  and  $KOH$  give rise to  $CH_2Ph.C_6H_4.OCHMe.CO_2H$  [102°] (Mazars, *G.* 11, 437; 12, 262).

**Methyl derivative**  $C_6H_5.CH_2.C_6H_4.OMe$ . **Benzyl-anisol**. (305°). From anisol, benzyl chloride, and zinc. Oxidised by alkaline  $KMnO_4$ , it gives the methyl derivative of *p*-benzoyl-phenol.

**Acetyl derivative**  $Ph.CH_2.C_6H_4.OAc$ . (315°-320°).

**Benzoyl derivative**  $Ph.CH_2.C_6H_4.OBz$ . [86°].

**Sulphonic acid**  $C_6H_5.CH_2(SO_3H)(OH)$ .

**Salts**.— $NH_4Aq$ : needles.  $KA$ : feathery crystals.  $BAa$ :  $C_6H_5SO_3Ba$ : minute crystals. These salts are all sparingly soluble (Rennie, *C. J.* 41, 34; 49, 406). They, as well as the free acid, give a violet colour with  $FeCl_3$ .

**p-BENZYL-DIPHENYL**  $C_{18}H_{16}$ , i.e.

$C_6H_5.CH_2.C_6H_4.C_6H_5$ . [85°]. (286°) at 100 mm. By heating benzyl chloride and diphenyl with zinc dust at 100° two benzyl-diphenyls are produced together with traces of anthracene. The *p*-hydrocarbon is less soluble and solidifies more easily than its isomeride (Goldschmiedt, *M.* 2, 433). Leaflets or needles, m. sol. alcohol, v. sol. benzene and ether.  $CrO_3$  oxidises it, to

phenyl-benzophenone and benzophenone *p*-carboxylic acid.

**o-Benzyl-diphenyl (?)**. [84°]. (c. 285°) at 110 mm. Prepared as above. Monoclinic needles.  $CrO_3$  oxidises it completely.

**Di-benzyl-diphenyl**  $C_{18}H_{16}(CH_2Ph)_2$ . [118°]. From di-benzoyl-diphenyl and HI at 170° (Wolf, *B.* 14, 2032). Laminæ (from alcohol).

**BENZYL-PHENYL** v. PHENYL-BENZYL.

**BENZYL-DIPHENYL-AMINE** v. DI-PHENYL-

BENZYL-AMINE.

**u-DI-BENZYL-p-PHENYLENE-DIAMINE**

$C_{18}H_{18}(NH_2)_2.N(CH_2C_6H_5)_2$  [1:4]. *Amido-di-benzyl-aniline*. [90°]. Obtained by reduction of *p*-nitro-di-benzyl-aniline with tin and  $HCl$ . Glistening colourless needles. V. sol. ether and hot alcohol, sl. sol. cold alcohol. With  $FeCl_3$  it gives a deep-red colouration, with  $FeCl_4$  and  $H_2S$  a blue insoluble pp. By conc.  $HCl$  at 170° it is completely resolved into benzyl chloride and *p*-phenylene-diamine.

**Benzaldehyde compound**

$C_6H_5.CH_2(OH).NH.C_6H_5.N(CH_2C_6H_5)_2$ . [130°]. Microcrystalline yellow pp. V. sol. benzene, sl. sol. ether, insol. alcohol (Matzuda, *B.* 20, 1614).

**BENZYL-PHOSPHINE**  $C_6H_5P$  i.e.

$C_6H_5.CH_2.PH_2$ . (180°). From benzyl chloride,  $PH_3I$ , and  $ZnO$  (Hofmann, *B.* 5, 100). Oil, volatile with steam.  $BHI$ : decomposed by water into its components.

**Benzyl-triethyl-phosphonium chloride**

$PEt_3(CH_2Ph)Cl$ . From benzyldiene chloride, tri-ethyl-phosphine and alcohol (Hofmann, *A. Suppl.* 1, 323).

**Di-benzyl-phosphine**  $(CH_2Ph)_2PH_2$ . [205°].

Prepared together with the preceding, and separated by steam-distillation, not being volatile. Groups of needles (from alcohol); insol. acids.

**Tri-benzyl-phosphine**  $P(CH_2Ph)_3$ . Appears to be formed as a by-product in the action of benzyl chloride on  $PNa_3$  (Letts a. Collie, *Tr. E.* 30, 181). Splits up on distillation into phosphorus, *s*-di-phenyl-ethylene, dibenzyl, and toluene.

**Tri-benzyl-phosphine oxide**  $(CH_2Ph)_3PO$ .

[213°]. Formed by heating  $PH_3I$  with benzyldiene chloride at 130° and boiling the product with alcohol (Fleissner, *B.* 13, 1665). Formed also by the action of conc.  $Ba(OH)_2$  on tetra-benzyl-phosphonium acid sulphate; a weak solution of baryta giving  $P(C_6H_5)_3OH$  (Letts a. Collie, *Tr. E.* 30, 181). Needles; insol. water, sol. alcohol and ether.  $(C_6H_5)_3PCl_2.HgCl_2$ . —  $(C_6H_5)_3PO_2FeCl_3$ . —  $(C_6H_5)_3PO_2CoCl_2$ . —  $(C_6H_5)_3PO_2PdCl_2$ . —  $(C_6H_5)_3PO_2PtCl_2$ . —  $(C_6H_5)_3PO_2ZnBr_2$ . —  $(C_6H_5)_3PO_2S$ .

**Tri-benzyl-phosphine sulphide**  $(CH_2Ph)_3PS$ .

[206°]. Obtained by distilling the acid sulphate of tetra-benzyl-phosphonium (Letts a. Collie). Long thin needles, m. sol. alcohol.

**Tetra-benzyl-phosphonium hydroxide**

$P(C_6H_5)_4OH$ . [over 200°]. Obtained by adding  $BaCO_3$  to the sulphate. Rhombohedral plates; v. sol. water and alcohol; alkaline to litmus. Decomposed by heat into  $P(C_6H_5)_3O$  and toluene.

**Tetra-benzyl-phosphonium salts.**

**Chloride**  $P(CH_2Ph)_4Cl$ . [224°]. From benzyl chloride and  $PNa_3$  (L. a. C.). Crystallises from water with 2aq, and from chloroform with  $CHCl_3$ . Split up by heat into tri-benzyl-phosphine, *s*-di-phenyl-ethylene, and  $HCl$ .

**Platinochloride**  $\{P(CH_2Ph)_4\}_2PtCl_6$ .

**Sulphates.**— $\{P(C_6H_5)_3\}_2SO_4$ : [320°]. —  $2(C_6H_5)_3SO_4H$ : [217°].

**Oxalate**  $P(C_6H_5)_3.C_2O_4H$ : needles.

**BENZYL-ISO-PHTHALIC ACID**  $C_{11}H_{10}O_4$ , *i.e.*  $C_6H_5.CH_2.C_6H_4(CO_2H)_2$ . [243°]. From benzyl-iso-phthalic acid by reduction with sodium-amalgam (Zincke, *B.* 9, 1765). Crystalline powder, v. sl. sol. water. —  $BaA''$ . —  $CaA''$  aq.

**Benzyl-terephthalic acid**

$C_6H_5.CH_2.C_6H_4(CO_2H)_2$ . Obtained by reduction of benzyl-terephthalic acid (Weber, *J.* 1878, 403). —  $BaA''$ .

**BENZYL-PHTHALIMIDINE**  $C_{11}H_{11}ON$ , *i.e.*

$C_6H_5 \begin{array}{c} \diagup CH \\ \diagdown CO \end{array} \begin{array}{c} \diagup CH_2.C_6H_5 \\ \diagdown NH \end{array}$  [137°]. Colourless

plates or scales. Formed by reduction of benzyl-idenophthalimidine by means of  $H_2$ .

**Nitrosamine**  $C_6H_5 \begin{array}{c} \diagup CH \\ \diagdown CO \end{array} \begin{array}{c} \diagup CH_2.C_6H_5 \\ \diagdown N(NO) \end{array}$

[93°]; yellow crystals, easily soluble in benzene, ligroin, and chloroform (Gabriel, *B.* 18, 1262).

**BENZYL-PHTHALIMIDE**

$C_6H_5.C_6H_4.N.CH_2.C_6H_5$ . *Phthalyl-benzylamine*. [116°]. Long needles. Obtained by heating potassium phthalimide with benzyl chloride at 170°–180°.  $HCl$  at 200° splits it up into phthalic acid and benzylamine (Gabriel, *B.* 20, 2237).

**BENZYL-PIPERIDINE**  $C_{11}H_{15}N(C_6H_5)$ . (245°). Colourless liquid. Insol. water. Prepared by the action of benzyl chloride on piperidine. —  $(B'HCl).PtCl_4$ : sparingly soluble pp.

**Methyl-iodide**  $B'MeI$ . [145°]. Thick prisms. By moist  $AgO$  it gives an alkaline hydrate which on dry-distillation yields methyl-benzyl-piperidine (Schotten, *B.* 15, 423).

**BENZYL PROPIONATE**  $C_{10}H_{11}O_2$ , *i.e.*

$C_6H_5.CH_2.O.CO.CH_2.CH_3$ . (220°). S.G.  $1.0360$ . Decomposed by  $Na$  into sodium propionate and benzyl phenyl-butyrate (Conrad & Hodgkinson, *A.* 193, 320).

***v.* BENZYL-PYRROL**  $C_8H_9.N.C_6H_5$ . (217° uncorr.). Colourless crystalline solid. Melts when touched with the hand. V. sol. alcohol and ether, nearly insol. water (Ciamician & Silber, *B.* 20, 1369).

***v.* BENZYL-PYRROLENE DI-METHYL-DI-KETONE**  $C_8H_7(CO.CH_3)_2.NC_6H_5$ . *v.* *Benzyl-di-acetyl-pyrrol*. [130°]. Formed by heating *v.* benzyl pyrrol with  $Ac_2O$  at 210°. Colourless plates. Sol. ether and benzene, s. sol. water, nearly insol. petroleum-ether (Ciamician & Silber, *B.* 20, 1370).

**BENZYL-QUINOLINIUM HYDROXIDE** *v.* *Benzyl-hydroxide of QUINOLINE*.

**BENZYL-ROSANILINES**. From rosaniline and benzyl chloride (Dahl, *D. P. J.* 263, 393); *v.* *ROSANILINE*.

**Methyl-iodide**. From rosaniline,  $MeI$  and  $MeOH$  (Hofmann, *B.* 6, 263).

**BENZYL SELENIDE**  $(C_6H_5.CH_2)_2Se$ . [40°]. From benzyl chloride and  $P_2Se_3$  (C. L. Jackson, *A.* 173, 1). Long needles or prisms (from alcohol); faint odour, insol. water, v. sol. alcohol and ether.  $HNO_3$  forms 'selenobenzyl nitrate' [88°]. —  $\{C_6H_5\}_2Se.PtCl_4$ .

**Benzyl diselenide**  $(CH_2Ph)_2Se_2$ . [90°]. Formed by boiling  $Na_2Se_2$ , benzyl chloride, and alcohol for some hours (*J.*). Unctuous yellow

scales (from alcohol). With  $MeI$  it forms  $(CH_2Ph)_2SMe_2I$ , [85°] from which may be obtained  $\{CH_2Ph\}_2SMe_2Cl.PtCl_4$ . Conc.  $HNO_3$  forms toluene-exo-selenic acid,  $C_6H_5.CH_2SeO_2H$ .

**BENZYL SELENO-CYANIDE**  $C_6H_5.NSe$ , *i.e.*  $C_6H_5.CH_2.SeCy$ . [72°]. From benzyl chloride and potassium selenocyanide (Jackson, *B.* 8, 321). Prismatic needles with repulsive odour; insol. water, v. sol. hot alcohol.  $HNO_3$  forms  $C_6H_5(NO_2).CH_2.SeCy$  [123°].

**BENZYL-SELEN-UREA**  $C_8H_9.N_2Se$ , *i.e.*  $NH_4.CSe.NH.CH_2Ph$ . [70°]. From benzylamine hydrochloride and alcoholic potassium selenocyanide (Spica, *G.* 7, 90). Sol. water, alcohol, and ether, gradually depositing  $Se$ . Conc.  $HCl$  forms benzylamine,  $Se$ , and  $HCN$ .

***u.* di-benzyl-seleno-urea**  $NH_4.CSe.N(CH_2Ph)_2$ . [150°]. From dibenzylamine hydrochloride and  $KSeCy$ . Thin prisms or needles; v. sol. hot water, alcohol, and ether. Conc.  $HCl$  forms  $Se$ ,  $CNH$ , and dibenzylamine.

**TETRA-BENZYL-SILICANE**  $C_{24}H_{20}Si$ , *i.e.*  $Si(CH_2Ph)_4$ . *Silicon-tetra-benzyl*. [128°]. (above 550°). S.G.  $2.1078$ . Formed by the action of sodium upon a mixture of benzyl chloride and  $SiCl_4$ , with addition of a little acetic ether (Polis, *B.* 18, 1543; 19, 1023). Large monosymmetrical prisms, sol. ether, benzene, and chloroform, sl. sol. alcohol. May be distilled.

**BENZYL SULPHIDE**  $C_6H_5.H_2S$ , *i.e.*  $(CH_2Ph)_2S$ . [50°]. From benzyl chloride and alcoholic  $K_2S$  (Märcker, *A.* 136, 88). Thick trimetric tablets (from ether), *a:b:c* = 813:1:515 (Forst, *A.* 178, 370; Bodewig). On distillation it gives *s.*-di-phenyl-ethylene and its sulphide (Barbier, *C. R.* 78, 1772), toluene, benzyl mercaptan, *s.*-di-phenyl-acetylene sulphide  $SC_6H_5$ , and thionessal  $C_2H_5.S$ .  $MeI$  forms  $SMe_2I$ , benzyl iodide and  $(CH_2Ph)SMe_2I$ ; the latter gives rise to the compound  $\{(CH_2Ph)SMe_2CH_2\}_2PtCl_4$ . Ethyl iodide at 100° forms similarly  $(C_2H_5)SEt_2I$  whence  $\{(C_2H_5)SEt_2Cl\}_2PtCl_4$  (Schöeller, *B.* 7, 1274; cf. Cahours, *A. Ch.* [5] 10, 21).

**DI-BENZYL DI-SULPHIDE**  $(C_6H_5.CH_2)_2S_2$ . *Sulphobenzol*. [70°].

**Formation.**—1. By the action of an alcoholic solution of  $KHS$  or  $K_2S$  on benzyldiene dichloride. —2. By the action of alcoholic  $KHS$  on (*a*)-thiobenzoic aldehyde (Klinger, *B.* 15, 861). —3. By the oxidation of benzyl mercaptan by air or bromine (Märcker, *A.* 140, 86). —4. By the action of  $K_2S_2$  on benzyl chloride in alcohol (*M.*).

**Properties.**—White plates. Gives a crystalline pp.  $(C_6H_5)_2S_2AgNO_3$  with an alcoholic solution of  $AgNO_3$ .

**BENZYL-SULPHINIC ACID** *v.* **TOLUENE EXO-SULPHINIC ACID**.

**BENZYL SULPHOCYANIDE**

$C_6H_5.CH_2.S.CN$ . [41°] (*B.*); [38°] (*H.*); (*a.* 233°) (*B.*); (256°) (*H.*). From benzyl chloride and alcoholic potassium sulphocyanide (Henry, *B.* 2, 636; Barbaglia, *B.* 5, 639). Prisms (from alcohol), insol. water; pungent smell. Combines with  $HBr$ , forming a compound decomposed by water. Fuming nitric acid forms  $C_6H_5(NO_2).CH_2.S.Cy$ .

**DI-BENZYL-SULPHONE**  $C_{12}H_{10}SO_2$ , *i.e.*  $(CH_2Ph)_2SO_2$ . [150°].

**Formation.**—1. Together with  $C_6H_5.CH_2.SO_2K$  by the action of  $K_2SO_4$  on benzyl chloride (Vogt & Henninger, *A.* 165, 375). —2. By oxida-

## BENZYL XYLYL KETONE.

tion of di-benzyl sulphoxide with  $\text{KMnO}_4$  and  $\text{HOAc}$  (Otto a. Ladders, *B.* 13, 1284).—3. By the action of benzyl chloride on sodium benzene-sulphinate.—4. By oxidation of di-benzyl sulphide.

**Properties.**—Small needles. Insol. water, sol. alcohol, benzene, and acetic acid. By oxidising agents it is readily oxidised to benzoic and sulphuric acids (Otto, *B.* 13, 1277).

**BENZYL-SULPHONIC ACID** v. **TOLUENE-azo-SULPHONIC ACID.**

**DIBENZYL-SULPHONIC ACID** v. **DIPHENYL-ETHANE SULPHONIC ACID.**

**DI-BENZYL SULPHOXIDE**  $\text{C}_{12}\text{H}_{10}\text{SO}$  i.e.  $(\text{CH}_2\text{Ph})_2\text{SO}$ . [133°]. From di-benzyl sulphide and cold  $\text{HNO}_3$  (S.G. 1.3) (Märcker, *A.* 136, 89; Otto a. Ludwig, *B.* 13, 1284). Laminæ (from water or alcohol).

**BENZYL-SULPHUROUS ACID** v. **TOLUENE-SULPHONIC ACID.**

**BENZYL-TARTRONIC ACID**  $\text{C}_{10}\text{H}_{10}\text{O}_3$  i.e.  $\text{C}_6\text{H}_5\text{CH}_2\text{C}(\text{OH})(\text{CO}_2\text{H})_2$ . [143°]. Formed simultaneously with cinnamic acid by the action of  $\text{KOH}$  on benzyl-chloro-malonic ether. On heating it forms  $\beta$ -phenyl- $\alpha$ -oxy-propionic acid (phenyl-lactic acid [98°]) (Conrad, *B.* 13, 2160; *A.* 209, 215).

**BENZYL-TEREPHTHALIC ACID** v. **BENZYL-PHTHALIC ACID.**

**BENZYL-THIO-CARBAMIDINE**  $\text{C}_8\text{H}_{10}\text{N}_2\text{S}$  i.e.  $\text{NH}_2\text{C}(\text{NH}_2)\text{S}\cdot\text{CH}_2\text{Ph}$ . Cyanamide benzyl-mercaptan. [72°]. From benzyl chloride and thio-urea (Bernthsen a. Klinger, *B.* 12, 575). Slender needles, m. sol. water, decomposed by heat into benzyl mercaptan and di-cyan-diamide.  $\text{B}^+\text{HCl}$ . [168°].— $\text{B}^+\text{H}_2\text{PtCl}_6$ .

**BENZYL-THIO-CARBIMIDE**  $\text{C}_8\text{H}_9\text{CH}_2\text{N}\cdot\text{CS}$ . Benzyl mustard oil. [243°]. Benzylamine is dissolved in  $\text{CS}_2$  and the product boiled with alcohol and  $\text{HgCl}_2$  (Hofmann, *Z.* [2] 4, 690; *B.* 1, 201). Oil, smelling like water-cress.

**BENZYL-THIO-GLYCOLLIC ACID** v. **THIO-GLYCOLLIC ACID.**

**BENZYL-THIO-UREA**  $\text{C}_8\text{H}_{10}\text{N}_2\text{S}$  i.e.  $(\text{CH}_2\text{Ph})\text{NH}\cdot\text{CS}\cdot\text{NH}_2$ . [101°]. From potassium sulphocyanide and benzylamine hydrochloride (Paterno a. Spica, *G.* 5, 388; *B.* 9, 81). Sol. water and alcohol.

**Benzoyl derivative**  $\text{C}_8\text{H}_9\text{NH}\cdot\text{CS}\cdot\text{NH}\cdot\text{Bz}$ . [145°]. From benzoyl sulphocyanide and benzylamine (Miquel, *A. Ch.* [5] 11, 313).

**s-Di-benzyl-thio-urea**  $(\text{Ph}\cdot\text{CH}_2\text{NH})_2\text{CS}$ . [114°]. From alcoholic benzylamine and  $\text{CS}_2$  (Strakosch, *B.* 5, 692). Four-sided plates, insol. water, sol. alcohol and ether. Converted by  $\text{HgO}$  into di-benzyl-urea. Alkali iodides give the following derivatives:

$\text{PhCH}_2\text{NH}\cdot\text{CS}\cdot\text{N}(\text{C}_6\text{H}_5)_2\cdot\text{CH}_2\text{Ph}$  (Reimarus, *B.* 19, 2348).

**u-Di-benzyl-thio-urea**  $(\text{PhCH}_2)_2\text{N}\cdot\text{CS}\cdot\text{NH}_2$ . [157°]. From potassium sulphocyanide and dibenzylamine hydrochloride (P. a. S.). Large needles, m. sol. water.

**BENZYL-THYMOL**  $\text{C}_{11}\text{H}_{12}\text{O}$  i.e.

$\text{C}_6\text{H}_5\text{MePr}(\text{CH}_2\text{Ph})(\text{OH})$ . [255°] at 8 mm. Formed, together with di-benzyl-thymol by heating benzyl chloride with thymol and zinc-dust (Mazzara, *G.* 11, 346). Oil, insol. aqueous alkalis, sol. alcohol and ether.  $\text{FeCl}_3$  gives a red colour on heating.

**Acetyl derivative**  $\text{C}_{11}\text{H}_{11}\text{AcO}$ . [245°] at 8 mm.

**Di-benzyl thymol**  $\text{C}_{22}\text{H}_{24}\text{O}$  i.e.

$\text{C}_6\text{H}_5\text{MePr}(\text{CH}_2\text{Ph})_2\text{OH}$ . [76°]. Prepared as above. Silky laminae, sol. ether and  $\text{HOAc}$ , insol. water and aqueous alkalis.  $\text{FeCl}_3$  gives a red colour on heating.

**Acetyl derivative**  $\text{C}_{22}\text{H}_{22}\text{AcO}$ . [c. 84°].

**Methyl derivative**  $\text{C}_{22}\text{H}_{24}\text{MeO}$ . [90°].

**Benzoyl derivative**  $\text{C}_{22}\text{H}_{22}\text{BzO}$ . [c. 78°].

**BENZYL-TOLUENE** v. **DIPHENYL-TOLYL-METHANE.**

**DI-BENZYL-TOLUENE**  $\text{C}_{21}\text{H}_{22}$  i.e.

$\text{CH}_3\cdot\text{C}_6\text{H}_4(\text{CH}_2\text{Ph})_2$ . [c. 394°]. A product of the action of benzyl chloride on toluene in presence of zinc-dust (Weber a. Zincke, *B.* 7, 1154).

**BENZYL-p-TOLUIDINE**  $\text{PhCH}_2\text{NH}_2\cdot\text{C}_6\text{H}_4\text{Me}$ . (313°). From benzylidene-p-toluidine (Köhler, *A.* 241, 359).

**Di-benzyl-p-toluidine**  $\text{C}_{22}\text{H}_{23}\text{N}$  i.e.

$(\text{Ph}\cdot\text{CH}_2)_2\text{N}\cdot\text{C}_6\text{H}_4\text{Me}$ . [55°]. From benzyl chloride and p-toluidine (Cannizzaro, *A. Suppl.* 4, 80). Slender needles, m. sol. cold alcohol. Weak base.

**BENZYL-TOLYL** v. **TOLYL-BENZYL.**

**BENZYL-TOLYL-METHANE** v. **PHENYL-TOLYL-ETHANE.**

**BENZYL-TOLYL OXIDE** v. **BENZYL ALCOHOL.**

**BENZYL-UREA**  $\text{C}_8\text{H}_{10}\text{N}_2\text{O}$  i.e.

$\text{NH}_2\cdot\text{CO}\cdot\text{NH}\cdot\text{CH}_2\text{Ph}$ . [147°]. Formed, together with di-benzyl-urea, by heating benzyl chloride with potassium cyanate in alcoholic solution (Cannizzaro, *G.* 2, 41). Also from benzyl cyanate and alcoholic  $\text{NH}_3$  (Letts, *C. J.* 25, 448) or from benzylamine chloride and potassium cyanate (Paterno a. Spica, *G.* 5, 388; *B.* 9, 81). Long needles (from alcohol); m. sol. water. At 200° it splits up into  $\text{NH}_3$  and s-di-benzyl-urea.

**s-Di-benzyl-urea**  $(\text{CH}_2\text{Ph}\cdot\text{NH})_2\text{CO}$ . [167°].

**Formation.**—1. From benzyl chloride and  $\text{KNCO}$  or urea.—2. From benzyl-urea by heating.—3. By heating benzyl alcohol with urea nitrate (Campisi a. Amato, *G.* 1, 39; *B.* 4, 412). 4. From s-di-benzyl-thio-urea,  $\text{HgO}$ , and alcohol (Strakosch, *B.* 5, 692).

**Properties.**—Needles, insol. water, v. sol. alcohol. Weak base.

**u-Di-benzyl urea**  $(\text{CH}_2\text{Ph})_2\text{N}\cdot\text{CO}\cdot\text{NH}_2$ . [125°].

From di-benzyl-amine hydrochloride and  $\text{KNCO}$  (Paterno a. Spica, *G.* 5, 388; *B.* 9, 81). Thick prisms; sl. sol. cold water.

**BENZYL-URETHANE** v. **BENZYL-CARBAMIC ACID.**

**BENZYL-m-XYLENE**  $\text{C}_{11}\text{H}_{12}$  i.e.

$\text{C}_6\text{H}_4\cdot\text{CH}_2\cdot\text{C}_6\text{H}_4\text{Me}_2$ . **Phenyl-xylyl-methane** (296° i. v.). From m-xylene, benzyl chloride, and zinc-dust or  $\text{Cu}$  (Zincke, *B.* 5, 799; 9, 1761). Oxidation gives benzoyl-iso-phthalic acid. Appears also to be formed by reducing phenyl xylyl ketone with  $\text{HI}$  (Sölscher, *B.* 15, 1682).

**Benzyl-p-xylene.** (295°). From p-xylene, benzyl chloride and zinc-dust (*Z.*).

**BENZYL XYLYL KETONE**  $\text{C}_{12}\text{H}_{12}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{C}_6\text{H}_4(\text{CH}_3)_2$ . [124°]. **Dimethyl-**

**acrybenzoin** (above 350°). Fluid. Formed by the action of  $\text{Al}_2\text{Cl}_6$  on a mixture of *m*-xylene and phenyl-acetyl-chloride. On oxidation it gives di-methyl-benzoic acid (Söllscher, *B.* 15, 1881).

**BERBERAMINE**  $C_{19}H_{21}O_4N$  [1563]. Occurs in the root of *Berberis vulgaris*, together with berberine, oxy-acanthine, and at least one other alkaloid. Small plates, containing 2aqs. Easily sol. ether. The hydrochloride forms small plates, the nitrate needles.  $-B^+H_2Cl_2 \cdot PtCl_4$ , 5 or 6aqs; yellow crystalline pp., sl. sol. cold water (Hesse, *B.* 19, 1393).

**BERBERIC ACID**  $C_{12}H_{10}O_4$ , aq. An acid formed by fusing berberine with KOH (Hlasiwetz & Gilm, *J.* 1864, 407). Needles; v. sol. alcohol and ether, m. sol. water.  $FeCl_3$  gives a green colour turned red by ammonium tartrate. Reduces hot Fehling's solution and silver solution.

**BERBERINE**  $C_{22}H_{19}NO_4$ , 1 $\frac{1}{2}$  aq. [120 $\frac{1}{2}$ ].  
 s. 22 at 21°. S. (alcohol) 1 at 15°. Occurs in the root of the barberry, *Berberis vulgaris*, together with oxy-neanthine (q. v.), berhamine and another alkaloid (Buchner, A. 24, 228; Hesse, B. 19, 3190). Occurs also in Colombaroot (*Coccolpis palmatus*) (Floittmann, A. 59, 160; Bödeker, A. 66, 381; 69, 40); in *Menispermum fenestratum* (Perrins, C. J. 15, 339); in *Alibocoota* bark from *Calocotyle polycarpa* (Skonhouse, Ph. 14, 455; C. J. 20, 187; Daniel, A. 105, 360); in *Leonice thalicteroides* (Mayer, J. Ph. [3], 46, 496); in *Xanthoxylon clava Herculis* (Chevallier a. Pelletan, Herz. J. 7, 266); Perrins, A. Suppl. 2, 171); in bark of *Groffroya inermis* (Gustel, J. 1856, 180); in *Coptis trifolia* (Gross, J. 1871, 914); and in the root of *Evodia glauca* (Martin, Ph. [3] 13, 337).

**Preparation.**—1. The finely powdered root of *Hydrastis canadensis* is extracted with alcohol; H<sub>2</sub>SO<sub>4</sub> is added to the cooled extract, and the pp. decomposed by NH<sub>3</sub>. The operation is repeated a second time (Lloyd, *Ph.* [3], 10, 125; cf. Merril, *Am. J. Pharm.* 35, 97; Procter, *C. N.* 9, 112). 2. Barbary root is exhausted with boiling water; the extract evaporated, and treated with 92 p.c. alcohol. The berberine is purified by crystallisation from water or alcohol (Buchner).

**Properties.**—Silky yellow needles; tastes bitter; sl. sol. cold water and alcohol. insol. ether. Turned brown by ammonia. On adding iodine in potassium iodide to a solution of berberine hydrochloride the periodide is ppd. It crystallises from alcohol in red needles, but on adding water, green plates separate.

**Reactions.**—1. Zinc and dilute acids form hydro-berberine. 2. Potash fusion produces two acids,  $C_8H_6O_4$  and  $C_8H_4O_4$  (Hlasiwetz & A. Giln, *J.* 1864, 406). — 3. Nitric acid oxidises it to berberonic acid. — 4.  $KMnO_4$  in presence of  $KHO$  forms hemipic acid,  $[162]$  (E. Schmidt & Schilbach, *Ar. Ph.* 33: 25, 164).

Salts:—(Fleitmann, *A.* 59, 160; Henry, *A.* 116, 132; Ferrins, *C. J.* 15, 339; Hlasiwetz, *A. Suppl.* 2, 191). — *B*·HCl: slender yellow needles. — *B*·HCl 4aq. — *B*·HCl 2aq. S.G.  $\frac{194}{1}$  1397 (Clarke, *Am. J.* 2, 175). — *B*·H<sub>2</sub>HgCl<sub>2</sub>. — *B*·H<sub>2</sub>HgCl<sub>2</sub> (Hinterberger, *A.* 82, 314). — *B*·H<sub>2</sub>Cl·HgCy<sub>2</sub> (Kohl & Swoboda, *J.* 1852, 550). — *B*·H<sub>2</sub>PuCl<sub>4</sub>: small needles. S.G.  $\frac{1758}{1}$  (C.). — *B*·H<sub>2</sub>AsCl<sub>4</sub>: maroon-colored needles.

*Ethylo-iodide* B'EtI: prisms.

BERBERONIC ACID v. PYRIDINE-TRI-CARBOXYLIC ACID.

**BERGAMOT, OIL OF.** An aromatic essential oil expressed from the rind of an orange, *Citrus bergamia*. Its S.G. is .87. It contains a stearoptene, a terpene, and a terpene hydrate (?). By rectification a liquid (183°) may be gotten, which absorbs HCl (Soubreiran a. Capitaine, *J. Ph. 26*, 68, 509). The stearoptene (*Bergaptene*) is deposited after long keeping. It is solid, [206°], but volatilises without decomposition. It may be  $(C_{10}H_{16})_x$  (Mulder, *A. 31*, 70; Ohmo, *A. 31*, 316).

**B**ERGENITE  $C_{12}H_{10}O_8$ , aq. [130°]. S.G. 1.5  
[ $\alpha$ ]<sub>D</sub> =  $-51^\circ 36'$ . Obtained from Siberian saxi-  
frage (*Bergenia siberica*) by extracting with hot  
water, ppt. the tannins with lead acetate, and evap-  
orating to crystallisation (Morelli, *C. R.* 93,  
616). Trimetric prisms. Tastes bitter. V. sl.  
sol. gold alcohol and water.

*Acetyl derivative*  $C_{11}H_{13}AcO_2$ : amorphous, v. sol. water, alcohol, and ether.

*Tri-acetyl derivative*  $C_9H_9Ac_3O_6$ .

Penta-acetyl derivative  $C_5H_5Ac_5O_{10}$ .

**BERLIN BLUE** = Prussian Blue v. *Ferrocyanide of iron* under **CYANIDES**.

**BERONIC ACID v. PYRIDINE DI-CARBOXYLIC ACID.**

**BERYLLIUM**, Be. (*Glucinum*). At. w. 9.08. Mol. w. unknown. S.G. 2.90 (after compression) 1.85 (Humpidge, *Pr.* 39, 1). S.H. (100°) -4702; (200°) -540; (400°) -6172; (500°) -6206 (Humpidge, *Pr.* 39, 1). S.H. 2080° -397; (73°) -448; (137°) -519; (237°) -581 (Meyer's calculation, *B.* 13, 1780, from data of Nilson and Petterson who worked with metal containing about 95 p.c. Be; *B.* 13, 1451). S.V.S. 4.92. Crystallises in hexagonal, holohedral, forms; *a*:*c* = 1:1.5901 (Rogger & Flink, *B.* 17, 819).

**Occurrence.**—Only in combination; in *beryl* ( $3\text{BeO} \cdot \text{Al}_2\text{O}_3 \cdot 6\text{SiO}_2$ ) and some other silicates, also in *chrysoberyl*  $\text{Al}_2\text{O}_3 \cdot \text{BeO}$ . Beryllium oxide was recognised as a distinct body in 1797 by Vauquelin, the metal was obtained by Wöhler in 1827, but approximately pure beryllium was not prepared until 1885, in which year Hum-  
pidge obtained specimens containing 99.2 p.c. Be, .1 Fe, and .7 BeO.

**Preparation.**—Wöhler (*P.* 13, 577) obtained an impure metal by the action of K on fused

**BeCl<sub>2</sub>:** Debray (*O. R.* 88, 784) obtained pure specimens by using Na and a special form of apparatus. Nilson a. Pettersson, by decomposing BeCl<sub>2</sub> by Na in closed iron crucibles heated in a wind-furnace (*B.* 11, 381), and sifting the crystals through Pt gauze (*B.* 13, 1455), obtained specimens containing 94.4 p.c. Be (BeO = 4.89, Fe = .70). Humpidge (*Pr.* 38, 188; 39, 1) purified BeO by solution in (NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub> and decomposing the solution by steam; he mixed the BeO thus obtained with pure charcoal and starch paste and heated in Cl in a glazed porcelain tube; the BeCl<sub>2</sub> thus obtained was placed in an iron boat, and this in an iron tube surrounded by another tube of hard glass; another iron boat contained Na; the Na was heated in a stream of H, and the BeCl<sub>2</sub> was then vaporised (in H) over the molten Na. The crystals of Be were washed in dilute NaOH aq. to remove BeO, then in water, and dried.

**Properties.**—Steel-coloured, hard, hexagonal, holohedral (Brögger a. Flink, *B.* 17, 849) crystals. Unchanged in ordinary air; scarcely changed by heating in air. Scarcely acted on by O or S at red heat, but burns in Cl to BeCl<sub>2</sub> (Nilson a. Pettersson, *B.* 11, 381). Burns in O-H flame (Humpidge, *T.* 174, 601). Dissolves slowly in acids, also in aqueous alkalis, with evolution of H. Many of the properties ascribed to Be by Wöhler (*P.* 13, 577), and Debray (*A. Ch.* [3] 41, 5), were the results of experiments with very impure material. Emission-spectrum characterised by the lines 3320.5, 2649.4, 2493.2, and 2477.7, of which 3320.5 is the most prominent (Hartley, *C. J.* 43, 316). The atomic weight of Be has been determined (i) by analyses, and determinations of V.D., of BeCl<sub>2</sub> and BeBr<sub>2</sub>; (ii) by determinations of S.H. of Be; (iii) by analyses of various compounds, especially recently of the pure crystallised sulphate by Nilson a. Pettersson (*B.* 13, 1451) [for older analyses v. Berzelius, *P.* 8, 187; Awdejew, *P.* 56, 101; Klatzo, *J. pr.* 106, 227]; (iv) by the application of the periodic law. There has been much investigation and discussion concerning the value to be given to the atomic weight of Be; some chemists insisted that 13.65 is the true value, and that the oxide is Be<sub>2</sub>O<sub>3</sub>. The determinations of the V.D. of BeCl<sub>2</sub> and BeBr<sub>2</sub>, the careful measurement of the S.H. of almost pure Be, and the consideration of the physical and chemical relations of Be and its compounds to other elements carried out on the lines suggested by the periodic law, have finally established the value 9.08-9.1 for the atomic weight of Be. The S.H. of Be increases rather rapidly as the temperature increases, and approaches a constant value, equal to about .62, between 400° and 500° (Humpidge, *Pr.* 39, 1). The relation between S.H. and temperature is expressed by the empirical formula  $K_1 = 3756 + .00106t - .0000011t^2$  (Humpidge, *Pr.* 38, 188). The product of S.H. into At. w. (.62 × 9.1 = 5.64) is lower than the mean value of this quantity for the solid elements, but is nearly the same as that obtained for B, O, and Si. The atom of Be is divalent in the gaseous molecules BeCl<sub>2</sub> and BeBr<sub>2</sub>; these are the only compounds of Be at present known in the gaseous state. A comparison of the spectrum of Be with those of In and Al on the one

hand, and of Mg, Ca, Ba, Sr, on the other, shows that Be is rather to be classed with the latter than with the former elements; the value 9.1 for the atomic weight of Be is thus confirmed (v. Hartley, *C. N.* 48, 195). Beryllium is a markedly positive, or metallic, element; it does not exhibit allotropy. It is chemically related to Mg, Ca, Sr, and Ba, in much the same way that Li is related to Na, K, Cs, and Rb. BeO resembles MgO, but is distinctly less basic; e.g. it dissolves in KOH aq. and does not combine directly with H<sub>2</sub>O; compare also [BeO·H<sub>2</sub>, H<sub>2</sub>SO<sub>4</sub>·Aq] = 16,096, with [MgO·H<sub>2</sub>, H<sub>2</sub>SO<sub>4</sub>·Aq] = 31,216. Analogies also exist between Be and Al; e.g. the existence of many basic salts; Be, however, does not form an alum; BeCl<sub>2</sub> does not combine with NaCl and KCl as AlCl<sub>3</sub> does. In dilute acid solutions Be is electronegative to Mg but positive to Al; in caustic alkali solutions the electrochemical order is +Al, Mg, Be—(Humpidge, *Tr.* 174, 601). Be forms only one series of compounds, BeCl<sub>2</sub>, BeSO<sub>4</sub>, Be<sub>2</sub>NO<sub>3</sub>, &c.; it exhibits a marked tendency to form basic salts, e.g., BeSO<sub>4</sub>·BeO·3H<sub>2</sub>O, BeCO<sub>3</sub>·3BeO·5H<sub>2</sub>O, &c. Brauner (*B.* 14, 53) sums up the chemical relations of Be in the three statements (1) Li:Be = Be:B. (2) Li:Na = Be:Mg = B:Al. (3) Li:Mg = Be:Al = B:Si. The chemical relations of Be will be more fully discussed in the art. MAGNESIUM METALS; v. also the remarks on Group II. in art. CLASSIFICATION. The following are the principal papers bearing on the At. w. of Be: Reynolds, *P. M.* [5] 3, 38; *ibid.* *Pr.* 35, 218; Humpidge, *Pr.* 35, 358; 38, 188; 39, 1; Hartley, *C. J.* 43, 316; *ibid.* *Pr.* 36, 462; Carnelley, *Pr.* 29, 190; *ibid.* *B.* 17, 1357; Brauner, *B.* 11, 872; 14, 53; Meyer, *B.* 11, 677; 13, 1780; Nilson a. Pettersson, *B.* 11, 381, 906; 13, 1451, 2035; 17, 987.

**Reactions.**—As most of the reactions said to characterise Be have been obtained by experimenting with material far from pure, the following statements must be accepted as provisional only.—1. *Hydrochloric acid*, whether gaseous or aqueous, reacts readily to produce BeCl<sub>2</sub>.—2. *Sulphuric acid* dissolves Be, forming BeSO<sub>4</sub> aq.—3. *Nitric acid* acts very slowly even when hot and concentrated.—4. Be dissolves in warm KOH aq. or NaOH aq.

**Combinations.**—1. Be combines readily with Cl, Br, and I to form BeCl<sub>2</sub>, BeBr<sub>2</sub>, and BeI<sub>2</sub>, respectively.—2. It also combines very readily with Si; and, according to the observations of Wöhler, made, however, with very impure material, with P, Se, and S; later experiments seem to show that Be and S do not combine when heated together (Nilson a. Pettersson, *B.* 11, 381).—3. An alloy of Be and Fe was described by Stromeyer as a white solid, less malleable than iron, obtained by strongly heating BeO with Fe and charcoal.

**Detection.**—1. *Caustic polish or soda pps.* BeOH<sub>2</sub> soluble in excess, but reppd. on diluting and boiling.—2. *Ammonium carbonate pps.* the carbonate easily soluble in excess; this reaction distinguishes salts of Be from salts of Al.—3. Be salts give no colour when heated with Co<sub>2</sub>NO<sub>3</sub>.

**Estimation.**—As oxide, by ppg. by excess of NH<sub>4</sub> aq. washing, drying, and strongly heating. BeO is separated from Al<sub>2</sub>O<sub>3</sub> by the action of

$(\text{NH}_4)_2\text{CO}_3$  (v. Hofmeister, *J. pr.* 76, 1); or by converting the alumina into potash alum (v. Scheffer, *A.* 109, 144).

**Beryllium, Alloys of.** Little or nothing is known; v. **BERYLLIUM, Combinations**, No. 3.

**Beryllium, Bromide of.**  $\text{BeBr}_2$ . Mol. w. 168.6. (abt. 600°) (Carnelley, *B.* 17, 1357); sublimes readily at 450°. V. D. 90 (Humpidge, *P.* 38, 188).

**Preparation.** -1. By heating Be in Br vapour (Wöhler, *P.* 13, 577). -2. By heating BeO mixed with charcoal and made into a paste with starch, in dry Br (Humpidge, *T.* 174, 601). Crystals of hydrated  $\text{BeBr}_2$  are obtained by dissolving freshly ppt.  $\text{BeO.H}_2\text{O}$  in  $\text{HBrAq}$ , and evaporating (Berthelot, *A. Ch.* [2] 44, 394).

**Properties.** Long white needles; very deliquescent. Heated in air, partly sublimes, and is partly decomposed into BeO and Br.

**Beryllium, Chloride of.**  $\text{BeCl}_2$ . Mol. w. 80, at low temp. 160.  $\text{BeCl}_2$  [about 600°] but sublimes considerably lower (Carnelley, *C. J.* 37, 26; v. also *ibid.* *B.* 17, 1357). V. D. (685° to 1500°) 40:96 (mean of 4); V. D. (520°) 60:4 (Nilson a. Pettersson, *B.* 17, 987; *J. pr.* [2] 33, 1).

**Preparation.** -1. By heating Be in  $\text{Cl}_2$ . -2. By heating BeO and C in  $\text{Cl}_2$ , and subliming in  $\text{HCl}$ . -3. By heating Be in perfectly dry  $\text{HCl}$ , and subliming in the same (Nilson a. Pettersson, *B.* 17, 987).

**Properties.** Snow-white crystalline mass; easily fused and volatilised; melts to a colourless refractive liquid; may be sublimed unchanged in pure dry N or  $\text{CO}_2$ ; but is easily decomposed into BeO and Cl if a little air is present (Nilson a. Pettersson, *B.* 17, 987). Is practically a non-conductor of electricity (Nilson a. Pettersson, *B.* 11, 382; Humpidge, *T.* 174, 601).

**Reactions.** -Dissolves in water with production of much heat; on evaporation, an orange chloride  $\text{Be}_2\text{OCl}_2.\text{H}_2\text{O}$  ( $=\text{BeCl}_2.\text{BeO.H}_2\text{O}$ ) is obtained; if the solution is placed over  $\text{H}_2\text{SO}_4$  under a bell-jar, crystals of  $\text{BeCl}_2.\text{H}_2\text{O}$  separate out (Awdejew, *P.* 56, 101; Atterberg, *Bl.* [2] 24, 358).

**Combinations.** -1. With chlorides of various heavy metals, to form double compounds; especially  $\text{BeCl}_2.3\text{HgCl}_2.6\text{H}_2\text{O}$ , and  $\text{BeCl}_2.\text{SnCl}_4.8\text{H}_2\text{O}$  (Atterberg, *B.* 7, 473);  $\text{BeCl}_2.\text{PtCl}_2.9\text{H}_2\text{O}$  (Thomson, *B.* 3, 827; 7, 75). The salt  $\text{BeCl}_2.\text{PtCl}_2.9\text{H}_2\text{O}$  is analogous in composition to the Ca double salt  $\text{CaCl}_2.\text{PtCl}_2.9\text{H}_2\text{O}$ ; dried from 120° to 200° the Be salt retains  $\text{H}_2\text{O}$ , and corresponds with double Ba-Pt salt,  $\text{BaCl}_2.\text{PtCl}_2.4\text{H}_2\text{O}$ . 2. With ether to form  $\text{BeCl}_2.2(\text{C}_2\text{H}_5)_2\text{O}$  (Atterberg, *Bl.* [2] 24, 358).

**Beryllium, Fluoride of.** Hydrated BeO dissolves easily in  $\text{HFaq}$ ; on evaporation, a transparent, gum-like mass is obtained which becomes opaque at 100°, but remains soluble in water; this is probably  $\text{BeF}_2$  (Berzelius). The double compounds  $\text{BeF}_2.2\text{KF}$ , and  $\text{BeF}_2.\text{KF}$ , are described by Marignac (*A. Ch.* [4] 30, 45), the former obtained by adding much  $\text{KFAq}$ , the latter by adding little  $\text{KFAq}$ , to a solution of  $\text{BeO.H}_2\text{O}$  in  $\text{HFaq}$ , and evaporating. The compounds  $2\text{NaF}.\text{BeF}_2$ ,  $\text{NaF}.\text{BeF}_2$ , and  $2\text{NH}_4\text{F}.\text{BeF}_2$ , are also described by Berzelius.

**Beryllium, Hydrated oxide of, v. **BERYLLIUM, HYDROXIDES OF.****

**Beryllium, Hydroxides of.** A compound of Be, H, and O, agreeing in composition with the formula  $\text{BeO.H}_2\text{O}$  ( $=\text{BeO.H}_2\text{O}$ ) is obtained as a white powder by ppg. a hot solution of a Be salt by  $\text{NH}_4\text{Aq}$ , or  $\text{KOH Aq}$ , boiling, collecting, washing, and drying at 100° (Atterberg, *Bl.* [2] 24, 358; Weeren, *P.* 92, 91); on heating more highly, BeO remains. Van Bemmelen (*J. pr.* [2] 26, 227) says that the pp. by  $\text{KOH Aq}$  has the composition  $\text{BeO.H}_2\text{O}$  only when heated to 150°-180°; he describes a gelatinous hydrate,  $\text{BeO.H}_2\text{O}$ , obtained by the action of  $\text{NH}_4\text{Aq}$  on  $\text{BeSO}_4\text{Aq}$ , washing with cold water and drying in dry air at 15°-20°; the composition of this hydrate is constant up to 200°. The compound  $\text{BeO.H}_2\text{O}$  is not re-formed by the action of water on BeO (for more details of this action v. Van Bemmelen, *l.c.*); it seems better to regard it as a hydrated oxide,  $\text{BeO.H}_2\text{O}$ , than as a hydroxide  $\text{Be(OH)}_2$ . Other hydrates of BeO are said to be obtained by drying the pp. by  $\text{NH}_4\text{Aq}$  over  $\text{H}_2\text{SO}_4$ , or merely in air, but the composition of these bodies is variable (v. Schaffgotsch, *P.* 50, 183; Atterberg, *B.* 7, 473; Van Bemmelen, *J. pr.* [2] 26, 227). The gelatinous  $\text{BeO.H}_2\text{O}$  is easily soluble in acids, also in  $\text{NaOH Aq}$  and  $\text{KOH Aq}$ , and in  $(\text{NH}_4)_2\text{CO}_3\text{Aq}$ . By boiling the solution in  $\text{KOH Aq}$  a ppt. of  $3\text{BeO}.\text{Al}_2\text{O}_3$  (Atterberg, *B.* 7, 473) is obtained (but v. Van Bemmelen, *J. pr.* [2] 26, 227).  $\text{BeO.H}_2\text{O}$  acts as a basic hydroxide towards acids; Thomsen gives the following values for its heats of neutralisation, solid  $\text{BeO.H}_2\text{O}$ , being used in each case (*Th.* 1, 363):  $[\text{BeO.H}_2\text{O}.\text{H}^+\text{SO}_4\text{Aq}] = 16,096$ ;  $[\text{BeO.H}_2\text{O}.\text{H}^+\text{ClAq}] = 13,644$ . These values are much less than those for the alkaline earth hydroxides (about 31,000 for  $\text{H}_2\text{SO}_4\text{Aq}$ ).

**Beryllium, Iodide of.**  $\text{BeI}_2$ . Mol. w. unknown, as V.D. has not been determined. Described as colourless needles obtained by heating together Be and I (Wöhler, *P.* 13, 577; Debray, *A. Ch.* [3] 44, 5). Easily decomposed by action of hot air into BeO and I (Debray, *l.c.*).

**Beryllium, Oxide of.** BeO. Mol. w. unknown. S.G. 3.016. S.H. (0° to 100°) 2471 (Nilson a. Pettersson, *B.* 13, 1454). S.V.S. 8.3.

**Preparation.** -Beryl is fused with  $\text{Na}_2\text{CO}_3$ , in graphite crucibles in a wind-furnace; the fused mass is heated for some time with excess of  $\text{H}_2\text{SO}_4\text{Aq}$ , water is added and  $\text{SiO}_2$  removed by filtration, the liquid is evaporated until a crust begins to form and is then allowed to stand for 24 hours or more; potash alum and  $\text{K}_2\text{SO}_4$  separate out; the mother liquor is again evaporated and a second crop of alum crystals is obtained and removed; the mother liquor is now poured into a warm conc. aqueous solution of ammonium carbonate, the pp. (of  $\text{Al}_2\text{O}_3$ , &c.) is filtered in contact with the liquid for four or five days and then filtered, the insoluble portion is again heated with  $(\text{NH}_4)_2\text{CO}_3\text{Aq}$  and the liquid is filtered off. The solution in  $(\text{NH}_4)_2\text{CO}_3\text{Aq}$  contains BeO, free, or almost free, from  $\text{Al}_2\text{O}_3$ ,  $\text{CaO}$ ,  $\text{Fe}_2\text{O}_3$ , &c.; the BeO may be obtained by boiling the solution (Nilson a. Pettersson, *B.* 11, 383), or by acidulating, boiling off  $\text{CO}_2$ , and ppg. by  $\text{NH}_4\text{Aq}$  (Hofmeister, *J. pr.* 76, 3); in either case, the ppt.  $\text{BeO}.\text{H}_2\text{O}$  should be again treated with  $(\text{NH}_4)_2\text{CO}_3\text{Aq}$  and then reppd. There are various other ways of

## BETH-A-BARRA COLOUR.

preparing  $\text{BeO} \cdot x\text{H}_2\text{O}$  from beryl (v. especially Joy, *J. pr.* 92, 232; Scheffer, *A.* 109, 146; Berzelius, *P.* 8, 187; Debray, *A. Ch.* [8] 44, 15).

**Properties.**—A white, loose, infusible powder; insoluble in, and unacted on by, water; soluble in acids and in molten KOH. According to Ebelmen (*A.* 80, 213)  $\text{BeO}$  is obtained in hexagonal crystals ( $a:c=1.1:587$ ) by cooling a solution of the oxide in molten boric acid; Debray obtained similar crystals of  $\text{BeO}$  by strongly heating ammonium-beryllium carbonate (*A. Ch.* [3] 44, 15). H. Rose described crystals of  $\text{BeO}$  obtained by heating the ordinary oxide in a porcelain oven (*Ph. C.* 1848, 486); S.G. of these crystals = 3.02.

**Reactions and Combinations.**—1. With most acids to form salts, e.g.  $\text{BeSO}_4$ ,  $\text{Be}_2\text{NO}_3$ , &c.; the oxide becomes less easily soluble in acids by heating. —2. Decomposes molten potassium carbonate with evolution of  $\text{CO}_2$ ; on addition of water  $\text{BeO}$  remains dissolved in the KOH aq. —3. Does not combine directly with water, but various hydrates, of which  $\text{BeO} \cdot \text{H}_2\text{O}$  is the most important, are obtained by the action of  $\text{NH}_4\text{Aq}$  on solutions of Be salts (v. BERYLLIUM, HYDROXIDES or).

**Beryllium, Oxychloride of.**  
 $\text{Be}_2\text{OCl}_2 = \text{BeCl}_2 \cdot \text{BeO}$ . Said to be formed by evaporating an aqueous solution of  $\text{BeCl}_2$ .

**Beryllium, Phosphide of.** Described by Wöhler as a greyish powder obtained by heating Be in vapour of P; existence very doubtful as Wöhler's Be was very impure.

**Beryllium, Salts of.** Salts obtained by replacing H of acids by Be: they are generally obtained by the action of aqueous acids on  $\text{BeO} \cdot \text{H}_2\text{O}$ . Most of the commoner salts—sulphate, nitrate, oxalate, chloride—are soluble in water and have a sweetish taste; the carbonate and phosphate are insoluble in water. When heated, the salts of Be are completely decomposed, except the acid be non-volatile. The chief salts of Be are the following (they are described under the headings CARBONATES, NITRATES, &c.) carbonates, chromates, molybdates, nitrates, perchlorate, periodates, phosphates, selenate, selenites, silicates, sulphates. The following salts probably exist, but few if any definite facts concerning them are known:—bromate, chlorate, hypophosphite, iodate, phosphite, tungstate, vanadates.

**Beryllium, Selenide of.** Existence very doubtful.

**Beryllium, Silicide of.** Be readily combines with Si; when Be is prepared in porcelain vessels a portion of the  $\text{SiO}_2$  is reduced and as much as 20 p.c. Si may combine with the Be to form a hard, brittle mass. It is doubtful whether any definite compound of Be and Si has been obtained.

**Beryllium, Sulphide of.** Described by Wöhler (*P.* 13, 577) as a greyish fused mass, which evolves  $\text{H}_2\text{S}$  by action of acids; obtained by heating Be in S vapour. But existence is extremely doubtful; according to Fremy (*A. Ch.* [3] 38, 326) no sulphide of Be is produced by heating  $\text{BeO}$  in S, or  $\text{CS}_2$ , vapour. According to Nilson a. Pettersson (*B.* 11, 384), Be and S do not combine when heated together.

M. M. P. M.

## BERYLLIUM, ORGANIC DERIVATIVES OF.

**Beryllium ethide  $\text{BeEt}_2$ .** (185°-188°). From  $\text{HgEt}_2$  and Be at 130°. Takes fire in air (Gahours, *J.* 1873, 520).

**Beryllium propide  $\text{BePr}_2$ .** Does not take fire in air.

**BETA.**—Compounds beginning with *beta-* or *bet-* are described as  $\beta$  compounds under the word to which this prefix has been added.

**BETAINE**  $\text{C}_3\text{H}_{11}\text{NO}_2$ , i.e.  $\text{Me}_3\text{N} \cdot \text{CH}_2 \cdot \text{CO}_2\text{H}$ .

**Internal anhydride of the methyl-hydroxide of di-methyl-amido-acetic acid.** S. 16 at 25°. In the hydrated condition  $\text{C}_3\text{H}_9\text{NO}_4$ , it may be represented by the formula  $\text{Me}_2\text{N}(\text{OH}) \cdot \text{CH}_2 \cdot \text{CO}_2\text{H}$ .

**Occurrence.**—1. In the juice of beet-root (*Beta vulgaris*), and in beet-root molasses (Scheibler, *Z.* 6, 505; *B.* 3, 155; Liebreich, *Z.* 6, 506; *B.* 3, 161). The unripe root contains 25 p.c.; the ripe root only 1 p.c. The betaine is not present in the root as such, but is liberated by treatment with HCl or baryta. —2. In man-gold wurzel (Scheibler, *Z.* [2] 5, 533). —3. In cotton seed (Lithausen, *J. pr.* [2] 30, 32). —4. In the leaves and branches of *Lycium barbarum* (Marmé a. Husemann, *A. Suppl.* 2, 383; 3, 245; *Ar. Ph.* [3] 6, 216). —5. In putrefying flesh (Gautier, *Bl.* [2] 48, 13).

**Formation.**—1. From tri-methyl-amine and chloro-acetic acid (Liebreich, *B.* 2, 13). —2. By oxidation of neurine  $\text{Me}_3\text{N}(\text{OH}) \cdot \text{CH}_2 \cdot \text{CH}_2\text{OH}$ . 3. Glycocoll (1 mol.) is dissolved in KOH aq and mixed with MeI (3 mols.) and MeOH; the liquid being kept alkaline (Griess, *B.* 8, 1400). 4. Silver glycocoll and MeI gives the iodide,  $\text{Me}_3\text{N} \cdot \text{CH}_2 \cdot \text{CO}_2\text{H}$ .

**Preparation.**—1. Diluted molasses are boiled for twelve hours with baryta; excess of baryta is removed from the filtrate by  $\text{CO}_2$ ; the liquid is evaporated to a treacle and exhausted with alcohol; the alcoholic solution is treated with alcoholic  $\text{ZnCl}_2$ ; the pp. is recrystallised from water, and decomposed by baryta; the barium is exactly removed from the filtrate by  $\text{H}_2\text{SO}_4$ , and betaine hydrochloride crystallises on evaporation (Liebreich, *B.* 3, 161; cf. Scheibler, *B.* 2, 292; Frühling a. Schulz, *B.* 10, 1070).

**Properties.**—Large crystals (containing aq) (from alcohol). Ppd. as plates by adding ether to an alcoholic solution. Deliquescent. Over  $\text{H}_2\text{SO}_4$ , the crystals become  $\text{C}_3\text{H}_9\text{NO}_2$ . Sweet taste; neutral to litmus; inactive. Decomposed by heat, giving off odours of  $\text{NMe}_3$  and of burnt sugar. Not affected by  $\text{CrO}_3$  or  $\text{HI}$ . Fusion with potash gives off  $\text{NMe}_3$ . Iodine in KI pps. brown needles of a periodide.

**Salts.**— $\text{B}^+\text{HCl}$  or  $\text{Me}_3\text{N} \cdot \text{CH}_2 \cdot \text{CO}_2\text{H}$ : monoclinic tables, v. sol. water.  $\text{B}^+\text{HAuCl}_4$ : plates or thin needles.  $\text{B}^+\text{H}_2\text{PtCl}_4$  2aq (H.).  $\text{B}^+\text{H}_2\text{PtCl}_4$  4aq (L.).  $\text{B}^+\text{HCl}_3$ :  $\text{H}_2\text{O}$ .  $\text{B}^+\text{ZnCl}_2$ .  $\text{B}^+\text{KI}$  2aq [139°] (Körner a. Menozzi, *G.* 13, 351).  $\text{B}^+\text{KI}$  [226°].  $\text{B}^+\text{H}_2\text{I}_4(\text{Bi})_2$  (Kraut, *A.* 210, 318).  $\text{B}^+\text{H}_2\text{SO}_4$ .

**Methyl ether.**—Iodide  $\text{INMe}_3 \cdot \text{CH}_2 \cdot \text{CO}_2\text{Me}$ . From silver glycocoll and MeI (Kraut, *A.* 182, 180).

**BETH-A-BARRA COLOUR**  $\text{C}_{20}\text{H}_{18}\text{O}_2$ . (135°). A dye extracted from a West African wood (Sadler a. Rowland, *Am.* 3, 22). When dried at 100° it contains 3aq in the molecule.

**BETORCIN**  $C_8H_8O_2$  (4.  $C_8H_8Me_2(OH)_2$  [1:4:3:5]. [168°]. (c. 279°).  $\beta$ -Orcin. Di-*o*-*p*-xylene. Di-methyl-resorcin.

**Formation.**—1. By boiling ( $\beta$ )-picroerythrin with baryta (Stenhouse, A. 68, 101; Lamparter, A. 184, 248; Menschutkin, *Bl.* 2, 428).—2. From amido-xylene,  $C_8H_8Me_2(NH_2)(OH)$  [1:4:3:5] by the diazo-reaction (Kostanecki, B. 19, 2321).

**Preparation.**—The lichen *Usnea barbata* is thoroughly extracted with cold water (10 pts.) and CaO (1 pt.), the extract is mixed with HCl. A pp. of usnic and barbatic acids is formed. This mixture (1 pt.) is boiled with water (40 pts.) and CaO (1 pt.) for four hours. An insoluble basic calcic usnate is formed while the barbatic acid splits up into  $CO_2$  and betorcin. Air must be excluded, for betorcin oxidises very readily. The filtrate is at once neutralised with HCl, acidified strongly with acetic acid, evaporated (to 5 pts.) filtered from some tarry matter, and evaporated further to crystallisation. Recrystallised first from benzene, then from water. Yield  $\frac{7}{10}$  per cent. (Stenhouse & Groves, C. J. 87, 896).

**Properties.**—Less soluble in water than orcin. Gives a more crimson colour with hypochlorites than orcin does. FeCl<sub>3</sub> gives a green colour. Ammoniacal solutions turn red in air. Boiled with NaOH and chloroform it forms a red, non-fluorescent solution.

**BETULIC ACID**  $C_{22}H_{34}O_8$ . [195°]. From betulon and CrO<sub>3</sub> in HOAc (Hausmann, A. 182, 378). White powder, v. sl. sol. water, v. sol. alcohol.—Ph. ( $C_{22}H_{34}O_8$ ).

**BETULIN**  $C_{22}H_{36}O_7$ . [251°]; [258° cor.] (Hausmann, A. 182, 369). S. (alcohol) 7 at 15°; 4.2 at 78°. Occurs in the bark of the birch (Lowitz, *Crell. Chem. Ann.* 1788, i. 302; Hünefeld, *J. pr.* 7, 53; Hess, *J. pr.* 16, 161; Stähelin & Hofstetter, A. 51, 79; Paterno & Spica, G. 7, 508).

**Preparation.**—The bark is extracted with 96 p.c. alcohol, the alcohol evaporated and the residue after washing with water and with soda-solution is crystallised from benzene or naphtha, the crystals are finally decolourised with animal charcoal and recrystallised from alcohol (Franchimont, B. 12, 7).

Needles; may be sublimed. Insol. water, v. sl. sol. CS<sub>2</sub>, sl. sol. alcohol and ether. At 130° it gives an Anhydride  $C_{22}H_{34}O_6$ . On distillation alone with powdered zinc, P<sub>2</sub>O<sub>5</sub> or P<sub>2</sub>S<sub>5</sub>, hydrocarbons are produced of doubtful constitution.

**Acetyl derivative**  $C_{22}H_{36}O_9$  (OAc)<sub>2</sub> [216°].

**BETULIN-AMARIC ACID**  $C_{22}H_{34}O_{10}$ . From betulin and fuming HNO<sub>3</sub> (Hausmann, A. 182, 374). Crystals, v. sl. sol. water, v. c. sol. alcohol and ether. At 110° it gives the anhydride  $C_{22}H_{34}O_8$  [181°].

**Salts.**— $K_2C_{22}H_{34}O_{10}$ .— $CaBaC_{22}H_{34}O_{10}$ .— $Ca_2C_{22}H_{34}O_{10}$ .— $Pb_2C_{22}H_{34}O_{10}$ .— $Cu_2C_{22}H_{34}O_{10}$ .

**Ethyl ether EtC<sub>22</sub>H<sub>34</sub>O<sub>10</sub>**. [117°].

**BETULORETIC ACID**  $C_{22}H_{34}O_9$ . [94°]. A white resin found on young birch-shoots and leaves (Kosmann, *J. Ph.* [3] 26, 197). Insol. water, v. sol. alcohol and ether. Oxidised by HNO<sub>3</sub> to picric acid.—Ag $C_{22}H_{34}O_9$ : flocculent pp.

**BEZOAR.**—A concretion found in the stomach or intestines of a variety of goat, *Capra aegragus*,

or of the gazelle, *Antelope Dorcas*. They contain ellagic and lithopellagic acids.

**DICHROMATES**, same as DICHROMATES, q. v. under CHROMIUM, ACIDS OF.

**BICUHYBA FAT.**—The fat of *Myristica bicuhyba* consists chiefly of the glycerides of myristic and oleic acids; it also contains small quantities of resins and free fatty acid (myristic acid), and a very small amount of an ethereal oil (Noerdlinger, B. 18, 2617).

**BIEBRICH SCARLET** v. p. 369.

**BILE.**—A liquid secreted by the liver. It is viscid, of green or brown colour, and has a bitter taste. S.G. about 1.02. Faintly alkaline. Possesses an emulsifying power like soap. Its composition varies. Ox-bile contains sodium glycocholate and taurocholate, cholesterin, urea, fats, salts of acetic and propionic acids, glyceryl triacetate, glyceryl tri-propionate, pigments, mucus, KCl, phosphates of Na, Ca, and Mg, and traces of iron, manganese, and silica. Human bile is of a similar composition.

Latschinoff (B. 18, 3839) has shown that saponified ox-gall contains, in addition to cholic acid (which is derived from the glyco- and tauro-cholic acids), a new acid to which he gives the name *choleic acid*. The latter acid, according to this investigator, occurs in two forms—*anhydrous*  $C_{22}H_{34}O_8$ , and *hydrated*  $C_{22}H_{36}O_9$ . Mylius (B. 19, 369) has found that cholic acid by putrefactive fermentation is reduced to a body (the 'desoxycholic acid' of M.) which L. considers as identical with his so-called 'hydrated choleic acid'. As however L. (B. 20, 1043) was unable to convert his 'anhydrous choleic acid' into the 'hydrated choleic acid' by any other method than by boiling with acetic acid and M. (B. 20, 1968) was unable to effect the conversion even in this way, there appears to be little doubt that these so-called 'anhydrous' and 'hydrated choleic acids' are quite distinct acids (the conversion by AcOH is probably erroneous), the latter being identical with the 'desoxycholic acid' of M. Hence the 'anhydrous' acid will be described as *choleic acid*, the 'hydrated' as *desoxycholic acid*. Both these acids according to L. give *dehydrocholeic acid* on gentle oxidation, and *cholanolic acid* on more vigorous oxidation.

To *cholic acid* L. assigns the formula  $C_{22}H_{34}O_8$ , but M. (B. 19, 369, 2000; 20, 1968) has shown by a long series of careful analyses that, almost beyond a doubt, it is represented by the formula  $C_{21}H_{30}O_8$ , originally proposed for it by Strecker. On oxidation it first gives *dehydrocholeic acid*  $C_{21}H_{28}O_8$ , and then *bilanic acid*  $C_{21}H_{26}O_8$  (but no *cholanolic acid*, which when obtained from cholic acid by earlier investigators, was due to the presence of *choleic acid*).

Pig's bile contains sodium hyoglycocholate and hyotaurocholate instead of glycocholate and taurocholate; it also contains glycerophosphoric acid and neurine derived from the decomposition of lecithin. In other respects it resembles ox-bile. The various constituents of bile are separately described.

**Pettenkofer's test.** Bile, or an aqueous solution of a salt of bile, is mixed with two-thirds of its volume of H<sub>2</sub>SO<sub>4</sub> and a drop of a 10 p.c. solution of sugar is added. On warming to 75° a crimson colour is produced. The reaction is

given by glycocholic, taurocholic, hyoglycocholic, hyotaurocholic, and by cholic acid (Pottenkofer, *A.* 53, 92; cf. Neukomm, *A.* 116, 80; Strassburg, *Pflüger's Arch.*, 4, 461). The test may be modified by using phosphoric acid. The substance to be tested, together with very little cane sugar, is dissolved in 3 drops of a mixture of syrupy phosphoric acid (5 vols.) and water (1 vol.) and the tube is then dipped into boiling water. A crimson colour soon appears (Kolbe, *J. pr.* [2] 27, 424). A red colour is produced by many other substances than those mentioned, hence it is necessary to confirm it by observing the absorption spectrum which contains three bands: one extending from midway between c and d to d, the second midway between d and e, and the third between b and r (Heynsius & Campbell, *Pflüger's Arch.*, 4, 497; cf. Schenk, *Fr.* 12, 119).

#### BILE COLOURING MATTERS v. PIGMENTS, ANIMAL.

##### BILIANIC ACID

$C_{27}H_{48}O_8$ , probably  $C_{27}H_{48}(CO)_2(CO_2H)_2$ . Formed by further oxidation of dehydrocholic acid  $C_{26}H_{46}(CO)(CHO)CO_2H$ .

*Preparation.*—Cholic acid (20 pts.) in fine powder is added to a mixture of  $K_2Cr_2O_7$  (40 pts.) and  $H_2SO_4$  (60 pts.) in water (160 pts.), finally warming on the water-bath till the reaction is complete. It is isolated by conversion into the acid potassium salt, which is sparingly soluble in alcohol, and then into the di-ethyl-ether (Mylius, *B.* 20, 1981; cf. Clève, *Bl.* [2] 35, 373; Latschinoff, *B.* 19, 480; *Bl.* [2] 46, 818).

*Properties.*—Flat needles (containing  $\frac{1}{2}$  aq.). Tri-basic ketonic acid.

*Salts.*— $A''Ba_2Ga_2$  or  $8aq$ : tables or prisms.  $A''H_2Ba_2aq$ : hexagonal tables, sl. sol. water and alcohol.  $A''_3A''$ .

*Di-ethyl ether  $A''H_2Et_2$ :* [193°]; long flat needles; sol. alcohol, less sol. ether.  $A''Et_2Ba_2$ — $A''Et_2Et_2Pb$ .

*Tri-ethyl ether  $A''Et_3$ :* [127°]; satiny tablets, or thick pillars.

*Di-oxim  $C_{27}H_{48}(C_2NOH)_2(CO_2H)_2$ .* Formed by warming a slightly alkaline solution of bilianic acid with hydroxylamine. Glistening tables. Sol. dilute alcohol, nearly insol. water and absolute alcohol. Dissolves in alkalis, forming acid or neutral salts.

*Di-phenylhydrazide  $C_{27}H_{48}(C_6H_5NH)_2(CO_2H)_2$ :* colourless needles. Nearly insol. acetic acid and hot alcohol, insol. water. Dissolves in alkalis.

*Iso-Bilianic Acid  $C_{27}H_{48}O_8$  (?).* [234°–237°]. Flat needles. Formed in small quantity, together with bilianic acid, by oxidation of cholic acid with  $K_2Cr_2O_7$  and  $H_2SO_4$ .

*Salts.*— $A''H_2K$ : silky rhombic plates, sl. sol. water and alcohol.  $A''_3Ag$ : amorphous pp.  $A''Ba_2Ga_2$ : amorphous, sl. sol. water, insol. alcohol.

*Methyl ether  $A''Me_2$ :* [98°]; needles (Latschinoff, *B.* 19, 1530).

**BILIC ACID  $C_{27}H_{48}O_8$ .** [about 190°]. Prepared by careful oxidation of cholic acid with chromic acid mixture (Egger, *B.* 12, 1058). White needles. Sol. hot water and alcohol, sl. sol. ether. Dibasic acid. It gives Pottenkofer's reaction with sugar and  $H_2SO_4$ . By oxidation it is converted into cholesteric acid ( $C_{27}H_{48}O_8$ ).

**BINARY THEORY OF SALTS.** The same salt was given in ancient times to the solid residue obtained by boiling sea-water; it was then extended to include all solid substances easily soluble in water and obtainable by evaporating watery liquids. At a later time the possession of a taste more or less resembling that of sea-salt was regarded as a characteristic property of all salts. When the composition of the bodies called salts began to be studied, a three-fold division was made into acid salts, alkaline salts, and neutral salts (r. ACID, ALKALI, SALT). Lavoisier's discovery of the nature of oxygen led to the definition of acids as highly oxygenated compounds; and Davy's decomposition of soda, potash, lime, and baryta, showed that these alkaline salts were also compounds of oxygen. But as neutral salts were formed by the mutual action of an acid and an alkali, it followed that they too were oxygenated compounds. A neutral salt, or we may say simply a salt, for the qualifying word neutral had been dropped by this time, was then regarded as constituted of two parts, an acid or electro-negative part, and a basic or electro-positive part. From this time dualistic views prevailed; every compound, said Berzelius, must be constituted of two parts, which may themselves be simple or complex, and of these parts one is positively and the other negatively electrified. Such a salt as sulphate of soda, for instance, was regarded as constructed of positive soda and negative sulphuric acid, rather than as formed by the mutual interaction of the elements sodium, oxygen, and sulphur. When, chiefly as a result of the work of Davy and Dulong, acids had come to be regarded as composed of the positive element hydrogen united with a negative element or group of elements, and salts were said to be formed by putting metals in the place of the hydrogen of acids, the conception of a salt as a binary structure still remained. One part of every salt was a positive element, a metal; the other part was a negative radicle, either a non-metal or a group of non-metallic elements.

In some such way as this arose the binary theory of salts, a theory which is based on the notion of every salt being a definite structure, and which conceives it possible to place all salts in one class, regard being had for classificatory purposes rather to the composition than to the properties of salts (v. CLASSIFICATION AND SALTS).

M. M. P. M.

**BIRCH BARK.** Contains betulin (q. v.) and a kind of tannin which is turned green by  $Fe_2Cl_3$  (Stahelin & Hofstetter, *A.* 54, 79).

**BISMUTH.** *B.* At. w. 208. Mol. w. probably 208 (v. Biltz & Meyer, *Z. P. C.* 4, 249). [268°–3] (Rudberg, *P.* 71, 462; Riemsdyk, *C. N.* 20, 82). (1090°–1150°) (Carnegie & Williams, *C. J.* 35, 255). S.G. 9.759 (Schroder, *P.* 106, 226). S.G. liquid 10.055 (Roberts & Wrightson, *A. Ch.* [5] 30, 274). S.G. is lowered by great pressure. S.H. (20°–48°) 0.305 (Kopp, *T.* 155, 71); (9°–102°) 0.2979 (Bède, *Mém. B.* 1855–56, 28); (liquid 280°–380°) 0.363 (Person, *A. Ch.* [3] 24, 129). C.F. (12°–41°) 0.01333 (Kopp, *A.* 81, 1); (0°–100°) 0.01316 (Matthiessen, *Fr.* 15, 220; v. also Fizeau, *P.* 135, 372; 138, 267). Ht. of fusion at 266°–8–12.640 (Person, *A. Ch.* [3] 24, 129). T. C. (Ag = 100) 1.8 (Wiedemann

a. Franz, P. 89, 497). E. C. at  $0^\circ$  (Hg at  $0^\circ = 1$ ) 8676 (Lorenz, W. 13, 422, 582). Cryst. form, hexagonal,  $a:c = 1:1.3035$ ; isomorphous with Te, As, Sb. S.V.S. abt. 21.3. H.C. [ $\text{Bi}^+$ , O] abt. 95,500 (Woods, P. M. [4] 4, 370). Emission-spectrum characterised by very many lines; in arc-spectrum the predominant lines are 4722.1, 4119, 3595.3, 3510.4, 3396.2, 2593, 2524, 2400.8, 2277 (Livinge and Dewar, T. 174, 187, v. also, regarding spectrum of Bi, Hartley a. Adeney, T. 1881, 63).

**Occurrence.** Uncombined with other elements, in Saxony and other parts of Germany, in Norway, Spain, California, and in Cornwall and Cumberland, &c. Also as  $\text{Bi}_2\text{O}_3$  (*Bismuth ochre*),  $\text{Bi}_2\text{S}_3$  (*Bismuth glance*),  $\text{Bi}_2\text{Te}_3$ ,  $\text{Bi}_2\text{Cu}_2\text{S}_3$ ,  $\text{Bi}_2\text{Pb}_2\text{S}_3$ , &c., &c. Bismuth has been known for many centuries; Basil Valentine (15th century) seems to have been the first to recognise it as a definite metallic body. Bergmann gave the earliest fairly accurate account of its reactions.

**Formation.**—Native bismuth is melted in iron tubes, and the metal is run off from gangue &c. into pots. By remelting with  $\frac{1}{10}$  of its weight of  $\text{KNO}_3$  at as low a temperature as possible, until the nitre forms a solid slag on the surface, approximately pure Bi is obtained.

**Preparation.** Approximately pure metal is dissolved in the minimum quantity of  $\text{HNO}_3\text{aq}$ ; much water is added, the pp. of basic nitrate is washed, boiled twice with pure  $\text{KOH aq}$ , or  $\text{NaOH aq}$  (Herapath, D. P. J. 169, 40), dissolved in as little  $\text{HNO}_3\text{aq}$  as possible, and water is again added. The pp. is washed, dried, mixed with black flux (obtained by heating cream of tartar in a closed vessel) and heated at about  $270^\circ\text{--}280^\circ$  in a closed crucible. The reduced metal is washed in dilute  $\text{HCl aq}$ , and in water, and dried. Traces of As, Sb, or Fe, which yet remain in the metal are removed by partially oxidising and melting under the small quantity of  $\text{Bi}_2\text{O}_3$  formed: this may be effected (1) by adding a little pure  $\text{KNO}_3$ , melting in an open porcelain crucible, keeping molten for some time, allowing to cool until a small quantity of the metal solidifies, and pouring off the still molten metal from the more solid oxides on the surface; (2) by melting under  $\text{Na}_2\text{CO}_3$  containing 2.5 p.c.  $\text{KClO}_3$  and proceeding as in (1) (Türsch, J. pr. [2] 14, 309); (3) by strongly heating with 1 part cream of tartar, then running the molten metal (which contains K) into a crucible containing charcoal, heating for a little, running into an open porcelain vessel, strongly heating in air for some time, and finally pouring off the molten metal from the slag on the surface (Mehu, P. P. J. 211, 187). Löwe (Fr. 22, 498) recommends ppn. of  $\text{Bi}_2\text{NO}_3$  in  $\text{HNO}_3\text{aq}$  by  $\text{KOH}$  solution of pp. in excess of  $\text{KOH}$  in presence of glycerine, addition of grape sugar, filtration from Ag and Cu, and boiling: pure Bi is ppd. Bi is obtained in well-formed crystals by melting the commercial metal with a little  $\text{KNO}_3$  in a crucible until a small quantity taken out appears yellow on the surface (indicative that foreign metals are oxidised), removing the scum of oxides from the surface, covering the molten mass with pieces of charcoal (to prevent oxidation), allowing to cool until a firm crust has formed, piercing two

holes in the crust, and pouring off the still molten metal; the crucible is found to be lined with crystals of Bi.

**Properties.**—Very lustrous; white with a slightly reddish tinge; very easily crystallises; brittle; diamagnetic, but not so when molten (Faraday, P. Suppl. 3, 1; Weber, P. 73, 241; 87, 145; Reich, P. 97, 283; Plücker, P. 72, 339; 76, 576; 81, 133). For thermo-electric behaviour v. Svanberg, C. R. 31, 250; Franz, P. 83, 374; Matteucci, C. R. 40, 541. Bi expands as it solidifies (for method of demonstrating this v. Böttger, D. P. J. 212, 441). May be distilled at a high temperature (over  $1100^\circ$ ) in an atmosphere of H. The atom of Bi is trivalent in the gaseous molecule  $\text{BiCl}_3$ . Bi forms numerous alloys most of which melt at low temperatures, and expand on solidification (v. BISMUTH ALLOYS or). The atomic weight of Bi has been determined (1) by finding V.D. of, and determining Cl in,  $\text{BiCl}_3$  (Dumas, A. Ch. [3] 55, 129 a. 176); (2) by oxidising Bi to  $\text{Bi}_2\text{O}_3$  by means of  $\text{HNO}_3$  (Schneider, P. 82, 303; J. pr. [2] 30, 237; Löwe, Fr. 22, 498; Marignac, A. Ch. [6] 1, 289); (3) by converting  $\text{Bi}_2\text{O}_3$  into sulphate (Marignac, l.c.). The exact value to be given to the at. w. of Bi is still doubtful; it is certainly not greater than 208. Bi is metallic in its chemical functions; it shows a marked tendency to form basic rather than normal salts; many of these basic salts may be represented as containing the group  $\text{BiO}$  e.g.  $\text{BiO.NO}_3$ ,  $(\text{BiO})_2\text{SO}_4$ , &c.; several oxychlorides and oxybromides are known; no hydride of Bi has yet been obtained; the oxides of Bi are salt-forming in their reactions with acids, none of them is an anhydride, but moist  $\text{Bi}_2\text{O}_3$  dissolves in very conc. boiling  $\text{KOH aq}$  probably with formation of compounds in which Bi acts as part of the negative radicle (v. BISMUTHIC OXIDE under BISMUTH, OXIDES or). Bi shows distinct analogies to As and Sb, also to the other members of Group V., in its chemical relations; for fuller discussion v. BISMUTH, CHEMICAL RELATIONS or. Bi salts are used in medicine; the alloys are used in printing, soldering, &c.

**Reactions.**—1. Very superficially oxidised in ordinary air; heated in air or oxygen burns to  $\text{Bi}_2\text{O}_3$ .—2. Decomposes steam at a red heat.—3. Combines directly with several elements, especially O, Cl, Br, I, S, Se, and Te:  $[\text{BiCl}]^2 = 90,630$  (Th. 2, 410);  $[\text{Bi}^+\text{O}]^2 = \text{abt. } 95,000$  (Woods, P. M. [4] 4, 370).—4. Scarcely acted on by hydrochloric acid dilute or conc.—4. With hot conc. sulphuric acid a basic sulphate is formed.—5. Quickly dissolved by nitric acid with formation of  $\text{Bi(NO}_3)_3$ .—6. Oxidised, but slowly and partially, by fusion with potassium nitrate or chlorate.

**Estimation.**—Generally as  $\text{Bi}_2\text{O}_3$ , after ppn. from a solution free from HCl and chlorides by excess of ammonium carbonate, and warming for some time; the pp. is washed, dried, and heated whereby  $\text{Bi}_2\text{O}_3$  is produced. Also by adding much water to a solution in as little HCl as possible, warming, collecting  $\text{BiOCl}$ , and drying at  $100^\circ\text{--}110^\circ$  (traces of Bi remain unppd.); the  $\text{BiOCl}$  may be reduced by heating with KCN, and the Bi weighed. Ppn. as  $\text{Bi}_2\text{S}_3$  and weighing is not to be recommended, as  $\text{Bi}_2\text{S}_3$  is easily oxidised in moist air. Volumetric

methods of estimating Bi, none of which, however, is altogether satisfactory, have been based on (1) ppn. of  $\text{Bi}(\text{IO}_3)_3$  from acetic acid solutions by a measured mass (excess) of  $\text{HIO}_3$  aq, and determination of residual  $\text{HIO}_3$  (Buisson a. Ferray, *M. S.* [3] 3, 900); (2) ppn. of Bi chromate from nearly neutral solutions by  $\text{K}_2\text{Cr}_2\text{O}_7$  aq or  $\text{K}_2\text{Cr}_2\text{O}_8$  aq; (3) pptn. of Bi phosphate by standardised  $\text{Na}_2\text{HPO}_4$  aq; (4) ppn. of Bi oxalate, conversion into basic oxalate by boiling water, and titration with  $\text{K}_2\text{MnO}_4$  aq; (5) ppn. of double oxalate of Bi and K by standardised  $\text{K}_2\text{C}_2\text{O}_4$  aq and determination of residual  $\text{K}_2\text{C}_2\text{O}_4$  by  $\text{K}_2\text{MnO}_4$  aq (Pattison Muir, *C. J.* 29, 483; 32, 674; 33, 70; (with Robbs) *C. J.* 41, 1).

**Chemical Relations of Bismuth.**—Bi is the highest known member of Group V.; this group contains the following elements:—

Even series	2	4	6	8	10	12
	N=14	V=51	Nb=91	Bi=112	Ta=182	
Odd series	3	5	7	9	11	13
	P=31	As=75	Sb=120	Br=160	Bi=208	

Taken as a whole these elements are negative and their compounds with H and O react as acids. As the group is ascended the negative characters become less marked until Bi is reached; omitting N, the oxides  $\text{M}_2\text{O}_3$  of the even series members, so far as known, are salt-forming in their reactions with acids; but in the odd series members these oxides, on the whole, are salt-forming only in their reactions with bases, until Series 9 is reached, when the character of the oxides  $\text{M}_2\text{O}_3$  becomes decidedly basic. The oxides  $\text{M}_2\text{O}_3$ , on the whole, are acid-forming, but the acidic functions of  $\text{Bi}_2\text{O}_3$  are very feeble. Salts formed from acids by replacement of H are obtained in the cases of V, Bi, Er, and Bi; but most of the salts of vanadium, and many of those of Bi, seem to contain groups of the form  $\text{M}_2\text{O}_3$ , acting as the more positive part of the salt; several salts of the normal type, e.g.  $\text{Bi}_2\text{SO}_4$ , are however known and several normal Er and Bi salts have been prepared. Vanadium is characterised by the great number of complex compounds into which it enters, sometimes as part of the positive, sometimes as part of the negative, group of the salt. Considering the compositions of the haloid, and oxyhaloid compounds, we find that, so far as investigation has gone, compounds of the form  $\text{MX}_3$  and  $\text{MOX}_3$ , where X is a halogen element, exist when M is any member of the group except Bi or As (N is omitted as there is much doubt concerning the composition of its haloid compounds), and in the case of As compounds of  $\text{AsF}_3$  with  $\text{KF}$ , &c., seem to exist; the compounds  $\text{BiBr}_3(\text{C}_2\text{H}_5)_3$  and  $\text{BiCl}_3(\text{C}_2\text{H}_5)_3$  are known as solids (Michaelis, *B.* 20, 52). The haloid compounds  $\text{BiX}_3$  are less easily oxidised than the corresponding compounds of P, As, or Sb. The basic character of the oxides of bismuth, the existence of many salts in which Bi acts as the metallic element, the stability of the haloid compounds  $\text{BiX}_3$ , and the non-existence of  $\text{BiX}_5$ , the non-existence of any compound in which  $\text{Bi}_2\text{S}_3$  acts as the negative radiolite; these, among other properties, show that Bi must be classed as the distinctly metallic element of Group V. But the feeble acidic functions of  $\text{Bi}_2\text{O}_3$  towards strong alkalis, the readiness with which so-called basic salts of bismuth are formed, the fact that  $\text{Bi}_2\text{O}_3$  and

$\text{Bi}_2\text{O}_5$  form no corresponding salts, the existence of several complex oxyhaloid compounds; these, among other properties, show that the general non-metallic character of Group V. to some extent belongs to Bi.

**Bismuth, Alloys of.** Bismuth alloys with many metals when melted with them; these alloys are characterised by low melting points, and many of them, by the expansion which they undergo as they cool after being melted. The most technically important alloys are:—*Newton's metal*; 8 parts Bi, 5 Pb, and 3 Zn, M.P. =  $94^\circ\text{F}$ ; *Rose's metal*; 5 Bi, 3 Pb, 2 Sn, M.P. =  $91^\circ\text{F}$ ; *Wood's metal*; 15 Bi, 8 Pb, 4 Sn, 3 Cd, M.P. =  $68^\circ\text{F}$ ; *Fusible metal*; 2 parts Bi, 1 Pb, 1 Sn, M.P. =  $93^\circ\text{F}$ ; this alloy expands from  $32^\circ$  to  $95^\circ$ , contracts gradually to  $131^\circ$  when its volume is less than at  $32^\circ$ , then expands to  $174^\circ$ , after which its expansion is uniform.

**Amalgams of Bi** are easily formed at ordinary temperatures. Alloys with copper are formed below the melting point of Cu; an alloy of 2 parts Bi with 1 part Cu begins to expand after solidification (Marx, *S.* 68, 470). An alloy of 3 parts Bi with 1 part iron is magnetic. Alloys of Bi and palladium are hard as steel; with 1 part spongy platinum Bi forms an easily fusible alloy which separates into Pt and Bi when fused at a low red heat. Bi does not alloy with zinc; on mixing melted Zn and Bi two layers are formed, one containing a little Bi and much Zn, the other much Bi and little Zn.

**Bismuth, Bromides of.** Only one bromide,  $\text{BiBr}_3$ , has been obtained with certainty; but many facts point to the existence of a lower bromide, probably  $\text{BiBr}_2$ .

**TRI-BROMIDE,  $\text{BiBr}_3$ .** (*Bi trichloride bromide*.) Mol. w. unknown, but probably as represented by formula. [210-215] (Pattison Muir, *C. J.* 29, 141). [Between  $454^\circ$  a. 498] (Carnelley a. Williams, *C. J.* 23, 283).

**Formation.**—1. By heating powdered Bi in  $\text{CO}_2$  charged with Br vapour. 2. By adding powdered Bi to a solution of Br in dry ether, and evaporating *in vacuo*.

**Preparation.**—1½ parts Br are allowed to flow, in small successive quantities, into 1 part powdered Bi in a small retort with the beak tilted upwards; when the mass is cool, the retort is very gently warmed for some days, and from time to time a few drops of Br are poured into the retort; the bromide forms in yellow crystals a little distance above the heated mass.

**Properties and Reactions.** Golden yellow crystals; S.G.  $\frac{5}{6}$ ; 5.4; very deliquescent; soluble in dry ether; decomposed by water to  $\text{BiOBr}$  and  $\text{HBr}$  aq; partially reduced to Bi by heating in hydrogen; heated with  $\text{Bi}_2\text{O}_3$  forms  $\text{BiOBr}$ ; by action of nitrogen oxides obtained by heating starch with  $\text{HNO}_3$  aq the oxybromide  $\text{Bi}_2\text{O}_5\text{Br}_2$  is produced; unchanged when heated in  $\text{CO}_2$  or  $\text{SO}_2$ ; reacts with ammonia, when heated in that gas, to form (1)  $\text{BiBr}_3\cdot 5\text{NH}_3$ , which is a straw-yellow powder, soluble in  $\text{HCl}$  aq and yielding  $\text{BiBr}_3\cdot 5\text{NH}_3\cdot \text{Cl}_2\text{H}_2\text{O}$  by evaporation over  $\text{H}_2\text{SO}_4$ ; (2) probably  $\text{BiBr}_3\cdot 2\text{NH}_3$ , an olive-green solid; (3) an ash-grey, crystalline, infusible, solid, probably  $\text{Bi}_2\text{N}_2\text{Br}_6$ . The compound  $2\text{BiBr}_3\cdot 5\text{NH}_3$  is

obtained (along with Bi) as a grayish-green powder, by heating  $\text{Bi}_2\text{O}_3 \cdot \text{Br}_2$  to dull redness in dry  $\text{NH}_3$ . (Pattison Muir, *C. J.* 29, 144; 16, 27). A solution of  $\text{BiBr}_3$  in saturated  $\text{KClAq}$  deposits crystals of  $\text{BiCl}_2 \cdot \text{Br} \cdot \text{K} \cdot 1\frac{1}{2} \text{H}_2\text{O}$  (Atkinson, *C. J.* 43, 292). Does not combine with Cl.

**Dibromide.**—Probably  $\text{BiBr}_2$  or  $\text{Bi}_2\text{Br}_4$ . In preparing  $\text{BiBr}_3$  dark grey crystals are formed if there is a deficit of Br; these contain Br nearly agreeing with the formula  $\text{BiBr}_2$ ; on heating they give Bi and  $\text{BiBr}_3$ . Weber (*P.* 107, 599) obtained a brown mass—probably a lower bromide than  $\text{BiBr}_3$ —by heating  $\text{BiBr}_3$  with Bi; Macivor (*C. N.* 30, 190) obtained a dark grey solid, melting at  $198^\circ\text{--}200^\circ$ , by heating Bi and Br.

**Bismuth, Chlorides of.** Two chlorides are known,  $\text{BiCl}_3$  and  $\text{Bi}_2\text{Cl}_4$ ; all attempts to form a chloride with more Cl than  $\text{BiCl}_3$  have failed. Both may be obtained by the direct combination of Bi and Cl;  $\text{Bi}_2\text{Cl}_4$  is separated into  $\text{BiCl}_3$ , Bi, and Cl, by heating;  $\text{BiCl}_3$  is reduced to  $\text{Bi}_2\text{Cl}_4$  by heating with Bi, or with  $\text{HgCl}_2$ .

**Trichloride.**  $\text{BiCl}_3$  (Bismuthous chloride). Mol. w. 314. ( $227^\circ$ ) (Pattison Muir, *C. J.* 29, 144). ( $427^\circ\text{--}439^\circ$ ) (Carnelley & Williams, *C. J.* 83, 281).

**Formation.**—1. By heating 1 part powdered Bi with 2 parts  $\text{HgCl}_2$  in a retort.—2. By dissolving  $\text{Bi}_2\text{O}_3$  in  $\text{HClAq}$ , evaporating to dryness, heating in air and then in a retort.—3. By heating  $\text{Bi}_2\text{O}_3$  in dry Cl.

**Preparation.**—Powdered Bi is heated in a current of dry Cl, in a retort with the beak tilted upwards and furnished with an exit tube passing into conc.  $\text{H}_2\text{SO}_4$ ; when a light yellow liquid has been formed, the stream of Cl is slackened and the retort is very gently heated for some time; crystals of  $\text{BiCl}_3$  sublime on to the upper parts of the vessel. The crystals may be distilled into small tubes in a current of dry N; the tubes are at once sealed.

**Properties and Reactions.**—White, very deliquescent, crystals, melting in Cl to a pale yellow liquid; S.G.  $10^\circ$  4.56; soluble in dry alcohol. Heated in air between two watch glasses part sublimes and an oxychloride— $\text{Bi}_2\text{O}_2\text{Cl}_2$  or  $\text{Bi}_2\text{O}_3\text{Cl}_2$ —remains. The same oxychloride is obtained by the action of nitrogen oxides (from starch and  $\text{HNO}_3\text{Aq}$ ) on  $\text{BiCl}_3$ . Heated in hydrogen  $\text{Bi}_2\text{Cl}_4$  and Bi are formed, at a higher temperature all the Cl is removed. Decomposed by water to  $\text{BiOCl}$  and  $\text{HClAq}$ ; the amount of change depends on the relative masses of  $\text{BiCl}_3$ ,  $\text{HCl}$ , and  $\text{H}_2\text{O}$ , and on the time; when the reacting bodies are mixed in the ratio  $\text{BiCl}_3 : 26\text{HCl} : 19,000 \text{H}_2\text{O}$  a little  $\text{BiCl}_3$  remains unchanged even after 14 days action (v. Pattison Muir, *C. J.* 35, 311; Ostwald, *J. pr.* [2] 12, 264). Heated with sulphur  $\text{Bi}_2\text{S}_3$  is formed (v. Bismuth sesquichloride). Not acted on by  $\text{CrO}_2\text{Cl}_2$ ; scarcely acted on by  $\text{SO}_2$ ; does not combine with Br (*P. M.*, *C. J.* 89, 83).

**Combinations.**—With ammonia to form (1)  $2\text{BiCl}_3 \cdot \text{NH}_3$ , a red, fusible, crystalline solid; (2)  $\text{BiCl}_3 \cdot 2\text{NH}_3$ , a greenish solid; (3)  $\text{BiCl}_3 \cdot 3\text{NH}_3$ , a white, volatile solid (Döhérain, *C. R.* 84, 724). These ammonio-chlorides by treatment with  $\text{HClAq}$  yield compounds of the form  $x\text{BiCl}_3 \cdot y\text{NH}_4\text{Cl}$ , where  $x$  varies from 1 to 2,

and  $y$  from 1 to 3. With potassium chloride forms  $\text{BiCl}_3 \cdot 2\text{KCl} \cdot 2\frac{1}{2}\text{H}_2\text{O}$ ; also with sodium chloride forms corresponding salt with  $3\text{H}_2\text{O}$ ; a solution of  $\text{BiCl}_3$  in hydrochloric acid when evaporated gives needles of  $\text{BiCl}_3 \cdot 2\text{HCl}$  (Jacquelin, *A. Ch.* [2] 62, 363).

**Dichloride.**—Probably  $\text{Bi}_2\text{Cl}_4$ . Mol. w. unknown.

**Formation.**—1. By gently heating  $\text{BiCl}_3$  in H; but the product is mixed with Bi and  $\text{BiCl}_3$ . 2. By heating  $\text{BiCl}_3$  with Bi (Weber, *P.* 107, 596).—3. By heating  $\text{BiCl}_3 \cdot x\text{NH}_4\text{Cl}$  in H to  $300^\circ$  (Schneider, *P.* 96, 130).

**Preparation.**—A very intimate mixture of 2 parts  $\text{HgCl}_2$  with 1 part extremely finely powdered Bi is heated to  $230^\circ\text{--}250^\circ$  in a closed tube for some time; the mixture melts to a dark brownish black liquid, and Hg (with a little Bi) collects at the bottom of the tube; the sides of the tube are tapped from time to time to make the Hg settle; after cooling the  $\text{BiCl}_3$  solidifies over the Hg, it is removed as quickly as possible to another tube—which is at once closed—and again melted; this process is repeated several times; nearly pure  $\text{Bi}_2\text{Cl}_4$ , containing a very little Hg and Bi, is finally obtained (Schneider, *P.* 96, 130).

**Properties and Reactions.**—Black, or nearly black, extremely deliquescent, solid; with water forms  $\text{BiOCl}$ ; with potash gives  $\text{Bi}_2\text{O}_3$ , which is quickly oxidised to  $\text{Bi}_2\text{O}_5 \cdot x\text{H}_2\text{O}$ ; with dilute mineral acids gives Bi salts and Bi; heated to about  $300^\circ$  gives  $\text{BiCl}_3$  and Bi.

**Bismuth, Cyanides and Ferrocyanides of, v. CYANIDES.**

**Bismuth, Fluoride of.** Only one fluoride of Bi has as yet been prepared (Pattison Muir, Hoffmeister and Robbs, *C. J.* 39, 33),  $\text{BiF}_3$ . Mol. w. unknown.

**Preparation.**—1.  $\text{Bi}_2\text{O}_3$  is added in small successive quantities to  $\text{HFAq}$  heated in a Pt dish until the oxide ceases to be dissolved; the liquid is decanted and evaporated at  $100^\circ$ ; the residue,  $\text{BiF}_3 \cdot 3\text{HF}$ , is warmed at about  $110^\circ\text{--}120^\circ$  in a closed Pt crucible until dry, and is then heated (in the closed crucible) so long as HF is evolved.—2. Excess of saturated  $\text{KFAq}$  is added to a solution of  $\text{Bi}(\text{NO}_3)_3$  in the minimum quantity of dilute  $\text{HNO}_3\text{Aq}$ , the pp. is thoroughly washed with boiling water, dried at  $100^\circ$ , and heated to dull redness in a closed Pt crucible.

**Properties.**—Grey, heavy, crystalline, solid. S.G.  $20^\circ$  5.33. Unacted on by water; insoluble in alcohol; scarcely changed or volatilised by heating to redness in open Pt dish; not oxidised by heating in nitrous oxides (from starch and  $\text{HNO}_3\text{Aq}$ ); dissolved, with decomposition, by hot  $\text{HCl}$ ,  $\text{HNO}_3$ , or  $\text{H}_2\text{SO}_4\text{Aq}$ . Combines with HF to form  $\text{BiF}_3 \cdot 3\text{HF}$  (v. *supra*) which is a crystalline, greyish-white, deliquescent solid, decomposed by boiling water to  $\text{BiOF}$  (v. Bismuth oxyfluoride).

**Bismuth, Haloid Compounds of.**  $\text{BiF}_3$ ;  $\text{BiCl}_3$ ,  $\text{Bi}_2\text{Cl}_4$ ;  $\text{BiBr}_3$  (?  $\text{Bi}_2\text{Br}_4$ );  $\text{BiI}_3$ . The V.D. of  $\text{BiCl}_3$  only has been determined; the other formulae are probably molecular.  $\text{BiCl}_3$  and  $\text{Bi}_2\text{Br}_4$  are decomposed by heat to Bi and  $\text{BiX}_3$ ; the others are unchanged when heated out of air; heated in air all except  $\text{BiF}_3$  are more or less oxidised,  $\text{BiCl}_3$  to the greatest, and  $\text{BiI}_3$  to the least, extent.  $\text{BiI}_3$  is a very stable com-

found (v. Bismuth, Fluorides of; Chlorides of; Oxides of; and Iodide of).

**Bismuth, Hydrated oxides, or hydroxides of, v. Bismuth, oxides of.**

**Bismuth, Iodide of,  $\text{BiI}_3$ .** Mol. w. unknown; probably as represented by formula.

**Formation.**—1. By heating an intimate mixture of 1 part  $\text{Bi}_2\text{S}_3$  with 14 parts I, in a large, loosely covered flask, and then heating the sublimed  $\text{BiI}_3$  at  $100^\circ$  to remove I (Schneider, P. 99, 470).—2. By dropping  $\text{BiONO}_3$  in dilute  $\text{HNO}_3\text{aq}$  into conc.  $\text{KIaq}$ , dissolving the brown pp. in fairly conc.  $\text{HIAq}$ , and ppg.  $\text{BiI}_3$  by as little water as possible (Ramel-berg, P. 48, 166), drying pp. at  $100^\circ$ , and removing free I by one or two washings with absolute alcohol.—3. By the action of  $\text{HIAq}$  on  $\text{Bi}_2\text{O}_3$ .

**Preparation.**—An intimate mixture of 1 part Bi with 2 parts I is gently heated in a flask with a long neck passing into another flask; the sublimate is finely powdered and again heated in the same way as before; this is repeated once or twice; and finally the mass is distilled in a fairly rapid current of dry  $\text{CO}_2$  (Weber, P. 14, 113 (slightly modified)).

**Properties and Reactions.**—(Pattison Muir, Hoffmeister, A. Robbs, C. J. 39, 33.) Dark grey, metal-like, lustrous, crystall. (probably hexagonal, Nicklès, C. R. 50, 872; S.G. 5.65. S. talcohol at  $20^\circ$ ) c. 3.5. Unchanged in air; heated in air a very little  $\text{Bi}_2\text{O}_3$  is formed. Unchanged by heating in *hydrogen*, or with *sulphur*, or in *sulphur dioxide*. Slowly changed to  $\text{BiOI}$  by a large quantity of cold water, more quickly by boiling water. Very partially converted into  $\text{BiOI}$  by heating in N oxides (from starch and  $\text{HNO}_3\text{aq}$ ).  $\text{BiI}_3$  is much more stable than either  $\text{BiCl}_3$  or  $\text{BiBr}_3$ .

**Combinations.**—With HI to form  $\text{BiI}_3$ ,  $\text{HI} \cdot \text{HI}_2\text{O}$  (Arppe, P. 41, 218). With MI (M = Na, K,  $\text{NH}_4$ ), and  $\text{MI}_2$  (M = Ca, Ba, Mg, Zn), to form double compounds isomorphous with the corresponding compounds of  $\text{SbI}_3$ ; obtained by direct combination of the iodides, or by acting on Bi with I in presence of the iodide MI or  $\text{MI}_2$ ; they are all deliquescent, and are easily resolved by water into their component iodides (Nicklès, C. R. 51, 1097; Linan, P. 111, 210).

**Bismuth, Oxides and hydrated oxides of.** Four oxides are known,  $\text{Bi}_2\text{O}_3$ ,  $\text{Bi}_2\text{O}_4$ ,  $\text{Bi}_2\text{O}_5$ ,  $\text{Bi}_2\text{O}_6$ ; as none has been gasified, the V.D. and hence the molecular weight of none is known. These oxides all react with acids to form the same series of salts,  $\text{BiX}_3$ , where  $\text{X} = \text{NO}_2$ ,  $\text{SO}_4$ ,  $\text{CO}_3$ , &c.; if much water is present, basic salts, usually of the form  $\text{BiOX}$ , are produced; in the reactions of  $\text{Bi}_2\text{O}_3$  with acids Bi is separated as metal; in the reactions of  $\text{Bi}_2\text{O}_4$  and  $\text{Bi}_2\text{O}_5$  oxygen is evolved.  $\text{Bi}_2\text{O}_3 \cdot \text{H}_2\text{O}$  is slightly soluble in very conc. boiling  $\text{KOHaq}$ , but no salts have been certainly obtained in which the acid radicle is composed of Bi and O.  $\text{Bi}_2\text{O}_3$  is easily oxidised to  $\text{Bi}_2\text{O}_4$ ;  $\text{Bi}_2\text{O}_4$  and  $\text{Bi}_2\text{O}_5$  are deoxidised to  $\text{Bi}_2\text{O}_3$  by heating in air or oxygen to about  $320^\circ$  and  $250^\circ$  respectively;  $\text{Bi}_2\text{O}_6$  is unchanged when heated in air or oxygen.  $\text{Bi}_2\text{O}_3$  is not hydrated by contact with water;  $\text{Bi}_2\text{O}_4$  and  $\text{Bi}_2\text{O}_5$  are hydrated in moist air, in contact with water they are partially and slowly deoxidised to hydrates of  $\text{Bi}_2\text{O}_3$ .

Vol. I.

The more important papers on the oxides and hydrated oxides of Bismuth follows:—1. On oxides containing less O than  $\text{Bi}_2\text{O}_3$ .—Thomson (Proc. Glasgow Phil. Soc. 1841-42, 4); Heints (P. 63, 55, 559); Schneider (P. 88, 49; 97, 480); Arppe (P. 61, 237); Vogel (Kästner's Archiv, 23, 86); Berzelius (Lehrbuch, 2, 574 (5th ed.)); Schiff (A. 119, 331); Pattison Muir (C. J. 32, 128).—2. On oxides containing more O than  $\text{Bi}_2\text{O}_3$ .—Jacquelin (1838) (J. pr. 14, 1); Heints (1841) (P. 63, 559); Arppe (1845) (P. 61, 237); Böttger (1858) (J. pr. 73, 494); Schröder (1862) (A. 121, 201); Boedeker (1862) (A. 123, 61); Wernicke (1870) (P. 141, 109); C. Hoffmann, (1884) (A. 223, 110); Pattison Muir (1876 to 1886) (C. J. 29, 144; 31, 21; 32, 128; *ibid.* 39, 21 [with Hoffmeister, A. Robbs]; 51, 77 [with Carnegie]); Haschrook (1887) (B. 20, 213).—3. On  $\text{Bi}_2\text{O}_4$ .—Bonsdorff (P. 41, 305); Fuchs (S. 67, 429); Stromeyer (P. 26, 553); Liebig (Mag. Pharm. 35, 114); Pattison Muir (l.c.).

**Hydrobismuthous oxide.**  $\text{Bi}_2\text{O}_3$  (Bismuth suboxide. Bismuth dioxide. Black oxide of bismuth).

**Preparation.**—A mixture of 1 part  $\text{SnCl}_4$  and 2.5 parts  $\text{Bi}_2\text{O}_3$  is dissolved in as little fairly conc.  $\text{HClaq}$  as possible, the solution is poured into an excess of  $\text{KOHaq}$  (about 1 KOH in 10  $\text{H}_2\text{O}$ ) in a stoppered flask so that the flask is nearly filled with the liquid; the stopper is placed in the flask, and the black pp. is allowed to settle; the pp. is washed with cold  $\text{KOHaq}$  (in air-free water) less concentrated than that used in the ppm. the flask being each time nearly filled with the liquid, and then with air-free water; it is then quickly dried by pressing between filter paper, and placed over  $\text{H}_2\text{SO}_4$  *in vacuo* (Schneider, P. 88, 45).

**Properties and Reactions.**—Black, crystalline, powder; begins to oxidise in air at about  $180^\circ$ ; at  $200^\circ$  heat quickly oxidised to  $\text{Bi}_2\text{O}_3$ ; oxidised to  $\text{Bi}_2\text{O}_4 \cdot \text{H}_2\text{O}$  and  $\text{Bi}_2\text{O}_5 \cdot \text{H}_2\text{O}$  by boiling with  $\text{KOHaq}$  and Br; oxidised to  $\text{Bi}_2\text{O}_5 \cdot \text{H}_2\text{O}$  by  $\text{KMnO}_4\text{aq}$ ; when moist,  $\text{Bi}_2\text{O}_3$  is rapidly oxidised in air to  $\text{Bi}_2\text{O}_4 \cdot \text{H}_2\text{O}$ ; oxidised by contact with a very little  $\text{HNO}_3\text{aq}$ , decomposed to  $\text{Bi}_2\text{O}_5\text{NO}_2$  and Bi by more  $\text{HNO}_3\text{aq}$ , dissolved entirely by a considerable quantity of the same acid; decomposed by  $\text{HClaq}$  or  $\text{H}_2\text{SO}_4\text{aq}$  to  $\text{BiCl}_3$  or Bi sulphate, and Br; deoxidised, to Bi, by heating in H or CO; decomposed by boiling  $\text{KOHaq}$  with formation of Bi (Schneider, l.c.; Pattison Muir, l.c.). No hydrate of  $\text{Bi}_2\text{O}_3$  has been definitely obtained. Solution of  $\text{Bi}_2\text{O}_3$  in tartaric acid is said to give  $\text{Bi}_2\text{S}_3$  by reaction with  $\text{H}_2\text{S}$  (Schneider), v. Bismuth disulphide.

**Bismuthous oxide.**  $\text{Bi}_2\text{O}_4$  (Bismuth trioxide). S.H. (12-97)-0609 (Regnault, A. Ch. [3] 1, 129). S.G. 8.21 (Herapath, P.M. 64, 321); 8.08 (Playfair & Joule, C. J. Mem. 3, 57). Occurs native generally associated with oxide of iron.

**Formation.**—1. By heating Bi in air or O.—2. By ppg. Bi nitrate or chloride solution by excess of alkali and boiling; thus prepared always contains some oxynitrate or oxychloride.

**Preparation.**—1. Basic Bi nitrate, obtained by ppg. solution of Bi in  $\text{HNO}_3\text{aq}$  by large excess of water, is heated in a Pt dish with constant agitation until oxides of N are no longer evolved. If this oxide is fused with KOH it crystallises on cooling in rhombic

L L

prisms,  $n_D^{20} = 1.685$ ; 1:1064 (Nordenakjöld, P. 114, 513).—2.  $\text{BiOCl}$  (g. c.) is shaken for some time with very conc.  $\text{KOH}$  aq. until the change to  $\text{Bi}_2\text{O}_3$  and  $\text{KCl}$  is complete; the  $\text{Bi}_2\text{O}_3$  is washed with cold water until quite free from  $\text{KOH}$  and  $\text{KCl}$  and dried; the oxide may be thus obtained in distinct crystals.

**Properties and Reactions.**—Heavy, yellowish-white, solid; unchanged by heating in air or oxygen. Dissolves in acids to form Bi salts (v. BISMUTH, SALTS *op.*).  $\text{HFAg}$  heated with  $\text{Bi}_2\text{O}_3$  dissolves part of it as  $\text{BiF}_3 \cdot 3\text{HF}$  and converts the rest into  $\text{BiOF} \cdot 2\text{HF}$ ;  $\text{HXAq}$  ( $\text{X} = \text{Cl}$  or  $\text{Br}$ ) added to  $\text{Bi}_2\text{O}_3$  little by little converts the whole of the Bi into  $\text{BX}$ , on addition of more  $\text{HXAq}$  the  $\text{BiOX}$  dissolves as  $\text{BiX}_3$ ; with a little  $\text{HIAq}$   $\text{BiI}_3$  is alone formed, if very dilute  $\text{HIAq}$  is added and the temperature is raised  $\text{BiOI}$  only is produced, with considerable excess of fairly conc.  $\text{HIAq}$   $\text{BiI}_3$  is formed and dissolved. Heated in chlorine,  $\text{BiCl}_3$  is formed; with bromine  $\text{BiBr}_3$  and  $\text{Bi}_2\text{O}_3 \cdot \text{Br}_2$  are produced. Heated in carbon monoxide reduction begins at about  $200^\circ$ , and in hydrogen at about  $210^\circ$ .  $\text{Bi}_2\text{O}_3$  is not hydrated in moist air; nor is it altered by contact with water. Unchanged by heating in nitrogen. Oxidised to  $\text{Bi}_2\text{O}_5$  and  $\text{Bi}_2\text{O}_6$  by action of chlorine in presence of much hot  $\text{KOH}$  aq.; scarcely oxidised by  $\text{KMnO}_4$  aq. (v. further HYPOBISMUTHIC, and BISMUTHIC, *oxides*).

**HYDRATED BISMUTHOUS OXIDE.**  $\text{Bi}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ ;  $x = 1, 2$ , and  $3$ . The hydrate with  $2\text{H}_2\text{O}$  is obtained by dissolving  $\text{Bi}_2\text{O}_3 \cdot \text{H}_2\text{O}$  in conc.  $\text{HCl}$  aq. pp. by  $\text{KOH}$  aq. and drying over  $\text{H}_2\text{SO}_4$  in *vacuo*; the hydrate with  $\text{H}_2\text{O}$  is obtained by dissolving  $\text{Bi}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$  in conc.  $\text{H}_2\text{SO}_4$ , reducing by  $\text{SO}_2$  pp. by  $\text{KOH}$  aq. and drying as before (P. M., C. J. 32, 131).  $\text{Bi}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$  is very difficult to obtain quite free from oxy-salts and  $\text{Bi}_2\text{O}_3$  pp. formed by adding  $\text{KOH}$  aq. to  $\text{Bi}_2\text{O}_3$  in  $\text{HCl}$ ,  $\text{HNO}_3$ , or  $\text{H}_2\text{SO}_4$ , and washing with cold water, always contain basic chloride, &c.; if washed with hot water they contain  $\text{Bi}_2\text{O}_3$ . Nearly pure  $\text{Bi}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$  is obtained by dissolving  $\text{Bi}_2\text{O}_3$  in the minimum of  $\text{HNO}_3$  aq. pouring into excess of conc.  $\text{NH}_3$  aq. washing with cold water until the washings contain no nitrates, then repeatedly agitating with very dilute  $\text{Na}_2\text{CO}_3$  aq. (to decompose traces of basic nitrates), again washing repeatedly with cold water, and drying in *vacuo* over  $\text{H}_2\text{SO}_4$ . The hydrates of  $\text{Bi}_2\text{O}_3$  are white solids, easily dehydrated by heat, partially even by contact with hot water;  $\text{Bi}_2\text{O}_3$  does not directly combine with water. The hydrates behave towards acids and oxidisers similarly to  $\text{Bi}_2\text{O}_3$ . None of these hydrates shows the slightest indications of acidic functions. Thomsen gives the thermal values  $[\text{Bi}^\circ, \text{O}^\circ, 3\text{H}_2\text{O}] = 137,710$ ;  $[\text{BiO}^\circ\text{H}^\circ, \text{HCl}$  aq.] =  $14,140$ , with formation of  $\text{BiOCl} + 2\text{H}_2\text{O}$  aq. (*Th.* 2, 244).

**HYPOBISMUTHIC OXIDE, AND HYDRATES.**  $\text{Bi}_2\text{O}_3$ ;  $\text{Bi}_2\text{O}_3 \cdot \text{H}_2\text{O}$ ;  $\text{Bi}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$  (Arppe, Schröder, Böttger, Wernicke, Pattison Muir). **Preparation of  $\text{Bi}_2\text{O}_3$ .**— $\text{Bi}_2\text{O}_3$  is suspended in  $\text{KOH}$  aq., S.G. abt. 1.35, the liquid is kept nearly boiling, and  $\text{Cl}$  is passed in until the solid is dark chocolate-red and quite homogeneous to the eye; the solid is washed with hot water until the washings are neutral to litmus, kept in contact with dilute  $\text{HNO}_3$  aq. (1 conc. acid to abt. 20 water) until the

colour of the solid has become brownish-yellow (12–16 hours) (to dissolve any  $\text{Bi}_2\text{O}_3$  and reduce any  $\text{Bi}_2\text{O}_3$ ), washed free from acid, and boiled with conc.  $\text{NaClO}_3$  aq. (to reoxidise any traces of  $\text{Bi}_2\text{O}_3$ ) until a heavy, yellow-brown, powder is formed which settles quickly; this powder is washed with hot water until quite free from alkali and  $\text{Cl}$ , and dried at  $180^\circ$ .

**Hydrates.**—If the drying is conducted over  $\text{H}_2\text{SO}_4$  the hydrate  $\text{Bi}_2\text{O}_3 \cdot \text{H}_2\text{O}$  is obtained. If  $\text{Bi}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$  (v. *inf.*) is treated with warm  $\text{HNO}_3$  aq. until the colour is orange-yellow, washed, and dried over  $\text{H}_2\text{SO}_4$ , the hydrate  $\text{Bi}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$  is obtained. These hydrates are also formed, the first by the action of ordinary air on  $\text{Bi}_2\text{O}_3$ , and the second (with  $2\text{H}_2\text{O}$ ) by the action of moist air on  $\text{Bi}_2\text{O}_3$ ; they part with their water of hydration at about  $150^\circ$ .

**Properties and Reactions.**— $\text{Bi}_2\text{O}_3$  is a brownish-yellow solid; S.G.  $\frac{29^\circ}{20^\circ}$  5.6; d-oxidised (to  $\text{Bi}_2\text{O}_5$ ) and dissolved by fairly conc.  $\text{HNO}_3$  aq. or  $\text{HCl}$  aq. more slowly by conc.  $\text{H}_2\text{SO}_4$ ; slightly deoxidised by contact with water in direct sunlight, oxidised to  $\text{Bi}_2\text{O}_5 \cdot x\text{H}_2\text{O}$  by  $\text{Cl}$  in presence of hot conc.  $\text{KOH}$  aq.; is not oxidised by ozonised  $\text{O}$  at  $100^\circ$ ;  $140^\circ$ ; heated in  $\text{Cl}$  gives  $\text{BiCl}_3$  and a little  $\text{Bi}_2\text{O}_3 \cdot \text{Cl}_2$ ; heated in  $\text{Br}$  gives  $\text{BiBr}_3$  and considerable quantity of  $\text{Bi}_2\text{O}_3 \cdot \text{Br}_2$ . Heated in  $\text{CO}$  reduction begins at abt.  $105^\circ$  and the change to  $\text{Bi}_2\text{O}_3$  is complete at about  $245^\circ$ – $250^\circ$ ; with  $\text{H}$  the corresponding temperatures are abt.  $200^\circ$  and  $265^\circ$ , respectively; heated in air or in  $\text{O}$  the temperatures are abt.  $210^\circ$  and  $320^\circ$ , respectively. Neither of the hydrates exhibits any decided acidic functions.

**BISMUTHIC OXIDE, AND HYDRATE.**  $\text{Bi}_2\text{O}_3$  (Bismuth peroxide).  $\text{Bi}_2\text{O}_5 \cdot \text{H}_2\text{O}$  (Bismuthic acid). S.G.  $\text{Bi}_2\text{O}_5$  5.917 (Brauner a. Watts, P.M. 1881, 62). S.V.S. 42. S.G.  $\text{Bi}_2\text{O}_5 \cdot \text{H}_2\text{O}$  5.75.

**Preparation.**— $\text{Bi}_2\text{O}_3$  or  $\text{Bi}_2\text{O}_3 \cdot \text{H}_2\text{O}$  or  $\text{BiOCl}$  is suspended in about 10 parts of conc.  $\text{KOH}$  aq., S.G. about 1.38, the liquid is kept nearly boiling and  $\text{Cl}$  is passed in until a dark-red homogeneous solid is formed; this solid is washed with hot water until the washings do not change the colour of red litmus paper and every trace of chloride is removed, it is then warmed for a very short time with a little conc.  $\text{HNO}_3$  aq. until its colour is scarlet, washed repeatedly and quickly with dilute  $\text{HNO}_3$  aq. each quantity of acid being more dilute than the preceding, and then with cold water until every trace of acid is removed. If the solid is now dried over  $\text{H}_2\text{SO}_4$ ,  $\text{Bi}_2\text{O}_5 \cdot \text{H}_2\text{O}$  is obtained; if this is dried at  $120^\circ$   $\text{Bi}_2\text{O}_5$  remains (Pattison Muir, C. J. 39, 22).

**Properties and Reactions.**—A red, heavy powder; combines with water to form  $\text{Bi}_2\text{O}_5 \cdot \text{H}_2\text{O}$ ; in contact with much water is slowly deoxidised with production of hydrates of  $\text{Bi}_2\text{O}_3$  and  $\text{Bi}_2\text{O}_3$ ; also deoxidised by hot dilute  $\text{HNO}_3$  aq. giving first  $\text{Bi}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$  and then hydrates of  $\text{Bi}_2\text{O}_3$ . Deoxidised to  $\text{Bi}_2\text{O}_3$  by heating in current of air or oxygen at about  $250^\circ$ , and to  $\text{Bi}_2\text{O}_3$  by heating in the same gases to about  $305^\circ$ ; reduction in  $\text{CO}$  begins at about  $70^\circ$ , in  $\text{H}$  at about  $100^\circ$ ; reduction to  $\text{Bi}_2\text{O}_3$  is complete in  $\text{H}$  current at about  $215^\circ$ , and to  $\text{Bi}_2\text{O}_3$  at about  $255^\circ$ . Reacts with  $\text{Cl}$ , and  $\text{Br}$ , to give  $\text{BiCl}_3$  and a little  $\text{Bi}_2\text{O}_3 \cdot \text{Cl}_2$ , and  $\text{BiBr}_3$  and a little  $\text{Bi}_2\text{O}_3 \cdot \text{Br}_2$ .

respectively. Does not exhibit any decided acidic functions;  $\text{Bi}_2\text{O}_3 \cdot \text{H}_2\text{O}$ , however, dissolves in about 100 parts of boiling KOHAq so concentrated that solidification begins the moment the lamp is removed; on cooling, dissolving in as little water as possible, and nearly neutralising by HClAq (or by exposure to air) yellowish-white solids are obtained from which all potash is removed only by very long-continued washing with boiling water. The solids dried at  $100^\circ$  contain a little water, Bi, and generally rather more O than is required by  $\text{Bi}_2\text{O}_3$ . Solutions of  $\text{Bi}_2\text{O}_3 \cdot \text{H}_2\text{O}$  in very conc. boiling KOHAq, therefore, probably contain compounds of the form  $x\text{Bi}_2\text{O}_3 \cdot y\text{K}_2\text{O}$ . In the preparation of  $\text{Bi}_2\text{O}_3$ , the very conc. KOHAq dissolves a little of the  $\text{Bi}_2\text{O}_3$ , as this is formed; on nearly neutralising with HClAq a white pp. is obtained, which, after long-continued washing with boiling water, consists of  $\text{Bi}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$  (Pattison Muir & Carnegie, C. J. 51, 77). In the preparation of  $\text{Bi}_2\text{O}_3$ , a portion of the potash is very obstinately retained; the whole of the potash can scarcely be removed by washing with boiling water; compounds of the form  $x\text{Bi}_2\text{O}_3 \cdot y\text{K}_2\text{O}$  are probably formed, but every attempt to isolate these bodies has failed.

**Bismuth, Oxyhaloid compounds of.** Oxybromides, oxychlorides, oxyiodides, and an oxyfluoride, of bismuth have been prepared. All the haloid compounds  $\text{BiX}_3$ , where X = Cl, Br, or I, are oxidised by heating in air; only a very little  $\text{BiOI}$  is produced by long continued heating  $\text{BiI}_3$ ;  $\text{BiBr}_3$  gives  $\text{Bi}_2\text{O}_3 \cdot \text{Br}_2$ , as  $\text{BiCl}_3$  gives  $\text{Bi}_2\text{O}_3 \cdot \text{Cl}_2$ . The same oxyhaloid compounds are formed by the reaction between N oxides, (from starch and hot  $\text{HNO}_3$ aq) and hot  $\text{BiX}_3$ ; the oxidation is carried furthest in the case of  $\text{BiBr}_3$ , in this case the whole or nearly the whole of the haloid compound may be oxidised. The most stable haloid compounds towards oxidisers are  $\text{BiF}_3$  and  $\text{BiI}_3$ .

**Oxybromides.** Three oxybromides are known:  $\text{BiOBr}$ ,  $\text{Bi}_2\text{O}_3 \cdot \text{Br}_2$ , and  $\text{Bi}_2\text{O}_3 \cdot \text{Br}_2$ .

**Bismuthyl bromide,  $\text{BiOBr}$ ,** is produced by the action of water on  $\text{BiBr}_3$ ; or by heating together  $\text{Bi}_2\text{O}_3$  and  $\text{BiBr}_3$ ; or by dissolving  $\text{Bi}_2\text{O}_3$  in  $\text{HBr}$ aq ( $\text{BiBr}_3$  is formed in solution) and adding  $\text{Bi}_2\text{O}_3$  little by little. It is a white amorphous powder; S.G.  $\frac{20}{20}$  6.7; insoluble in water; unchanged when heated to redness; mixed with charcoal and heated in dry Cl,  $\text{BiCl}_3$  is formed; reacts with cold HClAq to form  $\text{BiCl}_3$  and  $\text{BiBr}_3$ , with cold HFAq to form  $\text{BiI}_3$  and  $\text{HBr}$ aq, and with hot HFAq to form  $\text{BiBr}_3$ ,  $\text{BiOF}$  and  $\text{BiF}_3 \cdot 3\text{HF}$ .  $\text{BiOBr}$  heated in  $\text{NH}_3$  is reduced to Bi, and a little  $x\text{BiBr}_3 \cdot y\text{NH}_3$  is formed,  $x$  probably = 2 and  $y$  probably = 5 (Pattison Muir, C. J. 29, 144).

The oxybromide  $\text{Bi}_2\text{O}_3 \cdot \text{Br}_2$  is produced by heating dry  $\text{Bi}_2\text{O}_3$  with excess of Br for some hours and removing uncombined Br by warming in free contact with air. It is a cream-coloured, non-deliquescent, amorphous powder: unchanged by heating in air; unacted on by water; dissolved by warm HClAq and  $\text{HNO}_3$ aq (P. M., C. J. 31, 24).

The oxybromide  $\text{Bi}_2\text{O}_3 \cdot \text{Br}_2$  is produced (1) by slowly subliming  $\text{BiBr}_3$  in contact with a little air; (2) by passing N oxides obtained by heating starch and  $\text{HNO}_3$ aq into melted  $\text{BiBr}_3$ ;

in the first reaction only a little of the  $\text{BiBr}_3$  is oxidised, in the second reaction most of the  $\text{BiBr}_3$  is oxidised. In either case the product is washed with water and dried at  $100^\circ$ . This oxybromide is a grey, lustrous, crystalline powder; unchanged by water, or by heating to redness; soluble in HClAq and conc.  $\text{HNO}_3$ aq; slowly reduced by H, finally giving Br; heated in dry  $\text{NH}_3$ , Bi remains, and a greyish-green sublimate of  $2\text{BiBr}_3 \cdot 5\text{NH}_3$  is formed (P. M., C. J. 30, 12; 31, 24; 32, 40).

**Oxychlorides.** Three oxychlorides,  $\text{BiOCl}$ ,  $\text{Bi}_2\text{O}_3 \cdot \text{Cl}_2$ ,  $\text{Bi}_2\text{O}_3 \cdot \text{Cl}_2$  (or  $\text{Bi}_2\text{O}_3 \cdot \text{Cl}_2$ ), are known.

**Bismuthyl chloride,  $\text{BiOCl}$ ,** is formed by adding water to  $\text{BiCl}_3$  in a little HClAq; or by pouring  $\text{Bi}_2\text{NO}_3$  in  $\text{HNO}_3$ aq into dilute NaClAq; or by reacting on excess of  $\text{Bi}_2\text{O}_3$  with very dilute HClAq; or by digesting a solution of  $\text{BiCl}_3$  in HClAq with excess of  $\text{Bi}_2\text{O}_3$ . The pp. is washed with cold water and dried at  $100^\circ$ . This compound is a white, lustrous, crystalline powder (known commercially as 'pearl white') S.G.  $\frac{20}{20}$  7.2. Reacts with cold  $\text{HBr}$ aq to give  $\text{BiCl}_3$  and  $\text{HBr}$ ; with cold HIAq to give  $\text{BiCl}_3$  and  $\text{HI}$ ; with hot HFAq to form  $\text{BiCl}_3$ ,  $\text{BiOF}$ , and  $\text{BiF}_3 \cdot 3\text{HF}$ . Reduced to  $\text{BiCl}_3$  by heating with charcoal in dry Cl (Jacquelin, J. pr. 14, 1; Arppe, P. 64, 237; Oosten, P. 110, 128; Heintz, P. 63, 55; Pattison Muir, C. J. 39, 37).

The oxychloride  $\text{Bi}_2\text{O}_3 \cdot \text{Cl}_2$  is said to be produced by heating  $\text{BiOCl}$  to redness (Arppe).

The oxychloride  $\text{Bi}_2\text{O}_3 \cdot \text{Cl}_2$  is formed in small quantities by slowly subliming  $\text{BiCl}_3$  in contact with a little air, and in large quantities by passing N oxides (by heating starch with  $\text{HNO}_3$ aq) into melted  $\text{BiCl}_3$ . The analytical numbers agree fairly with  $\text{Bi}_2\text{O}_3 \cdot \text{Cl}_2$  and also with  $\text{Bi}_2\text{O}_3 \cdot \text{Cl}_2$ . The compound is a yellowish-white, hard, crystalline, solid; unchanged in air, or by water, or by heating to redness; soluble in hot HClAq or  $\text{HNO}_3$ aq; boiled with KOHAq,  $\text{Bi}_2\text{O}_3$  and  $\text{NaCl}$ aq are formed (P. M., C. J. 32, 40).

**Oxyfluoride.** Only one is known. **Bismuthyl fluoride,  $\text{BiOF}$ ,** is obtained by heating  $\text{Bi}_2\text{O}_3$  with large excess of HFAq so long as any reaction occurs, boiling the residue with water until every trace of acid is removed, and drying at  $100^\circ$ ; if the washing is conducted with cold water until nearly neutral,  $\text{BiOF} \cdot 2\text{HF}$  remains; when this is strongly heated in a closed Pt crucible,  $\text{BiOF}$  is obtained in crystalline form. The liquid obtained by boiling  $\text{Bi}_2\text{O}_3$  with HFAq evaporated at  $100^\circ$  gives  $\text{BiF}_3 \cdot 3\text{HF}$ ; when this salt is boiled with water it is slowly decomposed to  $\text{BiOF}$ .  $\text{BiOF}$  is a heavy, white, crystalline, powder; S.G.  $\frac{20}{20}$  7.55. With HF it forms the double compound  $\text{BiOF} \cdot 2\text{HF}$ . Reacts with cold HClAq to form  $\text{BiCl}_3$  and HFAq; with  $\text{HBr}$ aq to form  $\text{BiBr}_3$  and HFAq; with HIAq to form  $\text{BiI}_3$  and HFAq (P. M., Hoffmeister & Robbs, C. J. 39, 21).

**Oxybromides.** **Bismuthyl iodide,  $\text{BiOI}$ ,** is produced by boiling  $\text{BiI}_3$  with  $\text{H}_2\text{O}$  in small quantities, by subliming  $\text{BiI}_3$  in air; or, also in small quantities only, by reacting with N oxides (from starch and hot  $\text{HNO}_3$ aq) on hot  $\text{BiI}_3$ .  $\text{BiOI}$  is a heavy, red, crystalline powder, unchanged by water, or by heating in air; by long-continued heating to bright redness in air a very little  $\text{Bi}_2\text{O}_3$  is formed; reacts with HClAq,  $\text{HBr}$ aq, and HFAq, similarly to bismuthyl chloride

and bromide (Schneider, *V.*, *pp.* 74, 424; P. M., H. a. R., *loc.*).

Another oxyiodide, probably  $8\text{BiOI} \cdot 4\text{Bi}_2\text{O}_3$ , is obtained as a yellow powder by pouring a dilute solution of  $\text{BiONO}_3$  into  $\text{KIAg}$  mixed with  $\text{NaC}_2\text{H}_3\text{O}_2$  Aq (Fletcher & Cooper, *Ph.* 1842).

**Bismuth, Oxysulphide of.** According to Hermann (*J.*, *pp.* 75, 452) the compound  $\text{Bi}_2\text{O}_3\text{S}_3$  is formed by heating 1 part S with 4.55 parts  $\text{Bi}_2\text{O}_3$  to low redness in a retort; S.G. 6.3. A compound of Bi, S, and O, occurs as *Karelinite* (said to be  $\text{Bi}_2\text{O}_3\text{S}$ ).

**Bismuth, Phosphide of.** No definite compound has been isolated. Berzelius (*Lehrbuch*, 2, 582 [5th ed.]) says the two elements do not unite directly, but that a phosphide is formed by leading  $\text{PH}_3$  into  $\text{BiONO}_3$  solution.

**Bismuth, Salts of.** These compounds are obtained in a few cases by the reaction between Bi and an acid, *e.g.*  $\text{BiONO}_3$ , but more generally by using  $\text{Bi}_2\text{O}_3 \cdot \text{H}_2\text{O}$  in place of Bi, or by double decomposition from  $\text{BiONO}_3$  in  $\text{HNO}_3$  Aq or  $\text{BiCl}_3$  in  $\text{HCl}$  Aq. Bismuth salts are insoluble in water; they are decomposed by water with production of so-called basic salts: the salt of Bi may indeed be arranged in two classes, normal and basic, as types of which may be taken the nitrates  $\text{BiONO}_3$  and  $\text{Bi(OH)}_2\text{NO}_3$ , respectively. Many of these basic salts are most simply regarded as derived from acids by replacement of H by BiO; they are often called bismuthyl salts; other basic salts, however, at present at any rate, are best represented as compounds of acid-forming oxides with  $\text{Bi}_2\text{O}_3$ . All the basic nitrates for instance, and many of these salts are known, belong to the general form  $x\text{Bi}_2\text{O}_3 \cdot y\text{NO}_3 \cdot z\text{H}_2\text{O}$ . The salts obtained by reactions between acids and the oxides  $\text{Bi}_2\text{O}_3$  and  $\text{Bi}_2\text{O}_5$  are the same as those which are formed when  $\text{Bi}_2\text{O}_3$  is used. The more important salts of Bi are the *nitrates*, and *sulphates*, also *bromate*, *chlorate*, *arsenate*, *phosphates*, *tartrates*, &c. (*v.* NITRATES, SULPHATES, &c. &c.).

**Bismuth, Selenide of.**  $\text{Bi}_2\text{Se}_3$ . Black, lustrous, metal-like, powder; S.G. 6.82. Obtained by passing H<sub>2</sub>Se into  $\text{BiONO}_3$  in as little  $\text{HNO}_3$  Aq as possible, or by heating together 1 part Se and 1.8 parts Bi, and repeatedly melting the product in contact with Se. Insoluble in solutions of alkalis or alkali-sulphides; decomposed by  $\text{HNO}_3$  Aq; gives up Se when heated. Combines with  $\text{BiCl}_3$  (*v. infra*) (Berzelius; Schneider, *P.*, 94, 628).

**Bismuth, Selenochloride of.**  $\text{BiSeCl}$ . (*=*  $\text{Bi}_2\text{Se}_3 \cdot \text{BiCl}_3$ ). Formed by adding powdered  $\text{Bi}_2\text{Se}_3$  to molten  $2\text{NH}_4\text{Cl} \cdot \text{BiCl}_3$ . Steel-grey, needle-shaped, crystals. Heated in  $\text{CO}_2$  is separated into  $\text{Bi}_2\text{Se}_3$  and  $\text{BiCl}_3$  (Schneider, *loc.*).

**Bismuth, Sulphide of.** One well-marked sulphide of Bi,  $\text{Bi}_2\text{S}_3$ , is known; another,  $\text{Bi}_2\text{S}_5$ , corresponding to the oxide  $\text{Bi}_2\text{O}_5$ , probably exists. Attempts to prepare a sulphide with more S than  $\text{Bi}_2\text{S}_5$  have failed (Pattison Muir, *C. J.* 33, 192). Sulphide of bismuth does not react with more positive sulphides as a salt-forming compound (comp. Schneider, *Z.* [2] 5, 680 with P. M., *C. J.* 33, 192).

**Bismuth, Trisulphide.**  $\text{Bi}_2\text{S}_3$ . Occurs native as *bismuth glance*. S.G. 6.5. Rhombic forms,  $a:b:c = 1:0.984:1$ ; isomorphous with  $\text{As}_2\text{S}_3$ , and

$\text{Sb}_2\text{S}_3$ . Obtained by heating a mixture of 1 part S with 4.1 parts Bi till a gray crystalline mass is formed, and then repeatedly heating this with a little S; also by passing  $\text{H}_2\text{S}$  into an acid solution of a Bi salt. If the pp. thus obtained is heated with an alkali-sulphide solution to  $200^\circ$  the  $\text{Bi}_2\text{S}_3$  is said to become crystalline. Steel-grey, crystalline, lustrous, solid; strongly heated it is separated into Bi and S; unacted on by alkali or alkali-sulphide solutions.

**Bismuth Disulphide.**  $2\text{Bi}_2\text{S}_3 \cdot \text{H}_2\text{O}$ . Said to be ppd. by  $\text{H}_2\text{S}$  from alkaline solutions of  $\text{Bi}_2\text{O}_3$ . Schneider (*P.* 97, 480) dissolved 8 grams Bi tartrate in the necessary quantity of  $\text{KOH}$  Aq, added air-free water to make up to 1500 c.c., then 2 grams  $\text{SnCl}_4$  in  $\text{KOH}$  Aq, and passed in air-free  $\text{H}_2\text{S}$  until the liquid became colourless. He washed the black pp. with  $\text{KOH}$  Aq and then with  $\text{H}_2\text{O}$  (air-free), and dried at  $100^\circ$ . A black powder; becomes lustrous by compression; decomposed by heating into Bi and  $\text{Bi}_2\text{S}_3$ , by  $\text{HCl}$  Aq into Bi,  $\text{BiCl}_3$ , and  $\text{H}_2\text{S}$ .

**Bismuth, Sulphochloride of.** *v.* BISMUTH, THIO-HALOID COMPOUNDS OF.

**Bismuth, Sulphoiodide of.** *v.* BISMUTH, THIO-HALOID COMPOUNDS OF.

**Bismuth, Sulphocyanide of.**  $\text{Bi}(\text{SCN})_3$ , *v.* CYANIDES.

**Bismuth, Telluride of.** No definite compound has been isolated; *telluric bismuth*, approximately  $\text{Bi}_2\text{S}_3 \cdot 2\text{Bi}_2\text{Te}_3$ , occurs native. According to Berzelius (*Lehrbuch*, 2, 583 [5th ed.]) the two elements may be melted together in all proportions.

**Bismuth, Thiohaloid compounds of.** Only two are known:  $\text{BiSCl}$  and  $\text{BiSI}$ . The former is obtained by the direct reaction between  $\text{BiCl}_3$  and S, but  $\text{BiI}_3$  and S do not react together; when  $\text{BiBr}_3$  and S are heated together there are indications of the formation of a thio-compound, but none has yet been isolated (*v.* P. M., H. a. R., *C. J.* 39, 21). The thio-compounds are much less stable than the corresponding oxy-compounds; *v.* BISMUTH, OXYHALOID COMPOUNDS OF.

**Bismuth Thiochloride (sulphochloride)  $\text{BiSCl}$ .** Obtained by heating S with  $\text{BiCl}_3$ , or by adding powdered  $\text{Bi}_2\text{S}_3$  to molten  $2\text{NH}_4\text{Cl} \cdot \text{BiCl}_3$ , and washing the product with very dilute  $\text{HCl}$  Aq. Small, metal-like, greyish, needles; easily decomposed into its constituents, *e.g.* by heating in  $\text{CO}_2$  by H, by  $\text{HCl}$  Aq or  $\text{HNO}_3$  Aq, and by alkalis (Schneider, *P.* 93, 464).

**Bismuth Thioiodide (sulphoiodide)  $\text{BiSI}$ ,** is said to be formed, as long needles, by strongly heating I, S, and  $\text{Bi}_2\text{S}_3$ , placed in alternate layers in a large crucible (*P.* 110, 147).

**Bismuthic Acid and Bismuthates** (so called).  $\text{Bi}_2\text{O}_5 \cdot \text{H}_2\text{O}$  is sometimes called bismuthic acid; bodies obtained by dissolving  $\text{Bi}_2\text{O}_5$  in much molten  $\text{KOH}$ , or by saturating with Cl conc.  $\text{KOH}$  Aq holding  $\text{Bi}_2\text{O}_5$  in suspension, have been described as bismuthates. But later experiments have shown that these bodies cannot be isolated although they probably exist in presence of much potash. The acidic functions of  $\text{Bi}_2\text{O}_5 \cdot \text{H}_2\text{O}$  are extremely feeble, *v.* BISMUTH OXIDE under BISMUTH, OXIDES OF, p. 515.

M. M. P. M.

**BISMUTH, ORGANIC DERIVATIVES.****Bismuth mono-methyl compounds.**

**Di-chloride**  $\text{BiMeCl}_2$ . [242°]. Obtained by adding  $\text{BiMe}_3$  to an acetic acid solution of  $\text{BiCl}_3$ . White plates. M. sol. alcohol and acetic acid, insol. ether (Marquardt, *B.* 20, 1520).

**Di-bromide**  $\text{BiMeBr}_2$ . [214°]. Formed by mixing ethereal solutions of  $\text{BiMe}_3$  and  $\text{BiBr}_3$ . Yellow powder. Sl. sol. alcohol, benzene, and acetic acid, insol. ether (M.).

**Di-iodide**  $\text{BiMeI}_2$ . [225°]. Formed by heating  $\text{BiMe}_3$  with methyl iodide at 200° (M.). Glistening red crystals. Sol. alcohol, sl. sol. acetic acid, insol. ether.

**Oxide**  $\text{BiMeO}$ . Formed by adding  $\text{NH}_3$  to an alcoholic solution of the double compound of  $\text{BiMeBr}$  and  $\text{BiBr}_3$ , which is obtained as a yellow crystalline pp. on mixing ethereal solutions of  $\text{BiMe}_3$  (1 mol.) and  $\text{BiBr}_3$  (2 mols.) (Marquardt, *B.* 20, 1522). White powder. Insol. water. Dissolves in  $\text{NaOH}$  and in dilute  $\text{HNO}_3$ . Ignites in the air if gently warmed.

**Bismuth di-methyl compounds.**

**Chloride**  $\text{BiMe}_2\text{Cl}$ . [116°]. Formed by passing chlorine into a solution of  $\text{BiMe}_3$  in petroleum-ether, cooled in a freezing-mixture. White micro-crystalline powder. V. sol. alcohol, insol. ether (Marquardt, *B.* 20, 1519).

**Hydride**  $\text{BiMe}_2(\text{OH})$ . Formed by the action of water upon the double compound of  $\text{BiBr}_3$  and  $\text{BiMe}_2\text{Br}$ , which is ppd. as an oily liquid by mixing ethereal solutions of equal mols. of  $\text{BiBr}_3$  and  $\text{BiMe}_3$ . Crystalline solid. Ignites in the air spontaneously. Dissolves in aqueous  $\text{NaOH}$ . Decomposed by aqueous  $\text{HCl}$  with evolution of  $\text{CH}_4$  (Marquardt, *B.* 20, 1523).

**Bismuth tri-methide**  $\text{BiMe}_3$ . *Tri-methyl-bismuthine*. (110°). S.G. 2.3 at 18°. Obtained by slowly adding an ethereal solution of bismuth bromide (2 mols.) to an ethereal solution of zinc methide (rather more than 3 mols.). Mobile refractive liquid, of unpleasant pungent odour. In the air it fumes and rapidly oxidises, when heated in the air it explodes violently. Volatile with steam, but decomposes on long boiling with water. Dilute  $\text{H}_2\text{SO}_4$  or  $\text{HNO}_3$  have little action upon it, but conc.  $\text{HCl}$  decomposes it with evolution of  $\text{CH}_4$  and production of  $\text{BiCl}_3$ . It does not combine with alkyl haloids or with halogens. The latter replace Me forming  $\text{BiMe}_2\text{Cl}$ , &c. (Marquardt, *B.* 20, 1517).

**Bismuth mono-ethyl compounds.**

**Chloride**  $\text{BiEtCl}$ . Prepared by adding alcoholic  $\text{HgCl}_2$  to alcoholic  $\text{BiEt}_3$  (q.v.).

**Iodide**  $\text{BiEtI}$ . From the chloride and  $\text{KI}$ . Golden, six-sided plates.

**Oxide**  $\text{BiEtO}$ . From the iodide and potash. Yellow amorphous powder, takes fire in air.

**Nitrate**  $\text{BiEt}(\text{NO}_3)_2$ . From the oxide and  $\text{HNO}_3$ . Crystalline tufts.

**Bismuth di-ethyl bromide**  $\text{BiEt}_2\text{Br}$ . Formed by dropping bromine into a cooled solution of  $\text{BiEt}_3$  in petroleum-ether. White powder. V. sol. alcohol, insol. ether. Ignites in the air on warming (Marquardt, *B.* 20, 1520).

**Bismuth tri-ethylide**  $\text{BiEt}_3$ . *Tri-ethyl-bismuthine*. (107°) at 79 mm. S.G. 1.82.

**Preparation.**—1. An alloy of Bi and K is made by strongly heating bismuth (5 pts.) with cream of tartar (4 pts.). This alloy is treated with  $\text{EtI}$  (Breed, *A.* 82, 106).—2. Obtained by slowly

adding an ethereal solution of bismuth bromide (2 mols.) to an ethereal solution of  $\text{ZnEt}_2$  (rather more than 3 mols.) (Marquardt, *B.* 20, 1519).

**Properties.**—Stinking oil. It cannot be distilled at ordinary atmospheric pressure, for on heating to 150° it detonates violently; volatile with steam. Fumes and takes fire in air. V. sol. alcohol, ether, and acetic acid. Its ethereal solution exposed to air deposits  $\text{Bi}_2\text{O}_3\text{H}_2\text{O}$ . Forms unstable compounds with non-metals.  $\text{BiEt}_3\text{S.Bi}_2\text{S}_3$  is a yellow solid, insoluble in water, soluble in yellow ammonium sulphate.  $\text{BiEt}_3$  throws down calomel from alcoholic  $\text{HgCl}_2$ , but when alcoholic  $\text{HgCl}_2$  is added to alcoholic  $\text{BiEt}_3$ , crystals of  $\text{BiEtCl}$  may be got:  $\text{BiEt}_3 + 2\text{HgCl}_2 \rightarrow 2\text{HgEtCl} + \text{BiEtCl}$  (Dönhaupt, *A.* 92, 371).

**Bismuth-tri-phenyl**  $\text{Bi}(\text{C}_6\text{H}_5)_3$ . *Tri-phenyl-bismuthine*. [82°]. S.G. 1.5851 at 20°. Formed by heating bromo-benzene containing some acetic ether with an alloy of sodium and bismuth (10 p.c. Na). Colourless needles or tablets. Sol. hot alcohol, sparingly in cold, v. sol. ether and p-toluene ether. By boiling with conc.  $\text{HCl}$  it is completely decomposed into benzene and bismuth chloride. It combines with  $\text{Cl}_2$  forming the *chloride*  $(\text{C}_6\text{H}_5)_3\text{BiCl}_2$  which crystallises in thick prisms, [110°], sol. hot alcohol, sl. sol. ether and cold alcohol, v. sol. benzene, not decomposed by conc.  $\text{HCl}$ . The *bromide*  $(\text{C}_6\text{H}_5)_3\text{BiBr}_2$  forms long prisms, [119°], v. sol. benzene, sl. sol. alcohol and ether (Michalitz a. Weitz, *B.* 20, 54).

**BITTER ALMOND OIL v. ALMONDS and BENZOYL ALDEHYDE.**

**BIURET**  $(\text{C}_6\text{H}_5\text{N}_3\text{O})_2$ , i.e.  $\text{NH}_2\text{CO.NH.CO.NH}_2$ . *Allophanamide*. Mol. w. 103. [190°]. S. 1.25 at 0°; 1.54 at 15°; 1.54 at 100°.

**Formation.**—1. Urea is heated at 150°–170° until the melted mass becomes pasty and ceases to give off  $\text{NH}_3$ . The product is extracted with hot water (Wiedemann, *P.* 71, 67; Hofmann, *B.* 4, 262).—2. By passing the vapour of cyanic acid into melted urea (Fenck, *A.* 121, 331).—3. Urea is treated with chlorine till the mass becomes pasty (Hoppert a. Dörfl, *Z.* [2] 3, 691; *B.* 4, 175).—4. By the action of  $\text{NH}_3$  on allophanic ether (H. a. D.).—5. By heating 'amido-dicyanic acid' (p. 163) with  $\text{H}_2\text{SO}_4$  (1 pt.) and water (2 pts.) at 60°–70° (Bassmann, *B.* 8, 708).—6. By the action of  $\text{NH}_3$  on tri-bromo-acetyl-urea (Bayer, *A.* 130, 151).—7. By heating urea with  $\text{PCl}_5$  at 100° (West, *B.* 10, 1743).—8. By mixing dilute solutions of urea and potassium cyanate, acidifying with acetic acid, evaporating, adding a little  $\text{H}_2\text{SO}_4$  and extracting with alcohol (Drechsel, *J. pr.* 128, 472).—9. By electrolysis of a solution of  $\text{NH}_3$ , using carbon electrodes (Millot, *Bl.* [2] 46, 214).

**Properties.**—Long needles (containing aq.); or long anhydrous laminae (from alcohol). Split up by heat into  $\text{NH}_3$  and cyanuric acid. Dissolves unchanged in cold conc.  $\text{H}_2\text{SO}_4$ . Its solution is not ppd. by salts of lead or silver or by tannin. A little  $\text{CaSO}_4$  followed by  $\text{KOH}$  gives a deep violet solution.

**Reactions.**—1. At 129° it absorbs  $\text{HCl}$  forming  $\text{B}^+\text{HCl}$  which at 160°–170° in a current of  $\text{HCl}$  gives  $\text{H}_2\text{O}$ ,  $\text{CO}$ , guanidine, cyanuric acid, and urea.—2. Boiling conc.  $\text{HClAq}$  forms  $\text{NH}_3$ , urea, and guanidine.—3. Boiling *baryta-water*

forms  $\text{CO}_2$ ,  $\text{NH}_3$ , and urea.—4. With  $\text{NaClO}$  it evolves  $\frac{1}{2}$  of its nitrogen, with  $\text{NaBrO}$  it evolves  $\frac{3}{4}$  (Fenton, *C. J.* 35, 14).—5.  $\text{HNO}_3$  gives  $\text{CO}_2$  and  $\text{N}_2\text{O}$  in equal volumes (Franchimont, *R. A. C.* 6, 216).—6.  $\text{COCl}_2$  at  $60^\circ$  forms carbonyl-di-biuret ( $\text{C}_4\text{H}_4\text{N}_4\text{O}_4$ ),  $\text{CO}$  (E. Schmidt, *J. pr.* [2] 5, 47); a crystalline powder, v. s. sol. cold water, insol. alcohol and ether. This body is converted by boiling baryta-water into urea and cyanuric acid; and by  $\text{COCl}_2$  at  $140^\circ$  into cyanuric acid;  $\text{H}_2(\text{NO})_2$  gives, in hot dilute solution, a pp. of  $\text{C}_4\text{H}_4\text{N}_4\text{O}_4 \cdot 3\text{H}_2\text{O}$ .

**Salts.**  $\text{H}_2\text{HCl}$ ; decomposed by water.— $\text{AgC}_4\text{H}_4\text{N}_4\text{O}_4$ : ppd. by adding  $\text{AgNO}_3$  (2 mols.) and  $\text{NH}_4\text{Ag}$  to a saturated aqueous solution of biuret (1 mol.); sol.  $\text{HNO}_3$  and  $\text{NH}_4\text{Ag}$  (Bonné a. Goldenberg, *B. J.* 7, 287).—Cyanurate  $\text{H}_2\text{C}_4\text{H}_4\text{N}_4\text{O}_4$ : needles; formed on crystallising biuret from water. It has probably been mistaken for urea cyanurate from which it differs in yielding with baryta water, barium cyanurate and biuret, in giving off 3 atoms of nitrogen as ammonia when heated with barium hydrate (urea cyanurate yields 2 atoms), in giving off 14.8 p.c. nitrogen with sodium hypobromite, (while urea cyanurate gives 11.5 p.c., both results corresponding to 2 atoms nitrogen) (Herzig, *M. Z.* 111).

**Biuret dicyanamide**  $\text{C}_4\text{H}_4\text{N}_4\text{O}_4$  i.e.  $\text{NH}(\text{CO.NH.CN}(\text{NH.NH}))_2$ . From acetyl-urea (2 pts.) and guanidine carbonate (5 pts.) at  $110^\circ$ – $150^\circ$  (Businski, *J. pr.* [2] 27, 157). Amorphous substance, v. sol. acids and fixed alkalis, insol.  $\text{NH}_4\text{Ag}$ . Does not give the biuret reaction with  $\text{CuSO}_4$ .

**BIXIN**  $\text{C}_{20}\text{H}_{28}\text{O}_4$ . [176°]. A colouring matter contained in annatto seeds (*Bixa orellana*) (Preisser, *A.* 52, 382; Girardin, *J. Ph.* [3] 21, 174; Bolley a. Mylius, *Bl.* [2] 3, 230; Stein, *J. pr.* 102, 175).

**Preparation.**—Annatto (1,500 g.) digested at  $80^\circ$  with alcohol (2,500 g. of 80 p.c.) with addition of  $\text{Na}_2\text{CO}_3$  (150 g.); after filtration, the residue is again digested with alcohol (1,500 g. of 60 p.c.). The mixed filtrates are ppd. by adding half their bulk of water and cone.  $\text{Na}_2\text{CO}_3\text{Aq}$ ; the ppd. sodium-bixin is dissolved in alcohol (60 p.c.) and re-ppd. with  $\text{Na}_2\text{CO}_3\text{Aq}$ . The sodium-bixin is then decomposed by  $\text{HCl}$  (Eti, *B.* 11, 861; 7, 416).

**Properties.** Minute red leaflets; insol. water, al. sol. alcohol, benzene,  $\text{CS}_2$ , and acetic acid, v. c. sol. ether. Cone.  $\text{H}_2\text{SO}_4$  forms a bright blue solution, whence water gives a dark green pp. It reduces cold Fehling's solution.

**Reactions.**—1. Distillation with zinc dust gives *n*-xylene, ethyl toluene, and an oil  $\text{C}_{10}\text{H}_{14}$  (270°–280°). Reduced by sodium-amalgam to  $\text{C}_{20}\text{H}_{30}\text{O}_4$ .

**Salts.**  $\text{C}_{20}\text{H}_{28}\text{NaO}_4 \cdot 2\text{aq}$ : lustrous red crystals, v. sol. water, insol. alcohol, and ether.— $\text{C}_{20}\text{H}_{28}\text{NaO}_4 \cdot 2\text{aq}$ : dull red powder.— $\text{C}_{20}\text{H}_{28}\text{K}_2\text{O}_4 \cdot 2\text{aq}$ .  $\text{C}_{20}\text{H}_{28}\text{K}_2\text{O}_4 \cdot 2\text{aq}$ .

**BLEACHING-POWDER** *v.* HYPOCHLORITES, under CHLORINE, OXYACIDS *OF*.

**BLOOD.** In vertebrates, the blood is a somewhat viscous, and to the naked eye homogeneous, red liquid. The blood which leaves the lungs or gills is of a bright scarlet colour, and that in the systemic veins of a purplish blue, which on exposure to the air, or on shak-

ing with oxygen, becomes of the bright arterial scarlet colour. This difference in tint is due to the amount of oxygen present in combination with the red pigment hæmoglobin; in the lungs a loose combination called oxy-hæmoglobin is formed which is scarlet; in the tissues this oxygen is given up, and the blood returning to the heart is of the purplish colour due to hæmoglobin.

**Specific Gravity.** Roy (*Proc. Physiol. Soc.* 1884) has introduced a method for ascertaining the specific gravity of living blood. A drop of blood is introduced into a mixture of glycerin and water of known specific gravity; if the drop tends to rise or sink, it is assumed that it is of lower or higher specific gravity than the liquid in which it is placed. The average specific gravity of human blood thus found was 1.060. Defibrinated human blood has an average specific gravity of 1.055. Pflüger (*Pflüger's Archiv*, i. 75) found the specific gravity of dog's blood to be 1.060; and Gschleiden that of rabbit's blood 1.048.

**Characters.**—Blood is always feebly alkaline in reaction (Kühne, *Virchow's Archiv*, 33, 65; Liebreich, *B. J.* 48; Schäfer, *Journal of Physiology*, 3, 292). Under the microscope the blood is seen not to be a homogeneous red liquid, but to consist of a nearly colourless liquid, the plasma or liquor sanguinis, holding in suspension large numbers of solid bodies, the corpuscles. These corpuscles are of two kinds, the coloured and the colourless.

**Red corpuscles.** These owe their colour to hæmoglobin, and are much more numerous than the white corpuscles. They vary in size and structure in different groups of the vertebrate sub-kingdom. In Mammalia, with the exception of the Camelidae, they are biconcave, circular discs; they have no nucleus except during embryonic life; and they have a tendency to run into rouleaux when the blood is at rest, but if it is disturbed they readily become separated. In the Camel tribe they have an elliptical outline. Their average diameter in mammals is .007–.008 millimetre and about one-fourth of that in thickness; there are very slight variations in different classes of mammals. In birds, reptiles, amphibians, and fishes, the red corpuscles are biconvex, oval discs, with a nucleus; they are largest in the amphibia. C. Schmidt gives the specific gravity of red blood corpuscles as 1.689, Welcker as 1.105.

According to C. Schmidt, 1,000 parts of moist red corpuscles contain—

Water	688 parts.
Solids { Organic	303.88 „
{ Mineral	8.12 „

According to Hoppe Seyler and Jüdel (*Med. Chem. Untersuchungen*, Heft iii. p. 386) 100 parts of dried corpuscles contain—

	Human blood	Dog's blood	Goose's blood
	I.	II.	
Proteids	12.24	5.10	12.55
Hæmoglobin	86.79	94.30	86.50
Lecithin	0.72	0.35	0.59
Cholesterin	0.25	0.25	0.36
			0.48

The nuclei of the red corpuscles consist mainly, according to Lauder Brunton, of nuclein, a substance very akin in its properties to mucin (*Journal of Anat. and Physiology*, 2nd series,

vol. 3, p. 81). The mineral constituents of the red corpuscles have been investigated by C. Schmidt, and the following tables contrast those of the red corpuscles with those of the plasma in man.

1000 parts of moist corpuscles yield—

Mineral matter (exclusive of iron, which is contained in the hæmoglobin . . . . .)	8.120
Chlorine . . . . .	1.686
Sulphuric anhydride . . . . .	0.066
Phosphorus pentoxide . . . . .	1.131
Potassium . . . . .	3.328
Sodium . . . . .	1.052
Calcium phosphate . . . . .	0.114
Magnesium phosphate . . . . .	0.073

1000 parts of plasma yield—

Mineral matter . . . . .	8.550
Chlorine . . . . .	3.640
Sulphuric anhydride . . . . .	0.115
Phosphorus pentoxide . . . . .	0.191
Potassium . . . . .	0.323
Sodium . . . . .	3.341
Calcium phosphate . . . . .	0.311
Magnesium phosphate . . . . .	0.222

The remarkable difference in the distribution of potassium and sodium seen in the above does not, however, hold for most animals as the following table shows (Gauger, *Physiological Chemistry*, p. 122).

	Blood Cells.		
	K.	Na.	Cl.
Man	40.89	9.71	21.00
Dog	6.07	36.17	21.88
Cat	7.85	35.02	27.59
Sheep	14.57	38.07	27.21
Goat	37.41	14.98	31.73

	Liquor Sanguinis.		
	K.	Na.	Cl.
Man	5.19	37.74	40.68
Dog	3.25	39.68	37.31
Cat	5.17	37.61	41.70
Sheep	6.56	38.56	40.89
Goat	8.55	37.89	40.11

Probably the only gaseous constituent of the red blood corpuscles not in a state of chemical combination is carbonic acid.

**Blood tablets.** Besides the red corpuscles, a number of colourless discs of .002-.003 millimetre diameter are also seen; they are also called hæmatoblasts (*Blutplättchen* of Bizzozzer). By some they are supposed to be stages in the development of red corpuscles; by others to take part in the formation of fibrin. Wooldridge considers them to be identical with the proteid he calls fibrinogen A, which can be precipitated from liquor sanguinis by exposure to cold.

**Colourless corpuscles or leucocytes.** These are animal cells, and consist of nucleated masses of protoplasm, more or less granular, and exhibiting during life contractility, the movements so produced being called amoeboid. They are not constant in size, but in man they average about 0.01 millimetre; they are somewhat larger in the lower vertebrate groups. In mammals there is on the average one white or colourless corpuscle to 330 or 350 red ones.

Our knowledge of the chemical constituents of the white corpuscles is meagre; they are lighter than the red ones; the great mass of the protoplasm is undoubtedly proteid in nature; and the nucleus consists mainly of nuclein

(Miescher, *Med. Chem. Untersuch.*, Heft iv., p. 441). By micro-chemical investigation, the presence of glycogen can often be demonstrated by iodine, and of fat granules by osmic acid.

**Coagulation of blood.** Within a few minutes after having been shed, blood passes first into the state of a soft red jelly, which gradually acquires greater consistence; and by the contraction of one of its constituents expresses a fluid, the serum, in which the clot or *crassamentum* ultimately floats.

Coagulation is due to the separation from the blood plasma of a solid proteid substance called fibrin. The clot consists of fibrin entangling the corpuscles. By stirring blood, or whipping it with twigs immediately after it is shed, fibrin free from corpuscles adheres to the twigs as a yellowish stringy mass. Under the microscope, coagulation is seen to consist of the separation of fine filaments from the plasma, which start from or entangle the blood plates, and corpuscles.

Coagulation of the blood is hastened by exposure to a temperature rather above that of the body; by contact with foreign matter, or by agitation; and by dilution with not more than twice its volume of water. Coagulation is hindered or prevented by exposure to a low temperature; by contact with living tissues, or by the addition of large quantities of neutral salts such as sodium chloride, sodium sulphate, or magnesium sulphate. When these precautions are taken, the corpuscles sink, and the plasma can be drawn off; in the last case mixed however with salt solution, the inhibitory influence of which on coagulation can be removed by diluting the mixture with water; fibrin is then formed.

Many theories have been held with regard to the cause of the coagulation of the blood. Nearly up to the end of the last century, the clot was believed to be simply a mass of adherent corpuscles. Hewson, 1772 (r. Hewson's works, edited by Gulliver, *Sydenham Soc.*), was the first to show that it was really due to the separation of some substance from the plasma. Buchanan (*London Medical Gazette*, vol. 18) showed that squeezed blood-clot had the power of hastening the coagulation of the liquor pericardii; and as this power was especially shown by the buffy coat, he supposed that it was due to the white corpuscles; he compared the action of these corpuscles to that of rennet on milk. Denis (*Mémoire sur le sang*, 1859, p. 32), by saturating the liquor sanguinis with sodium chloride, obtained a proteid pp., which after being redissolved in water underwent coagulation. To this precursor of fibrin he gave the name *plasmine*. A. Schmidt (*Archiv f. Anat. u. Physiol.* 1861, 515) separated plasmino into its two constituents, both proteids of the globulin class, to which he gave the names fibrinogen and fibrinoplastin or parafibrin (now called serum globulin). He thought both of these substances were necessary for coagulation, and that they united to form fibrin under the influence of a ferment. This *fibrin-ferment* he prepared from serum, by ppt. it with the serum proteids by means of absolute alcohol; after leaving the pp. some months under alcohol, the proteids were by this means rendered insoluble, while the ferment could be extracted with water.

Gamble (*Journal of Physiology*, 1879) obtained fibrin-ferment by extracting blood-clot with 8 p.c. sodium chloride solution. The extract contained a small quantity of a globulin-like protein, and had very marked power in inducing coagulation. Hammarsten (*Plüger's Archiv*, 14, 211; 17, 413; 18, 38; 19, 563) modified Schmidt's theory by showing that paraglobulin is not necessary for the formation of fibrin, but that fibrinogen is the only true fibrin precursor which under the influence of the fibrin-ferment is converted into fibrin. The presence of paraglobulin, however, hastens coagulation perhaps by its combining with alkaline carbonates which otherwise would impede the action of the ferment; other proteids such as casein, or even salts such as calcium chloride, will, however, take its place.

The source of the fibrin-ferment seems to be the white corpuscles. Rauschenbach has pointed out (*Ueber die Wechselwirkungen zwischen Protoplasma und Blutplasma*, inaug. Diss. Dorpat, 1883) that leucocytes are of two kinds:  $\alpha$  leucocytes which are acted upon and disintegrated by the plasma when the blood is shed, two of the products of such action being paraglobulin and fibrin ferment; and  $\beta$  leucocytes which remain unaltered.

The latest theory of the coagulation of the blood is that of L. C. Wooldridge (*Beiträge zur Physiologie*, Leipzig, 1887, 221). He injects peptone into the circulation of an animal, and kills it by bleeding; the blood remains uncoagulated for many hours, and the corpuscles are removed by centrifugalising; if a substance containing lecithin be then added to the peptone plasma, coagulation occurs. By cooling peptone plasma, a pp. is produced; this consists of little rounded discs similar to blood tablets; this is called fibrinogen  $\alpha$ ; after its removal from the plasma coagulation does not occur; the formation of fibrin is supposed to be due to the lecithin contained in fibrinogen  $\alpha$  combining with fibrinogen  $\beta$  (Hammarsten and Schmidt's fibrinogen).

Human blood yields from 2.2 to 2.8 parts of fibrin per 1,000.

**Serum.** This is the plasma, minus the elements of fibrin. It contains three classes of constituents; proteids, extractives, and salts. The proteids consist of globulin and albumin. Owing to the disintegration of the white corpuscles the globulin is rather more abundant than in the plasma. The following table of Hammarsten's (*Plüger's Archiv*, 1878) represents the percentage of these substances in the serum of some of the commoner mammals:

	Total Solids	Protein	Globulin	Albumin
Bovine	8.597	7.554	1.955	2.177
" Ox	8.363	7.139	1.910	3.529
" Man	9.267	7.619	1.194	4.856
" Rabbit	7.828	6.225	1.788	4.436

The globulin appears to be a single substance; it is coagulated by heat at 75° C.: by fractional heat-coagulation, however, the serum albumin can be differentiated in some animals into two, in some into three proteids (Halliburton, *Journal of Physiology*, 5, 152; Kander, *Arch. f. exp. Path. u. Pharmac.*, 20, 411); in the cold-blooded animals the total quantity of proteids in the

serum is much lower, the serum globulin is always greatly in excess of the serum albumin, and the latter substance is not differentiable into several proteids by fractional heat-coagulation (Halliburton, *Journal of Physiology*, 8, 819).

The extractives of serum are organic substances present in small quantities, which are extracted by various liquids, especially by alcohol or ether. There is about 0.2 p.c. of fats and cholesterol; about 0.8 to 0.12 p.c. of glucose (Pavy, *Croonian Lectures on Diabetes*, London, 1878); urea 0.02 to 0.04 p.c.; and creatine, creatinine, xanthine, hypoxanthine, uric acid, and hippuric acid in still smaller quantities. A yellow pigment is found dissolved in varying quantities in the serum of most animals; Hammarsten (*Mitt. Jahrbuch*, 1878, 129), MacMunn (*Pr.* 31, 231) and others have described this as a biliary pigment; Krukenberg (*Sitzungsber. der Jenaischen Gesellsch. f. Med.*, 1885), and Halliburton (*Journal of Physiology*, 8, 324) have described it as a lipochrome.

The salts of serum amount to 0.7 to 0.9 p.c.

**Gases of the blood.** From the blood as a whole, or from the plasma, coloured corpuscles, or serum, a mixture of carbonic acid, oxygen and nitrogen can be separated. Oxygen is present in much larger quantities than could be held in simple solution in the blood, and is, in fact, held in feeble combination with hemoglobin; only a small part being in solution in the liquor sanguinis. Carbon dioxide is partly in a state of chemical combination, but chiefly in a state of simple solution. It is contained in great part in the liquor sanguinis, but in part also in the corpuscles. The nitrogen is held in simple solution in the liquor sanguinis. Arterial blood of the dog yields for every 100 volumes 58.3 vols. of mixed gases composed of 22.2 vols. of oxygen, 34.3 vols. of carbonic anhydride, and 1.8 vols. of nitrogen. The maximum amount of oxygen observed has been 25.4 vols. (Plüger, *Centralbl. f. d. med. Wissensch.* 1864). In venous blood, the nitrogen is the same as in arterial, the oxygen is less in amount (from 8 to 12 vols. per 100 of blood), and the CO<sub>2</sub> greater (from 40-50 vols. per 100 of blood).

**Lymph.** This is the name applied to that portion of the blood that transudes through the walls of the blood-vessels, and after supplying the tissues with nutritive materials and receiving the products of their combustion returns to the large veins by means of the lymphatic vessels.

Lymph is a transparent liquid, which during digestion is more or less milky, owing to the suspension in it of fatty matters absorbed from the alimentary canal. Its specific gravity varies between 1.012 and 1.022, and its reaction is alkaline.

Under the microscope, the lymph is seen to contain colourless corpuscles. In a time varying from 3 to 20 minutes after it has left the vessels, lymph undergoes coagulation, fibrin being formed. The amount of fibrin which separates is between 0.4 and 0.8 per 1000, being less than that which separates from blood. Lymph is, in fact, simply dilute blood plasma; urea and carbonic acid, however, are rather more abundant in lymph than in blood.

*The Blood in Disease.*

**Anæmia.** The chief change is a reduction in the number of red corpuscles, and the diminution of the amount of hemoglobin they contain. In severe cases there is also a reduction in the solid constituents of the plasma.

**Leucocythæmia.** This is associated with great increase in the number of white corpuscles, which may become nearly as numerous as the red. The blood is poor in hemoglobin, and rich in hypoxanthine and lactic acid (Scherer). Charcot found in the blood, spleen, and liver of patients suffering from leucocythæmia colourless elongated crystals, which he and Vulpian were inclined to consider as proteid in nature; while they were regarded by Salkowski as consisting of a mucin-like substance. Schreiner states that they consist of the phosphate of a base, to the hydrochloride of which he gives the formula  $C_2H_3N.HCl$  (*A.* 194, 68).

**Gout.** In this disease uric acid accumulates in the blood, probably owing to non-elimination by the urine; there is also a large quantity of oxalic acid (Garrod, *Medico-Chirurg. Trans.*, 31, 83; 37, 51).

**Rheumatism.** The fibrin is much increased in amount: the same is, however, true for other inflammatory conditions. There is no excess of uric acid in the blood. Lactic acid is said to be the *materies morbi* by some, but this has never been satisfactorily demonstrated.

**Fevers.**—In various zymotic fevers, and septic diseases, the presence of different forms of bacteria has been described, or in some cases only presumed to exist in the blood. The best known of these are the spirillum of relapsing fever, the bacillus anthracis of splenic fever, and the bacillus malarie of Klebs and Crudele of intermittent fever. Pigment granules of a dark colour are also said to occur in the blood of ague patients. It is probably a derivative of hemoglobin (Marchiafava).

**Diseases of the liver.** In jaundice, bilirubin and in some cases the bile salts also accumulate in the blood; in acute yellow atrophy the blood contains leucine and tyrosine.

**Diabetes mellitus.** In this disease the most marked feature is an increase in the amount of glucose in the blood. The peculiar odour of the breath in diabetics is stated to be due to acetone, and death is often said to result from acetonaemia. It is probable that acetone does not exist free in the blood, but is derived from the splitting up of aceto-acetic ether.

In some cases of diabetes a lipaemia (fat in the blood) condition has been described. But there is no doubt that this may occur without evidence of disease, and also in other diseases than diabetes.

**Bright's disease.** In addition to an anæmic condition, there is an increase in the amount of urea in the blood. The convulsions and coma that are apt to supervene when the elimination of urea is defective have been designated evidences of uramic poisoning. It is probable, however, that in these cases it is not ura itself which is the poison, but probably some substance or substances antecedent to urea. Frerichs' theory that the poison is ammonium carbonate is now given up as untenable.

*The Blood of Invertebrate Animals.*

Our knowledge concerning the blood of invertebrate animals is much less complete than that of the vertebrates. In certain marine animals the circulating fluid is chiefly sea water in which a number of corpuscles are suspended (e.g. echinoderms); in other invertebrates such as crustacea the blood is a highly organised fluid, and rich in proteid constituents, but even in these the amount of saline matters varies with the habitat, being much more abundant in marine than in fresh-water animals. There is never any distinction into blood proper and lymph in invertebrate animals; hence the name *hæmolymp* is sometimes given to their circulating fluid; the term *hydrolymph* is applied in those cases in which the blood is chiefly water, and contains but few organic constituents.

Hæmoglobin is contained in the blood of many invertebrates (Lankester, *Pflüger's Archiv*, 4, 315), chiefly worms, but also in a few crustaceans, insects, molluscs, leeches, and echinoderms. With the exception of four worms and two molluscs, however, it does not occur in special corpuscles as in the blood of vertebrates, but dissolved in the liquor sanguinis, colourless corpuscles only being found in the blood. In other invertebrates this red pigment is replaced by others, which apparently have a similar respiratory function; the most important of these other respiratory proteids are (1) hæmocyannin, a blue pigment occurring in various crustaceans, arachnids, and molluscs (Fredenq, *C. R.* 87, 296). This contains copper as one of its constituent elements; when oxidised it is blue, when reduced it is colourless. (2) Chlorocruorin, a green pigment, closely related to hæmoglobin, found in the blood of certain worms (Lankester, *Journ. of Anat. and Physiol.*, 2, 114). (3) Hæmerythrin, a purplish red pigment found in a few gephyrean worms (Krukenberg, *Verh. phys. Staden*, 1ste Reihe, 3te Abth. p. 82). In all these cases, the pigment is dissolved in the blood plasma, which has thus a respiratory in addition to a nutritive function. In addition to these pigments, others occur which have apparently no respiratory function; thus chlorophyll appears in the blood plasma of many moths and butterflies (Poulton, *Tr.* 38, 269; tetronerythrin, a red lipochrome in the blood plasma of certain crustacea (Halliburton, *Journ. of Physiol.*, 6, 390). Various coloured granules are described in the corpuscles of holothurians and sea urchins (Geddes, v. Gamgee's *Physiol. Chem.*, 134), and the blood of the limpet is described by Krukenberg as being of an orange colour.

The blood of most invertebrates is alkaline in reaction, the only known exception being that of moths and butterflies which is acid (Poulton).

With regard to the coagulation in the blood of invertebrates Halliburton (*Journ. of Physiol.*, 6, 390) was able, in the case of the crustacea, to separate crustacean fibrin, and to show that as in vertebrate blood it was formed from a previously soluble fibrinogen under the influence of a ferment. Crustacean fibrinogen and fibrin differ but little from that of vertebrate blood and the fibrin ferment is identical with that

obtained by Schmidt from vertebrate blood. The coagulation of crustacean blood is also hindered by cold, or admixture with neutral salts. The coagulum formed when the blood of cephalopods is shed is stated by Fredericq to be only a plasma-modium of cells.

[The foregoing article has only discussed blood from a general point of view. The various constituents will be described under their proper headings; the proteins including hæmoglobin and the other blood pigments will be described under the heading *Proteids*.] W. D. H.

#### BLOWPIPE v. ANALYSIS.

**BORIC ACID**  $C_2H_4O_3$ . [100?]. Occurs (to the extent of .2 p.c.), together with quercitannic acid, in black tea (*Thea bohea*) (Rochleder, A. 63, 202). Yellow amorphous resin, v. sol. water and alcohol; ppd. by alcoholic or ammoniacal lead acetate. —  $BaA''$  aq. —  $PbA''$  aq. —  $PbA''PbO$ .

#### BOILING-POINTS v. PHYSICAL METHODS; sec. THERMAL.

**BOLDIN**  $C_{20}H_{32}O_8$ . A glucoside which may be extracted by boiling alcohol from the leaves of *Boldoa fragrans*, in which it occurs to the extent of .3 p.c. It is a syrup, volatile with steam, and decomposed by hot dilute HCl into glucose, MeCl, and an oil  $C_{18}H_{26}O_3$  (?) sol. alcohol, insol. water (Chapoteaut, C. R. 98, 1052). According to Bourgoin a Verne (*Bl.* [2] 18, 481) the leaves of *Boldoa* contain an alkaloid, *boldine*.

#### BOLETUS v. AGARICUS.

**BONE OIL** (Anderson, Tr. E. 16, 4; 20, ii, 247; 21, i, 219; 21, iv, 571; A. 70, 32; 80, 44; 94, 338; 105, 335). The following substances have been isolated from the tar obtained in the dry-distillation of bones:

Chief Constituents.	By-products.
Butyronitrile	Methylaniline
Valeronitrile	Aniline
Hexonitrile	Pyridine
Isohexonitrile	Methyl-pyridine
Deconitrile	Di-methyl-pyridine
Palmitonitrile	Quinoline
Stearonitrile	Phenol
Pyrral	Propionitrile
Methylpyrral	Valeramide
Dimethylpyrral	Toluene
Hydrocarbons:	Ethyl benzene
$C_{12}H_{14}$ (Dihydro-methyl-toluene?)	Naphthalene
$C_{10}H_{12}$ (Dihydro-methyl-cumene?)	
$C_{10}H_{10}$	

Weidel a. Ciamician (B. 13, 65) consider that the nitriles are formed by the action of  $NH_3$  at the high temperature on the fatty acids contained in the bones; the pyridine bases they believe to be formed by the combination of the acrolein (from the glycerin in the fats) with ammonia, methylamine, &c., whilst pyrral and its homologues are products of the decomposition of gelatin.

**BORATES.** Salts of boric acid v. BORON, OXYACIDS OF, p. 528.

**BORAX** v. *Borate of sodium*: under BORON, OXYACIDS OF, p. 529.

**BORIC ACID** v. BORON, OXYACIDS OF, p. 528.

**BORIC ANHYDRIDE** v. BORON, OXIDE OF, p. 527.

**BORIDES.** Compounds of boron with one other more positive element. — Very few of these compounds exist; manganese forms a crystalline boride probably  $Mn_2B_3$ ; platinum easily combines with boron to form PtB (?); and aluminium and boron appear to form a kind of alloy, the proportion of the elements in which varies within very wide limits: two definite borides of Al are also known (v. Iridium, Iron, Manganese, Palladium, Platinum, Aluminium, BORIDES OF).

**BORNEENE.** A mixture of terpenes (q. v.), exuding from *Dryobalanops camphora*, holding borneol in solution (Gerhardt, *Traité*, 3, 628, 641).

**BORNEOL**  $C_{10}H_{18}O$  i.e.  $C_{10}H_{17}OH$ . *Borneo camphor*, *Tetra-hydrate* of (1, 4, 6)-methyl-propyl-phenol (?). Mol. w. 154. [198°] (P.); [207°] (W.) (212°).  $B \propto 76.30$  in a 22.5 p.c. alcoholic solution (Kanonnikoff).

*Occurrence.* — In *Dryobalanops camphora*, being extracted from hollow cavities in the trunk of old trees (Pelouze, A. 40, 326). In the essential oil of valerian (Gerhardt, A. 45, 34; Bruylants, B. 11, 451). To the extent of 4 or 5 p.c. in oil of rosemary (Bruylants, J. 1879, 944; Weber, A. 238, 89).

*Formation.* — 1. By heating camphor with alcoholic KOH (Berthelot, A. Ch. [3] 56, 78). — 2. By the action of sodium on camphor (Baubigny, Z. [2] 3, 71; Haller, C. R. 105, 227).

*Preparation from camphor.* — (Jackson a. Menke, Am. 5, 270; 6, 404; Kachler a. Spitzer, M. 5, 50; B. 15, 16, 2730; Immendorf, B. 17, 1036). Camphor (50g.) is dissolved in alcohol (500 c.c. of 96 p.c.), and sodium (60g.) added slowly. Towards the end of the operation water (50 c.c.) is added (O. Wallach, A. 230, 225).

*Properties.* — Regular crystals; very readily sublimes in plates. Smells like camphor, but more peppery. Has a burning taste. The alcoholic solution is dextrorotatory; artificial borneol has a somewhat higher rotatory power (c. 43°) than the natural borneol ( $[\alpha]_D = 33^\circ$ , (Biot; Kachler). V. sl. sol. water, sl. alcohol and ether. Lighter than water. The rate of etherification of borneol resembles that of primary alcohols (Menschutkin, J. R. 13, 162).

*Reactions.* — 1.  $P_2O_5$  converts it into one or more terpenes (borneene). — 2. Boiling  $HNO_3$  (S.G. 1.42) gives camphor and its oxidation products. — 3. Behaves as an alcohol with regard to  $PCl_5$ . — 4.  $HClO$  converts it into camphor.

*Sodium borneol*  $C_{10}H_{17}ONa$ : six-sided plates (from benzene). Combines with  $CO_2$  forming  $C_{10}H_{17}O(CO_2Na)$  (Kachler a. Spitzer, M. 2, 235).

*Bromide.* — Bromine added to an ethereal solution of borneol forms crystals of a mixture of bromides (?  $C_{10}H_{17}OBr$  and  $(C_{10}H_{17}O)_2Br_2$ ).

*Hydrobromide.* ( $C_{10}H_{17}O$ ).HBr. Crystalline pp. got by passing HBr into a solution of borneol in light petroleum. The compound is unstable and is decomposed both by water and by alcohol.

*Hydriodide.* ( $C_{10}H_{17}O$ ).HI. Prepared similarly.

*Methyl derivative*  $C_{10}H_{19}OMe$ . (194° cor.). From sodium-borneol and MeI (Baubigny, Z. 1868, 299).

**Ethyl derivative**  $C_{10}H_{17}OEt$  (202°) (B.).  
**Formyl derivative**  $C_{10}H_{17}O.CHO$ . (225°-230°). In oil of valerian (Bruylants).

**Acetyl derivative**  $C_{10}H_{17}OAc$ . (221°) (K. a. S.); (227°) (M.). Occurs in oil of valerian (Bruylants, B. 11, 456); and may be formed by the action of  $Ac_2O$  upon borneol (Montgolfier, A. Ch. [5] 14, 50), or of  $AgOAc$  upon bornyl chloride (Kachler a. Spitzer, A. 200, 352). On standing it becomes crystalline [24°]. Fusion with  $NaOH$  gives  $NaOAc$  and borneol.

**Isovaleryl derivative**  $C_{10}H_{17}O(C_4H_9O)$ . (255°-260°).

**Stearyl derivative**  $C_{10}H_{17}O(C_{18}H_{37}O)$ . From borneol and stearic acid at 200° (Berthelot, A. 112, 366). Oil.

**Benzoyl derivative**  $C_{10}H_{17}OBz$ . Oil.

**Levorotatory borneol**  $C_{10}H_{17}OH$ . [35°]. (210°) (Perrot, A. 105, 67).  $[\alpha]_D = -33^\circ$ . Occurs in the alcohol produced by fermentation of the sugar of madder-root (Jeanjean, A. 101, 95). Small regular crystals; sl. sol. water, rotating upon it.  $HNO_3$  forms levorotatory camphor.

**Levorotatory borneol**  $C_{10}H_{17}OH$ . [204°]. S.G. 1.02. From Ngai camphor (Hanbury, J. 1874, 537).

**Levorotatory borneol**  $C_{10}H_{17}OH$ . [201°].  $[\alpha]_D = -37^\circ 21'$  in alcohol of 82 p.e. at 22°. From thymene picrate and boiling  $NaOHAc$  (Lextrait, J. Ph. [5] 13, 265).  $HNO_3$  converts it into a levorotatory camphor [176°] (204°).

**Levorotatory borneol**  $C_{10}H_{17}OH$ . Formed, together with ordinary borneol, by the action of  $Na$  on dextro- or levorotatory camphor (Montgolfier, A. Ch. [5] 14, 21; C. R. 89, 101).

**Inactive borneol**  $C_{10}H_{17}O$ . [199°]. (210°). Among the products of the distillation of colophene (q. v.). Also from its acetyl derivative. **Properties.**—Differs from dextrorotatory borneol only in being inactive. The crystals float on water, but when pressed into a solid cake they sink (unlike camphor). Oxidised by  $HNO_3$  to inactive camphor (Armstrong a. Tilden, C. J. 35, 752). Heated with a large quantity of  $HCl$  it forms  $C_{10}H_{17}HCl$ .

**Acetyl derivative**  $C_{10}H_{17}OAc$ . (215°). From terebene and  $HOAc$  at 100° (Bouchardat a. Lafont, B. [2] 45, 164; C. R. 102, 171).

According to Haller there are two true borneols  $[\alpha]_D = +$  or  $-37^\circ$ , and the others are molecular compounds of these (v. Camphor and Camphol).

**BORNYLAMINE**  $C_{10}H_{17}N$  probably

$C_6H_5 \begin{array}{c} \diagup CH_3 \\ | \\ CH.NH_2 \end{array}$  [160°]. (200°). V.D. 5.5 (for 5.3).  $\alpha_D = -18^\circ 35' 41''$ .

**Formation.**—1. By reduction of camphor-oxim in alcoholic solution by means of sodium. 2. By saponification of its formyl derivative obtained by heating camphor with ammonium formate at 220°-240°.

**Properties.**—Crystalline solid, having an odour resembling both camphor and piperidine. In its physical properties it greatly resembles camphor. Very volatile with steam. Sublimable even at the ordinary temperature. V. sol. alcohol, ether, &c., nearly insol. water. Alkaline reaction to litmus. Takes up  $CO_2$  from the air. **Primary base.** Gives the carbamine reaction. **Levorotatory.** Isomeric with camphylamine.

**Salts.**— $BHCl$ : easily soluble white needles [c. 280°].— $B^+Cl_2H_2PtCl_6$ : golden-yellow plates, v. sol. hot water or alcohol.— $B^+H_2SO_4$ : easily soluble rhombic tables.— $B^+H_2Cl_2HgCl_2$ .

**Formyl derivative**  $C_{10}H_{17}NHCHO$ ; [61°]; colourless glistening plates.

**Acetyl derivative**  $C_{10}H_{17}NHAc$ : [141°] colourless plates.

**Benzoyl derivative**  $C_{10}H_{17}NHbz$ : [131°]; colourless plates; insol. water and cold ligroin (Leuchart a. Bach, B. 20, 104).

**BORNYL BROMIDE**  $C_{10}H_{17}Br$ . [75°]. From borneol and  $HBr$  (Kachler, A. 197, 98).

**BORNYL CARBAMATE**  $C_{10}H_{17}NO_2$  i.e.  $C_{10}H_{17}O.CONH_2$ . [115°]. From sodium-borneol in toluene by the action of cyanogen (Haller, C. R. 93, 1511; 94, 869). Monoclinic needles (containing aq.). Sl. sol. hot water; sublimates partially at 100°. Dextrorotatory. Benzoin aldehyde and  $HCl$  form  $CHPh(NH.CO.O.C_{10}H_{17})_2$  [187°]. Cf. CINZOL.

**BORNYL CARBONATE**  $(C_{10}H_{17})_2CO_3$ . [215°]. Extracted by boiling alcohol from the residue left in the preparation of cyano-borneol from sodium borneol and cyanogen (Haller, C. R. 94, 86). White plates or hexagonal tables, insol. water and alkalis, sl. sol. cold alcohol, sol. ether. May be sublimed. The rotatory power varies with that of the borneol from which it is prepared. Boiling alcoholic  $KOH$  gives  $K_2CO_3$  and borneol.

**BORNYL-CARBONIC ACID**  $C_{10}H_{17}O.CO_2H$ . *Borneol-carboxylic acid.* From sodium-borneol and  $CO_2$  (Baubigny, Z. 1868, 299; Kachler a. Spitzer, M. 2, 236; C. C. 1881, 359).— $NaA$ : crystalline, v. sol. water; slowly decomposed by water with separation of borneol.

**BORNYL CHLORIDE**  $C_{10}H_{17}Cl$ . [157°].

**Formation.**—From borneol (1 pt.) and  $HCl$  (9 pts.) at 100° (Berthelot, A. 112, 366).

**Preparation.**—From  $PCl_5$  (60g.), light petroleum, and borneol (45g. added in portions of 6g.). The product is shaken with water and the petroleum allowed to evaporate in the cold, when bornyl chloride separates (Wallach, A. 230, 231; Kachler, A. 197, 93; B. 11, 460).

**Properties.**—Crystals. V. sol. light petroleum, m. sol. alcohol. Levorotatory.

**Reactions.**—1. Converted into  $HCl$  and camphene  $C_{10}H_{16}$  [52°] (c. 160°), by heating with water (40 pts.) at 95° (Kachler, A. 197, 96); better by warming with aniline (W.). A little borneol is also formed by the action of water on bornyl chloride (Kachler, A. 200, 342; Riban, A. Ch. [5] 6, 382). 2. *Solignol* acting on a solution in benzene forms camphene  $C_{10}H_{16}$  and hydrocamphene  $C_{10}H_{18}$ .

**BORNYL-METHYL-UREA**

$C_{10}H_{17}NH.CO.NHMe$ . (200°). Formed by the action of methyl cyanate upon bornylamine in ethereal solution. Plates. V. sol. ether and hot water (Leuchart a. Bach, B. 20, 108).

**BORNYL OXIDE**  $C_{10}H_{17}O$  i.e.  $(C_{10}H_{17})_2O$  (?). (285°-290°). Occurs in the essential oil of valerian (Bruylants, B. 11, 456). Not attacked by melted  $KOH$ .

**BORNYL PHENYL-CARBAMATE**

$OC \begin{array}{c} \diagup NH.C_6H_5 \\ | \\ OC.C_{10}H_{17} \end{array}$ . *Bornyl-phenyl-urethane.* [133°]. Formed by the action of phenyl cyanate upon borneol. Needles. Sparingly sol. cold

ligroin and alcohol, v. sol. other solvents (Leuchart, *B.* 20, 115).

#### BORNYL-PHENYL-THIOUREA

$C_{10}H_{11}NH_2CS.NH.C_6H_5$ . [170°]. Formed by the action of phenyl mustard-oil upon bornylamine in ethereal solution. Colourless needles. Nearly insol. ligroin (Leuchart n. Bach, *B.* 20, 109).

#### BORNYL-PHENYL-UREA

$C_{10}H_{11}NH.CO.NH.C_6H_5$ . [218°]. Formed by the action of phenyl cyanate upon bornylamine in ethereal solution. Silvery plates or fine needles. Sparingly soluble in ether and cold alcohol, easily in hot alcohol, insoluble in water (Leuchart n. Bach, *B.* 20, 168).

**BORNYL-UREA**  $C_{10}H_{11}NH.CO.NH_2$ . [164°]. Formed by boiling bornylamine hydrochloride with potassium cyanate. Colourless needles. Easily soluble in hot water and alcohol (Leuchart n. Bach, *B.* 20, 169).

**BORNESITE**  $C_2H_2O_2$ . [175°]. [ $\alpha_D^{20}$  -32°]. *Methyl-dimborox*. A volatile substance occurring in the caoutchouc of Borneo. Sublimes at 205°. Sweet taste; does not ferment. After boiling with dilute acids it reduces Fehling's solution. At 120° it is split up by fuming HI into MeI and diborose (Girard, *C. R.* 73, 126).

**BOROFLUORIDES**, v. under BORON, FLUORIDE OR, p. 526.

**BORON**. B. At. w. 10.97. Mol. w. unknown, as V.D. has not been determined. S.G. amorphous not determined, but greater than 1.81 cryst. 2.53-2.68 (Wöhler, *A.* 141, 268; Hampe, *A.* 183, 75). S.H. about .37 at 250°, probably about .5 at 1000° (v. post; p. 525). Crystallises in dimetric forms,  $a:b:c = 1:1:5.762$  (Sella, *P.* 100, 646); but crystals probably contained C and Al (v. post). S.V.S. about 4-1. Combines directly with O and Cl with production of much heat:  $[B_2O_3] = 317,200$ ;  $[B_2Cl_4] = 104,000$  (Troost n. Hautefeuille, *J. Ch. Ph.* [5] 9, 70). Chief lines in emission-spectrum are 2496.2, 2497, 3450.1 (Hartley, *T.* 175, 49).

*Occurrence.*—Not as boron; chiefly as borax and boric acid in volcanic districts, also as borate of Mg with  $MgCl_2$  (*Boracite*), as borate of Ca with Ca silicate (*Dalshite*), &c. Borax, or *tincal*, has been known in commerce for many centuries; boric acid was prepared from borax in 1702 by Homberg; the element was obtained by Gay-Lussac and Thénard in 1808 by deoxidising boric acid by potassium, which metal had been obtained by Davy the year before.

*Formation.*—1. By reduction of  $B_2O_3$  by K (Gay-Lussac n. Thénard, *C. A.* 30, 363).—2. By reduction of  $BF_3.KF$  by K (Berzelius, *P.* 2, 113).—3. By electrolysis of fused  $B_2O_3$  (Davy, *G. A.* 35, 440).—4. By reduction of  $BCl_3$  by H at a red heat (Dumas, *A. Ch.* 31, 376).—5. By fusing dry borax with amorphous P (Dragendoff, *C. C.* 1861, 865).—6. By heating  $BF_3.KF$  or  $BF_3.NaF$  with Mg (Wöhler n. Deville, *A. Ch.* 33, 52, 62; Genthner, *J. Z.* 2, 209).—7. By heating  $B_2O_3$  with Mg and treating the product with  $HClAq$  (Jones, *C. J.* 35, 42).

*Preparation.*—Amorphous. 10 parts fused  $B_2O_3$  in coarse powder are mixed with 6 parts Na in small pieces, the mixture is placed in an iron crucible heated to full redness, 4 to 5 parts of fused NaCl are added, and the crucible is covered. When all action has ceased the

molten mass is stirred with an iron rod, and the contents of the crucible, while still hot, are poured into water containing a little HCl. The NaCl, borax, and  $B_2O_3$  dissolve, and the boron remains. The boron is washed with very dilute  $HClAq$ , then with alcohol, and then with ether; it is then dried at a very gentle heat (Wöhler n. Deville, *A.* 101, 113 a. 347; 105, 67).

**CRYSTALLINE.** Amorphous B is pressed as tightly as possible into a small Hessian crucible, a hole is then made in the mass and a rod of Al (4-6 grams) is placed in the hole: the crucible is covered and placed in another, larger, covered, crucible; the space between is filled with powdered charcoal, and the crucibles are heated to 1500° or 1600° for 1½ to 2 hours; after cooling the mass is treated with dilute  $HClAq$  which dissolves Al, and BN formed in the process (Wöhler n. Deville, *A.* 105, 67). According to Hampe (*A.* 183, 75) the crystals obtained by this process, or by any process said to yield crystalline B, contain Al, and some of them also C; Hampe gives the formula  $AlB_{12}$  to the black crystals, and  $CaAl_2B_{12}$  to the reddish-yellow crystals, obtained by the foregoing method (v. ALUMINIUM, BORIDES OR; and ALUMINIUM, BOROCARBIDE OR).

*Properties.*—Amorphous boron is a greenish-brown, opaque powder; tasteless; odourless; non-conductor of electricity; very infusible, but melts when placed between the poles of a battery of 600 Bunsen-cells. Said to be slightly soluble in water; Reinitzer (*Sitz. W.* 82, 736) supposes that the body which dissolves is a hydride of B (v. BORON, HYDRIDE OR). Insoluble in alcohol or ether. Heated *in vacuo* or in an inactive gas, e.g. H, B becomes darker in colour, heavier, and more compact. Heated in O, burns to  $B_2O_3$ ;  $[B_2O_3] = 317,200$ ; heated in air,  $B_2O_3$  and BN are produced. Oxidised by heating with  $KNO_3$ ,  $K_2CO_3$ , KOH, conc.  $HNO_3Aq$ , or *aquea regia*. Combines directly with many elements e.g. S, Cl, Br, N. The properties assigned by Wöhler n. Deville and others to crystalline B, are, according to Hampe's experiments, the properties of  $AlB_{12}$ ,  $AlB_{10}$ , and  $CaAl_2B_{12}$  (v. ALUMINIUM, BORIDES OR; and BOROCARBIDE OR). The atom of B is trivalent in gaseous molecules (data  $BCl_3$ ,  $BBBr_3$ ,  $BF_3$ ). The atomic weight of B has been determined (i) by finding the V.D. of  $BCl_3$  and  $BBBr_3$  and estimating the Cl and Br respectively in these compounds (Deville n. Dumas, *A. Ch.* [3] 55, 180); (ii) by dehydrating borax (Berzelius, *P.* 2, 129; 8, 19); (iii) by converting dehydrated borax into  $Na_2SO_4$  by action of  $HFAq$  and  $H_2SO_4Aq$  (Berzelius, *P.* 2, 128; also Arfvedson, *P.* 2, 127); (iv) by determining the S. H. of boron (v. *infra*). Boron is a non-metallic element in its chemical reactions; its oxide,  $B_2O_3$ , is an anhydride; boric acid,  $H_3BO_3$ , corresponds in composition to nitrous acid, but thermal data show that boric acid is dibasic; the acids  $H_2BO_3$  and  $H_2B_3O_6$  (and several salts derived from the latter) are also known (v. BORON, OXYACIDS OR).  $B_2O_3$  seems to form compounds with  $P_2O_5$ ,  $SO_3$ , and  $WO_3$ . In some respects B shows analogies with C and Si:—physical properties; existence of acid containing F ( $HBF_4$ ); direct combination with N; existence of many boronungstates; probable existence of a gaseous hydride, &c. In many points B resem-

## BORON

ates N and P:—trivalency of B atom; composition of compounds ( $B_2O_3$ ,  $H_3BO_3$ ,  $BOCl_2$ ,  $BOCl$ , &c.);  $B_2S_3$  not a salt-forming sulphide in reactions with sulphides of very positive metals; existence of a B analogue of tartar emetic, &c. Boron is the first member of Group III (periodic law); the succeeding members of this group are all decidedly metallic; but  $Al_2O_3 \cdot 3H_2O$  dissolves in KOH aq. and forms aluminates (q. v.);  $Al_2S_3$  is also somewhat analogous to  $B_2S_3$ ; the compositions of several B compounds are similar to those of the corresponding compounds of members of Group III, e.g.  $MO_3$ ,  $MX_3$  ( $X=Cl, Br$ ).  $AlCl_3$  and  $BCl_3$  combine directly with  $POCl_3$ . The differences between the chemical functions of B and the other elements of the group to which B belongs seem to be wider than is usual between the first and the following elements of the same group. The boron group comprises the following:

### GROUP III.

Even Series	2.	4.	6.	8.	10.	12.
	B(10)	Al(13)	Ga(31)	In(49)	Tl(81)	
Odd Series	3.	5.	7.	9.	11.	
	A(7)	Ga(69)	Sc(21)	Ti(29)		

These elements are all metallic with the exception of B; in the reactions of  $B_2O_3$  towards certain acids (p. 527) B shows that it may act as a feebly metal-like element. Boric acid is an extremely weak acid; its affinity is very small. The borates are very unstable salts, easily decomposed, even by water, to boric acid and basic oxides. The last member of the group, Tl, shows distinct analogies with the 11th series member of the next group, viz. Pb; B shows distinct analogies with the 2nd series member of the next group, viz. C. B occurs in Series 2, all the succeeding members of this series—C, N, O, F—are very negative and non-metallic; the general character of the series to which it belongs is stamped upon B, and the group-character is but feebly marked. It must, however, be remembered that very few compounds of B, except the borates and their derivatives, have been fully studied.

**Specific heat.** The S.H. of B as determined by Kopp, Regnault, and Mixer a. Dana (J. 126, 362; *Suppl.* 3, 1, 289; J. 1861, 29; A. 169, 388) varied from .225 to .262 for the temperature-interval  $30^\circ$ – $70^\circ$ . In 1873–4 Weber carefully determined the S.H. of crystallised boron (r. P. M. [4] 49, 161, 276); the following table summarises his results:

#### S.H. of crystallised boron.

t.	S.H.	S.H. $\times$ At. w.
$-40^\circ$	.1915	2.11
$+7^\circ$	.2737	3.01
177	.3378	3.72
233	.3663	4.03

The S.H. increases as temperature rises, but the rate of increase per  $1^\circ$  is much smaller at high than at low temperatures. The variations in the rate of increase are almost identical with those observed in the case of carbon (q. v.); assuming that this identity remains at temperatures above  $233^\circ$ , the value which the S.H. of crystallised boron will attain at about  $1000^\circ$  is approximately .5. Weber did not analyse the crystals of boron used; they were prepared by heating boric acid with Al. Accord-

ing to Hampe's investigation crystals thus prepared are a definite compound of B and Al (ante, p. 524).

**Reactions.**—1. Heated in air,  $B_2O_3$  and BN are formed. 2. Heated in oxygen, B burns to  $B_2O_3$ . 3. Heated to redness in N, BN is formed. 4. B combines directly with many elements, e.g. Cl, Br, S, and some metals (r. Bonnier). 5. Water is not decomposed by B at  $100^\circ$  but at a red heat. Steam reacts with B to form boric acid and H. 6. B is oxidised by heating with nitric acid, conc. sulphuric acid, or aqua regia; or by the action of molten nitre, or various oxides of heavy metals. 7. B is also oxidised by heating with potash (H is evolved), or with alkaline carbonates (G is separated, Berzelius, P. 8, 19), or with phosphoric acid (P is separated, Wohler a. Deville, A. Ch. [3] 62, 63). 8. B burns when heated in nitric oxide forming  $B_2O_3$  and BN;  $N_2O$  is without action on B. 9. At a red heat B decomposes sulphuretted hydrogen, hydrogen chloride, and ammonia, forming respectively  $B_2S_3$  and H,  $BCl_3$  and H, BN and H. 10. Many metallic chlorides and sulphides, e.g.  $PbCl_2$ ,  $AgCl$ ,  $PbS$ , are reduced to metal when heated with B. 11. From aqueous solutions of gold chloride B pp. Au. 12. Aqueous solutions of caustic alkalis do not react with B. 13. So-called crystalline boron reacts similarly to amorphous boron, but the reactions occur only at high temperatures; it is oxidised with much difficulty.

**References.** Gay-Lussac a. Thénard, G. A. 30, 363; Davy, G. A. 35, 410; Berzelius, P. 2, 113; Wohler a. Deville, A. 101, 113; 103, 317; 105, 67.

**Boron. Bromide of.**  $BBr_3$ . Mol. w. 250.22. (90.5) (Wöhler a. Deville, A. Ch. [3] 52, 89). S.G. 2.69 (W. a. D. 1 c.). V. D. 127.

**Formation.** 1. By action of Br on  $B_2O_3$  and Cat red heat (Foggiale, C. R. 22, 127). 2. By heating  $B_2O_3$  with  $PBr_3$  (Gustavson, B. 2, 661).

**Preparation.**—Amorphous B is loosely packed into a glass tube, the tube is gently warmed and H is passed through it until every trace of moisture is removed; the H stream is stopped, the corks of the tube are removed for a moment or two, and then the B is gently heated in a stream of dry Br vapour, and the liquid  $BBr_3$  is led into a dry flask surrounded by ice-cold water. The  $BBr_3$  is freed from Br by digestion with Hg, and distillation.

**Properties and Reactions.**—Colourless, strongly fuming, liquid. Reacts with  $H_2O$  to form  $HBr$  aq. and  $H_2BO_3$  aq. Forms a compound with dry  $NH_3$  (r. Also Nickles, C. R. 60, 800; Gautier, C. R. 63, 920).

**Boron. Chloride of.**  $BCl_3$ . Mol. w. 117.08. (18.23) at 760 mm. (Wagnard, Acad. 26, 658). S.G. 1.35 (Wöhler a. Deville, A. Ch. [3] 52, 63). V. D. 58.2. H.F. [ $B, Cl$ ] = 101,000 (Troost a. Hautefeuille, C. R. 70, 185).

**Formation.**—1. By direct combination of B and Cl (Berzelius, P. 2, 147). 2. By the reaction of Cl with  $B_2O_3$  and C at a red heat (Dumas, A. Ch. [2] 31, 436; 33, 376). 3. By the reaction of B with dry  $HCl$ . 4. By reaction between  $HgCl_2$ ,  $PbCl_2$ , or  $AgCl$ , and amorphous B. 5. By heating  $B_2O_3$  with  $PCl_5$  to  $150^\circ$  for some days (Gustavson, B. 3, 426; 4, 975).

**Preparation.**—Amorphous B is heated in H until quite dry, then in dry Cl (details v. Bosow, *Moniteur* or); the exit-end of the tube is connected with a Y tube, the upper part of which is surrounded with a mixture of snow and salt, and the lower limb passes into a dry tube also surrounded by snow and salt.

**Properties.** Colourless, highly refractive, liquid. Very expandable by heat. Fumes in air with decomposition.

**Reactions.**—1. With water forms  $H_2BO_3$  and  $HCl$ aq; [BCl, Aq] 79,200 (Troost & Hauteville, *A. Ch.* [5] 9, 70).—2. Not decomposed by heating with zinc-dust to  $200^\circ$ ; or with sodium below  $150^\circ$ , at  $150^\circ$  B is separated. 3. Heated for some time with superficially oxidised sodium amalgam at  $150^\circ$  B is separated (Gustavson, *B.* 3, 426). 4. Heated with  $P_2O_5$ , the compound  $BCl_2 \cdot POCl_3$  is formed (*v. infra*) (Gustavson, *B.* 4, 975).—5. Heated with sulphur trioxide,  $B_2O_3$  and  $SO_2$  are formed (Gustavson, *l.c.*).—6. With alcohol forms  $B(OEt)_3$  and  $HCl$ .—7. With  $NO$ , reacts to produce  $BCl_2 \cdot NOCl$ ,  $B_2O_3$ , and  $O$  (Gautier, *J. pr.* [2] 8, 854).

**Combinations.**—1.  $BCl_2$  vapour passed into  $POCl_3$  forms crystals of  $BCl_2 \cdot POCl_3$  (Gustavson, *B.* 4, 975). This compound melts at  $73^\circ$  in a closed tube; by sublimation it separates into  $BCl_2$  and  $POCl_3$ ; it is decomposed by water, or moist air, into  $H_2PO_4$ aq,  $H_2BO_3$ aq, and  $HCl$ aq. The same compound is produced by the reaction of  $BCl_2$  with  $P_2O_5$ , and of  $B_2O_3$  with  $POCl_3$  (*l.c.*).—2. With ammonia gas gives  $2BCl_2 \cdot 3NH_3$ , with production of much heat (Berzelius, *P.* 2, 117). 3. The compounds  $BCl_2 \cdot CNCl$  and  $BCl_2 \cdot CNH$  are known (Martius, *A.* 109, 80; Gautier, *C. R.* 63, 920).

**Boron Fluoride of.**  $BF_3$ . Mol. w. 68.27. V. D. 33.7. S. ( $0^\circ$ ) 1013.

**Formation.**—1. By reaction, at white heat, of an intimate mixture of 1 part  $B_2O_3$  with 2 parts  $CaF_2$  free from silica; Gay-Lussac & Thénard (*A. Ch.* 69, 204) prepared  $BF_3$  by this method, in 1810, using vessels of flint, and collecting the gas over Hg.—2. By heating 1 part  $B_2O_3$  with 2 parts  $CaF_2$  and 12 parts conc.  $H_2SO_4$ aq in glass vessels (J. Davy, *T.* 1812, 365); or 1 part  $B_2O_3$ , 1 part  $CaF_2$ , and 20 parts  $H_2SO_4$  (Ferrari, *J. Ph.* 19, 48). Prepared thus, the gas always contains  $SIF_3$  (Berzelius, *P.* 2, 116).

**Preparation.**—100 parts  $KBF_4$  are mixed with 15–20 parts fused and finely powdered  $B_2O_3$ , and the mixture is heated with conc.  $H_2SO_4$ ; the gas is collected over Hg (Schiff, *A. Suppl.* 5, 172).

**Properties.**—Colourless gas, with suffocating odour, condensed to a liquid at  $-110^\circ$  and strong pressure (Faraday, *A.* 56, 152). Acts on organic matter like conc.  $H_2SO_4$ ; incombustible; not decomposed by electric sparks; does not act on glass; is very stable, not decomposed by Fe at red heat.

**Reactions.**—1. with water forms borofluorhydric acid  $HBF_4$ aq (*v. infra*), or fluoboric acid  $HBO_2 \cdot 3H_2O$  (*v. p.* 630), according as the  $BF_3$  is passed into water until the reaction is acid, or until the water is saturated (*v. infra*). [ $BF_3$ aq] = 24,510 (Haunmerl, *C. R.* 90, 312).—2. Conc. sulphuric acid absorbs  $BF_3$  (about 50 vols.), on adding water boric acid is ppt. (J. Davy, *T.* 1812, 365).—3. Alkali, and alkalis

earth, metals react at red heat, forming borofluorides and B (Berzelius, *P.* 2, 138).—4. With alcohol boric acid and ether are formed.

**Combinations.**—With ammonia to form  $BF_3 \cdot NH_3$ , a solid body not decomposed by sublimation; also  $BF_3 \cdot 2NH_3$ , and  $BF_3 \cdot 3NH_3$ , liquids, decomposed by heat, by exposure to air, or by dry  $CO_2$ , giving  $N_2$  and  $BF_3 \cdot NH_3$  (J. Davy, *T.* 1812, 368). According to Kuhlmann (*A.* 39, 320)  $BF_3$  also combines with the oxides of N.

**BOROFLUORHYDRIC ACID, AND BOROFLUORIDES.**  $HBF_4$ ,  $MBF_4$ . (*Hydrofluoboric acid.*) When  $BF_3$  is led into water until the liquid shows a strongly acid reaction, and the liquid is cooled,  $\frac{1}{3}$  of the B of the  $BF_3$  separates as  $H_2B_2O_4$ , and the rest remains in solution in combination with H and F. By neutralising the liquid with  $KOH$ aq, and evaporating, a salt having the composition  $KBF_4$  is obtained. If the acid liquid is evaporated  $HF$  is evolved, and  $H_2B_2O_4 \cdot 6HF$  remains in solution (*v. FLUOBORIC ACID* under Boron, oxyacids or). According to Landolph (*C. R.* 86, 603) the acid  $HBF_4$  may be obtained as a colourless liquid, boiling at  $130^\circ$  with partial decomposition, by the reaction between  $BF_3$  and anethol ( $C_6H_5 \cdot OCH_2 \cdot C_6H_5$ ): the acid reacts with a little water to produce  $HFA$ aq and  $HBO_2$ aq. A solution of  $HBF_4$  is also obtained by dissolving crystallised boric acid in dilute, cooled,  $HFA$ aq.

**BOROFLUORIDES.** These salts have been chiefly studied by Berzelius (*P.* 2, 113). They are obtained by the reactions between (1) metallic oxides or carbonates and  $HBF_4$ aq, (2)  $BF_3$  or  $HBO_2 \cdot 3HFA$ aq and metallic fluorides, (3)  $HFA$ aq and metallic fluorides mixed with  $HBO_2$ ; in the last case half the metal of the fluoride usually forms an oxide. Most borofluorides are crystalline, soluble in water, decomposed by heat to  $BF_3$  and metallic fluoride; heated with conc.  $H_2SO_4$ ,  $BF_3$ ,  $HBF_4$ aq, and metallic sulphate, are produced; fused with alkali carbonates they form a mixture of alkali metal fluoride and alkali borate, this reaction affords the basis of a method for analysing the borofluorides (*v. Marignac, Tr.* 1, 105). Many borofluorides are partially decomposed by water forming so-called basic salts, e.g.  $Ba(BF_4)_2 \cdot 2H_2O$ ,  $Ca(BF_4)_2$ ,  $Pb(BF_4)_2$ ; some—e.g. the Ba or Pb salt—are partially decomposed by alcohol; the aqueous solutions of several—e.g.  $NH_4BF_4$ ,  $Ca(BF_4)_2$ —redden blue litmus.

**Potassium borofluoride**  $KBF_4$ . Obtained as a gelatinous pp. by adding  $HBF_4$ aq to a soluble K salt. Prepared by Stolba (*C. C.* 1872, 395) by heating to boiling 1 part crystallised boric acid, 2 $\frac{1}{2}$  parts powdered  $CaF_2$ , and 5 $\frac{1}{2}$  parts conc.  $H_2SO_4$ , cooling, filtering, p.p.  $KBF_4$  by addition of a soluble K salt, crystallising from hot water—S. (cold) 70.—The salt forms white lustrous six-sided tables; may be crystallised from alcohol or alkali carbonate solutions; melts when heated, and at a high temperature decomposes to  $BF_3$  and KF.

The other borofluorides are  $Al_2(BF_4)_3$ ,  $NH_4BF_4$ ,  $Ba(BF_4)_2 \cdot 2H_2O$ ,  $Ca(BF_4)_2$ ,  $Cu(BF_4)_2$ ,  $Pb(BF_4)_2$ ,  $LiBF_4$ ,  $Mg(BF_4)_2$ ,  $NaBF_4$ ,  $Y_2(BF_4)_3$ ,  $Zn(BF_4)_2$ .

**Boron hydride.** No hydride of B has been obtained free from H; but the experiments of Jones (*C. J.* 35, 41), and of Jones & Taylor

## BORON.

(*C. J. 89*, 112), leave little doubt that a gaseous hydride exists and show that its composition is probably  $BH_3$ .

**Preparation.**—An intimate mixture of 1 part recently heated  $B_2O_3$  and 2 parts Mg dust is placed in a Hessian or iron crucible, the lid is firmly wired down, and the crucible is heated in an ordinary fire; a violent reaction occurs, the crucible is at once removed from the fire; the fused mass—a mixture of B, Mg,  $Mg_2B_3$ ,  $Mg_3N_2$ , and  $MgO$ —is placed in a small flask along with a little  $H_2O$ , and conc.  $HClAq$  is allowed to drop into the flask from a stoppered funnel tube; the gas is collected over water, or is dried by  $CaCl_2$  and collected over  $Hg$ .  $Mg_2B_3$  may also be prepared by direct combination of B and Mg, or by heating Mg in  $BCl_3$  vapour (*J. A. T., C. J. 39*, 214). The gas consists of H mixed with a very small quantity of B hydride.

**Analysis.**—A known volume of pure H was burnt, by hot  $CuO$ , to  $H_2O$ , and the  $H_2O$  was weighed; an equal volume of the gas prepared as above was burnt in the same apparatus, and the  $H_2O$  was weighed; the excess of  $H_2O$  in the second experiment over that in the first gave a measure of the H combined with B as B hydride. The results showed the composition of the hydride to be  $BH_x$ , where  $x > 2$  and is approximately = 3.

**Properties and Reactions.**—Colourless, very disagreeable odour, sparingly soluble in water, solution seems to be unchanged on keeping. Gas burns with bright green flame producing  $H_2O$  and  $B_2O_3$ . Decomposed by passing through a hot tube to B and H. Reacts with  $AgNO_3Aq$  producing small quantity of a black pp. containing B and Ag, and decomposed by  $H_2O$  giving B hydride. Reacts with  $K_2Mn_2O_8Aq$  giving  $MnO_2$  and  $H_2BO_3Aq$ . Combines with  $NH_3$  (conc.  $NH_3Aq$ ) to form a crystalline compound, of unknown composition, decomposed by acids.

**References.**—Older attempts to prepare hydride of boron: Wöhler & Deville (*A. Ch.* [3] 52, 88); Genthier (*J.* 1865, 125); Gustavson (*Z.* 1870, 521) (v. also Reinitzer, *Sitz. W.* 82, 736). Compounds of B with paraffin-radicals are known, e.g.  $BEt_3$  (v. BORON, ORGANIC DERIVATIVES or).

**Boron, Hydroxides of, v. BORON, OXYACIDS or.**

**Boron, Iodide of.** Not known. Wöhler & Deville (*A. Ch.* [3] 52, 90), by the action of I on B at a high temperature, obtained a body which they regarded as an oxyiodide.  $AgI$  does not react with B even at the melting point of Ag.

**Boron, Nitride of.**  $BN$ . Mol. w. unknown, as compound has not been gasified. Obtained in 1842 by Balmann by melting  $B_2O_3$  with  $KCN$  (*P. M.* [3] 21, 170; 22, 467; 23, 71; 24, 191). Composition determined by Wöhler in 1850 (*A.* 74, 70).

**Formation.**—1. By heating B in  $N_2$  or in  $NH_3$ .—2. By heating to whiteness a mixture of 4 parts  $B_2O_3$  and 1 part charcoal powder in  $N_2$ .—3. By heating borax (Wöhler, *l.c.*) or boric acid (*H. Rose, P.* 80, 265), with  $NH_4Cl$  or  $K_2HCy$  (*W. L.c.*) or  $KCN$ , or  $Hg(CN)_2$ , or urea (Darmstadt, *A.* 151, 255).—4. By heating  $2BCl_3 \cdot 3NH_3$  and passing the vapour, along with  $NH_3$ , through a hot tube (Martius, *A.* 103, 80).

5. By heating the compound of  $BCl_3$  with  $NH_3$  Et to  $200^\circ$  (Gustavson, *Z.* [3] 6, 531).

**Preparation.**—A mixture of 1 part dehydrated borax and 3 parts  $NH_4Cl$ —or 7 parts  $B_2O_3$  with 9 parts urea (Darmstadt, *l.c.*)—is strongly heated in a covered Pt crucible, the finely powdered mass is boiled with much water containing a little  $HCl$ , washed with hot water,  $B_2O_3$  is removed by careful treatment with  $HFAq$  (Wöhler, *l.c.*, could not remove all  $B_2O_3$ , thus), and the  $BN$  is washed and dried.

**Properties.**—White, light, amorphous, powder; insoluble in water; infusible; soft (like talc) to the touch; heated in the edge of a flame exhibits greenish-white phosphorescence; very stable and very slightly acted on by most reagents, e.g. by heating in air,  $O$ ,  $I$ ,  $H$ ,  $CO_2$ , or  $CS_2$ , or with conc.  $HClAq$  or  $HNO_3Aq$  or  $KOH Aq$ .

**Reactions.**—1. At a very high temperature reacts with chlorine, to give  $BCl_3$  (Darmstadt, *A.* 151, 255).—2. Heated to redness in steam, or to  $200^\circ$  in a closed tube with water,  $NH_3$  and  $H_2BO_3$  are formed.—3. With molten potash,  $NH_3$  and K borate are produced. 4. With molten potassium carbonate  $KCN$  and  $KBO_2$  are formed, if much  $BN$  is used  $KCN$  is also produced.—5. Oxides of Pb, Cu, or Hg are reduced by heating with  $BN$ , with formation of  $NO$  or  $N_2O$  (Wöhler, *A.* 74, 70).—6. Heated with conc. sulphuric acid, or with conc. hydrochloric acid to  $200^\circ$  in closed tubes,  $NH_3$  and  $H_2BO_3$  are formed.—7. With conc. hydrofluoric acid  $NH_3BF_4$  is formed.—8. Heated in an alcohol-flame fed with oxygen,  $BN$  burns to  $B_2O_3$ .

**Boron, Oxide of.**  $B_2O_3$ . (Boric anhydride.) Mol. w. unknown, as compound has not been gasified. [577] (Carnelley, *C. J.* 33, 278). S.G. 1.75–1.83 (Playfair & Joule, *C. S. Mem.* 3, 57; v. also Ditté, *A. Ch.* [5] 13, 67). S.H. ( $16^\circ$ )  $98^\circ$  2374 (Regnault, *A. Ch.* [3] 1, 129). H. F. [B, O] 317, 200 (Troost & Hautefeuille, *A. Ch.* [5] 9, 70).

**Preparation.**—By heating B in  $O$ , or by strongly heating boric acid (q. v.).

**Properties.**—Semi-transparent, colourless, brittle, inodorous, glass-like, solid; volatilised at a very high temperature (Ebelmen, *A. Ch.* [3] 22, 211); volatilised in steam or alcohol-vapour; non-conductor of electricity (Lapochin & Tichanowitsch, *P. M.* [4] 22, 308; Bowgoin, *C. R.* 67, 798).

**Reactions.**— $B_2O_3$  is a very stable compound; it is not decomposed by heating with powdered charcoal or with P vapour. It is an anhydride, but appears to show a feebly basic character in its reactions with certain acids (*infra* 6–8).

1. Heated with potassium, sodium, or aluminium, metallic oxide and B are formed.—2. Mixed with charcoal and heated in nitrogen, chlorine, bromine, or carbon disulphide,  $BN$ ,  $BCl_3$ ,  $BBr_3$ , or  $BS_3$  is formed.—3. Salts of most acids, e.g. sulphates, nitrates, carbonates, are decomposed by heating with  $B_2O_3$  to a high temperature, with production of borates and volatilisation of the acid (v. Tate, *C. J.* 12, 160).—4. Reacts with most metallic oxides at high temperatures to form borates.—5. With water forms boric acid (q. v.).—6.  $B_2O_3$  is said to react with fuming sulphuric acid to form a compound  $x B_2O_3 \cdot y SO_3 \cdot z H_2O$ ; the values given to x, y, and z by different chemists vary; thus Merz gives the for-

mula  $8B_2O_3 \cdot 2SO_3 \cdot 2H_2O$  (*J. pr.* 99, 161) and Schults-Sellack gives the formula  $B_2O_3 \cdot 2SO_3 \cdot H_2O$  (*B.* 4, 15). This compound is easily decomposed by heat to  $B_2O_3$  and  $SO_3$ .—7.  $B_2O_3$  is said to form a compound with phosphoric anhydride,  $B_2O_3 \cdot P_2O_5$ ; this body is produced by heating together  $H_3BO_3$  and conc.  $H_3PO_4$  (Vogel, *Z.* 1870, 125), and removing excess of the latter by hot water; it is also formed, according to Gustavson (*L.* 3, 426; 4, 975), by heating  $B_2O_3$  with  $PCl_5$  to  $140^\circ$  for 3-4 days, and also by heating  $B_2O_3$  with  $POCl_3$  to  $150^\circ$ – $170^\circ$  for 8 to 10 hours, distilling off the  $POCl_3 \cdot BCl_3$  formed (v. Bovey, *chlorine* or *Combinations*, No. 1) and strongly heating the residual solid.  $B_2O_3 \cdot P_2O_5$  is said to be insoluble in hot water, to be unacted on by acids, dissolved by boiling  $KOH$  (Aq), and to be decomposed by heating with Na, giving Na phosphide, and probably phosphide of B.—8. A compound of  $B_2O_3$  with tungstic anhydride ( $B_2O_3 \cdot 9WO_3 \cdot 2H_2O$ ) is described by Klein (*Bl.* [2] 36, 205), v. TUNGSTOBORATES, under TUNGSTEN.—9.  $B_2O_3$  dissolves in hydrofluoric acid, forming  $B_2O_3 \cdot 6HF \cdot H_2O$  ( $= H_2B_2O_6 \cdot 6HF$ ) (v. Fluoboric Acid, under BONES, OXYGEN, or, p. 530).—10. When a solution of 1 part  $B_2O_3$  and 2 parts  $KHC_2H_3O_2$  in 24 parts  $H_2O$  is evaporated to dryness at  $100^\circ$ , and the residue is treated with alcohol, a white, amorphous solid remains, insoluble in alcohol but very soluble in water. This solid has the composition  $C_2H_5KBO_3$ ; its reactions are similar to those of tartar emetic; probably it is the K salt of an acid  $B_2C_2H_3O_6 \cdot OH$  analogous to the acid  $Sb_2C_2H_3O_6 \cdot OH$  obtained by Clarke & Stallo (*B.* 13, 1787) (v. MEYER, *J. Ph.* 3, 8; Soubeiran, *J. Ph.* 3, 399; 11, 560; 25, 741; 35, 241; Duflos, *S.* 41, 333; Vogel, *J. Ph.* 3, 1; Robiquet, *J. Ph.* [3] 21, 197; Wackenroder, *Ar. Ph.* [2] 58, 4; Wittstein, *R. P.* [3] 6, 1, 177; Duvé, *J.* 1869, 540; Biot, *A. Ch.* [3] 11, 82; v. also under TUNGSTEN).

**Boron, Oxyacids of, and their Salts.** Three definite hydrates of  $B_2O_3$  appear to be known; orthoboric acid  $B_2O_3 \cdot 3H_2O$  ( $= H_3BO_3$ ), metaboric acid  $B_2O_3 \cdot H_2O$  ( $= H_2BO_3$ ), and pyroboric (or tetraboric) acid  $2B_2O_3 \cdot H_2O$  ( $= H_4B_4O_7$ ). Another hydrate  $2B_2O_3 \cdot 3H_2O$  was described by Berzelius (*S.* 23, 161) as obtained by heating  $H_3BO_3$  'considerably over  $100^\circ$ '. Most metallic borates may be regarded as derived from  $H_3BO_3$ ; some—e.g. borax—from  $H_2BO_3$ ; a few are perhaps derived from  $H_4B_4O_7$ , e.g.  $Ca_2B_4O_7$ ; and in addition to these several borates exist which at present must be regarded simply as compounds of  $B_2O_3$  with metallic oxides (v. *infra*). All the boric acids are 'weak' acids, their salts are easily decomposed by reactions with other acids; the affinity of boric acid is extremely small,  $Na_2B_4O_7$  in solution is entirely decomposed by an equivalent of  $H_2SO_4$  (*Th.* 1, 200). Borates of the less positive metals are usually formed only by fusing together  $B_2O_3$  and the metallic oxides. Many of these borates are decomposed by water; some of them are partially converted into carbonates when exposed to the action of moist air; borates even of the very positive metals readily combine with boric acid to form acid salts, but these salts, although containing excess of boric acid, usually turn red litmus blue; even alkali borates are partially decomposed by water. Thomson's thermal inves-

tigation of boric acid proves that the acid obtained by dissolving  $B_2O_3$  in water is dibasic; thus:—

$m[mNaOHAq \cdot B_2O_3 \cdot Aq]$	
1	11,101
2	20,010
3	20,460
6	20,640

The normal Na borate is therefore  $Na_2B_4O_7$ . When boric acid is added to a solution of this salt heat is produced; thus:—

$mNa_2B_4O_7Aq \cdot mB_2O_3Aq$	
1	2,192
4	4,911

Acid salts are therefore probably formed, but the reaction of the solution towards litmus is still alkaline (*Th.* 1, 206).

**Orthoboric Acid.**  $H_3BO_3$  (Boracic Acid; Boric Acid). [ $181^\circ$ – $186^\circ$ ] (Carnelley, *C. J.* 83, 275).

**Occurrence.**—In the waters of many volcanic districts, e.g. in Tuscany; in many mineral springs; in combination with Na as borax—in the waters of certain lakes in S. America, Thibet, Ceylon, &c.; in several minerals, e.g. boracite (borate of Mg), boronatrocalcite (borate of Ca and Na).

**Formation.** 1. By oxidizing B with aqua regia, evaporating, dissolving in water, and recrystallising. 2. By dissolving  $B_2O_3$  in water.

**Preparation.**—3 parts crystallised borax are dissolved in 12 parts boiling water, and (after filtering if necessary) 1 part conc.  $H_2SO_4$  is added; boric acid separates on cooling. The crystals are gently heated, recrystallised from water, dried, fused in a Pt crucible (to remove all  $H_2SO_4$ ), again recrystallised from water, and dried by pressure between filter paper.

**Properties.**—White, semi-transparent laminae; triclinic (Miller, *P.* 23, 558), monoclinic (Goussot, *Sitz.* W. 12, 26). S.G.  $\frac{2}{3}$  1.434 (Stolba, *J. pr.* 90, 457). S. ( $19^\circ$ ) 3.9, ( $25^\circ$ ) 6.72, ( $37.5^\circ$ ) 7.9, ( $50^\circ$ ) 9.84, ( $62.5^\circ$ ) 16.34, ( $75^\circ$ ) 21.15, ( $87.5^\circ$ ) 28.17, ( $100^\circ$ ) 33.67 (Brandes & Firnhaber, *Ar. Ph.* 7, 50; v. also Ditté, *C. R.* 85, 1969). S.G. of  $H_3BO_3$  Aq saturated at  $15^\circ$  = 1.0218 (Stolba, *J. pr.* 90, 457). Heat of solution,  $[H_3BO_3Aq] = -5395$  (*Th.* 3, 196). Soluble in alcohol and several oils (Rose, *P.* 80, 262); soluble in warm conc.  $H_2SO_4$ ,  $HCl$ , or  $HNO_3$  Aq, but most of the boric acid separates on cooling. Aqueous solution turns blue litmus wine-red, and turmeric paper cherry red; alcoholic solution burns with green-edged flame.

**Reactions.**—1. Heated to  $100^\circ$   $H_3BO_3$  is produced (Schaffgotsch, *P.* 107, 427; Bloxam, *C. J.* 12, 177; Merz, *J. pr.* 99, 179); heated to  $140^\circ$  for a long time, or to  $160^\circ$  in a current of dry air,  $H_2B_4O_7$  is formed (Merz, *l.c.*; Ebelmen & Bouquet, *A. Ch.* [3] 17, 63); heated to about  $300^\circ$  the oxide  $B_2O_3$  remains. Berzelius (*S.* 23, 161) said that  $H_2B_4O_7$  ( $= 2B_2O_3 \cdot 3H_2O$ ) is formed by heating  $H_3BO_3$  to a temperature 'considerably above  $100^\circ$ '; Merz (*l.c.*) affirmed the production of  $8B_2O_3 \cdot H_2O$  at  $270^\circ$ .—2. Boiling conc.  $H_2BO_3$  Aq dissolves a few metallic sulphides and oxides (Tissier, *C. R.* 39, 192; 45, 411); decomposes alkali and alkaline earth carbonates (Popp, *A. Suppl.* 8, 10).—3. With alkalis and alkali-carbonates salts of the form

$\text{H}_2\text{B}_4\text{O}_{10}$  or  $\text{H}_2\text{B}_4\text{O}_{10} \cdot 2\text{H}_2\text{O}$  are generally produced; few metallic salts of the form  $\text{M}_2\text{B}_4\text{O}_{10}$  are certainly known; hence  $\text{H}_2\text{B}_4\text{O}_{10}\text{Aq}$  reacts as  $\text{H}_2\text{B}_4\text{O}_{10}\text{Aq}$  (see also BORATES). Etheral salts of  $\text{H}_2\text{B}_4\text{O}_{10}$ , e.g.  $\text{Et}_2\text{B}_4\text{O}_{10}$ ,  $\text{Me}_2\text{B}_4\text{O}_{10}$ , are known, but none of them is directly formed from  $\text{H}_2\text{B}_4\text{O}_{10}$  (p. 530).

**METABORIC ACID,  $\text{H}_2\text{B}_3\text{O}_6$ ; and PYROBORIC OR TETRABORIC ACID,  $\text{H}_2\text{B}_4\text{O}_{10}$ .** Formed by heating  $\text{H}_2\text{BO}_3$  (v. *supra*); glass-like, amorphous solids. Some salts of  $\text{H}_2\text{B}_3\text{O}_6$  are obtained by the reaction between  $\text{H}_2\text{B}_3\text{O}_6\text{Aq}$  and alkalis; salts of  $\text{H}_2\text{B}_4\text{O}_{10}$  are obtained indirectly (v. *infra*).

**BORATES.** No borate is quite insoluble in water; the alkali borates are very soluble. The less soluble borates are easily decomposed by water, the easily soluble salts are also decomposed, but less quickly; an alkali borate, for instance, in conc. aqueous solution slightly reddens litmus, but when much water is added the litmus becomes blue. Solutions of alkali borates absorb  $\text{CO}_2$  and  $\text{H}_2\text{S}$ ; they decompose  $\text{NH}_4$  salts when boiled with them; dilute solutions react with  $\text{H}_2$  and  $\text{Ag}$  salts similarly to alkali solutions. A few borates can be obtained as definite, fairly stable, salts by precipitation from solutions;  $\text{KHB}_4\text{O}_7 \cdot 2\text{H}_2\text{O}$  separates from a solution of  $\text{K}_2\text{CO}_3$  in excess of  $\text{B}_2\text{O}_3\text{Aq}$  to which much  $\text{KOH}\text{Aq}$  has been added;  $\text{MgB}_2\text{O}_4 \cdot 4\text{H}_2\text{O}$  is said to be formed by the reaction between borax solution and  $\text{Mg}(\text{NO}_3)_2\text{Aq}$ . The more definite borates are generally obtained by melting together  $\text{B}_2\text{O}_3$  and basic oxides. As a class the borates very readily undergo change; the composition of very many is therefore extremely doubtful. H. Rose, who investigated many borates, did not attempt to wash his preparations, but pressed them between filter paper till dry, and then determined the quantities of the admixed foreign salts. Most borates seem to belong to the two forms  $\text{M}_2\text{B}_4\text{O}_{10}$  and  $\text{M}_2\text{B}_6\text{O}_{18}$ ; many may be represented as  $\text{M}_2\text{B}_4\text{O}_{10} \cdot n\text{H}_2\text{O}$  and  $\text{M}_2\text{B}_6\text{O}_{18} \cdot n\text{H}_2\text{O}$ ; a few, e.g.  $3\text{M}_2\text{O} \cdot \text{B}_2\text{O}_3$ , may be regarded as derivatives of  $\text{H}_2\text{B}_3\text{O}_6$ . The best-marked borates are the salts of K and Na.

**Potassium borates.**—(1) *Normal metaborate,  $\text{KB}_2\text{O}_4$ .* Monoclinic crystals (biba-2744:122676); by melting, at white heat, 1 part  $\text{B}_2\text{O}_3$  with 1.95 parts  $\text{K}_2\text{CO}_3$ , dissolving in water, evaporating to a syrup out of contact with air, and crystallising (Sehase, *Bestimmung der Krystallgestalten* &c. (Wien, 1855, 31). (2) *Acid metaborate,  $\text{KB}_3\text{O}_6 \cdot \text{H}_2\text{B}_3\text{O}_6 \cdot 4\text{H}_2\text{O}$ .* Regular six-sided prisms; by saturating boiling  $\text{K}_2\text{CO}_3\text{Aq}$  with  $\text{B}_2\text{O}_3\text{Aq}$ , adding  $\text{KOH}\text{Aq}$  to strongly alkaline reaction, evaporating, and crystallising (Laurent, *A. Ch.* 2, 67, 215). Said to sometimes crystallise with  $5\text{H}_2\text{O}$  in rhombic prisms; and to lose  $\text{H}_2\text{O}$  when heated in a closed vessel. (3) *Other acid salts.*  $\text{KB}_3\text{O}_6 \cdot 3\text{H}_2\text{B}_3\text{O}_6 \cdot 6\text{H}_2\text{O}$  obtained like (2), but using less  $\text{KOH}\text{Aq}$ .  $2\text{KB}_3\text{O}_6 \cdot 4\text{H}_2\text{B}_3\text{O}_6 \cdot 5\text{H}_2\text{O}$  (or  $4\text{H}_2\text{O}$ ), by adding  $\text{B}_2\text{O}_3\text{Aq}$  to boiling  $\text{K}_2\text{CO}_3\text{Aq}$  until solution has a slightly acid reaction (Rammelsberg, *P.* 95, 199; Reissig, *A.* 127, 33).

**Sodium borates.**—(1) *Normal metaborate,  $\text{NaB}_2\text{O}_4 \cdot 4\text{H}_2\text{O}$ .* Large monoclinic prisms; by fusing 1 part dry  $\text{Na}_2\text{CO}_3$  with 1.17 parts  $\text{B}_2\text{O}_3$  (or with 3.6 parts crystallised borax), dissolving in water, and crystallising

out of contact with air. Melts at  $571^\circ$  as with  $3\text{H}_2\text{O}$  separates on cooling. Mixed with  $\text{NaF}$  in solution, and crystallised, the  $\text{Na}_2\text{B}_4\text{O}_{10} \cdot 6\text{NaF} \cdot \text{H}_2\text{O}$  separates (v. Fluoboric acid (Hahn, *J.* 1859, 128).—(2) *Acid metaborate,  $\text{NaB}_3\text{O}_6 \cdot 3\text{H}_2\text{B}_3\text{O}_6 \cdot 7\text{H}_2\text{O}$ .* Lustreous, hard, crystal line crust, obtained by boiling solution of: equivs. borax with 1 equiv.  $\text{NH}_4\text{Cl}$  so long as  $\text{NH}_3$  is evolved, and crystallising (Bolley, *J.* 68, 122).  $\text{Na}_2\text{B}_4\text{O}_{10} \cdot 4\text{H}_2\text{O}$ ,  $7\text{H}_2\text{O}$ , small crystals obtained by dissolving in water 1 equiv. borax with 3 equivs.  $\text{H}_2\text{B}_3\text{O}_6$ , and crystallising (Laurent, *C. R.* 29, 5).—(3) *Orthoborate,  $\text{Na}_2\text{B}_4\text{O}_{10}$ .* Said to be formed by fusing  $\text{B}_2\text{O}_3$  with excess of  $\text{NaOH}$  (Bloxam, *C. J.* 14, 143). (4) *Tetra, or pyro, borates.* (a) *Borax.*  $\text{Na}_2\text{B}_4\text{O}_{10} \cdot 10\text{H}_2\text{O}$ , ordinary or prismatic borax;  $\text{Na}_2\text{B}_4\text{O}_{10} \cdot 5\text{H}_2\text{O}$ , octahedral borax. The former occurs native; it is obtained by purifying crude borax, or by fusing 1 part dry  $\text{Na}_2\text{CO}_3$  with 2.34 parts  $\text{H}_2\text{RO}_3$ , dissolving in warm water, and slowly crystallising from a solution of S.G. 1.14–1.15 (B.P. 101°), stopping when the temperature has fallen to  $25^\circ$ – $30^\circ$ . The salt with  $5\text{H}_2\text{O}$  separates from aqueous solutions of ordinary borax of S.G. 1.216 at temperatures between  $56^\circ$  and  $79^\circ$ , or from supersaturated solutions of the same salt protected from dust, or from aqueous solutions of any strength evaporated at  $10^\circ$  to  $12^\circ$  (Gierke, *C. R.* 78, 69). *Ordinary borax* crystallises in large, transparent, colourless, doubly refractive, monoclinic prisms (*acae* 140955:15629,  $\beta$  =  $73^\circ 25'$ ). S.G. 1.69 (Fihol, *A. Ch.* [3] 21, 415). S. (a) 1.28, (20) 1.79, (40) 1.79, (60) 40.4, (80) 76.2, (100) 119.7, (100°) 201.4 (Poggiale, *A. Ch.* [3] 8, 353). S.G. of solution saturated at  $15^\circ$  = 1.0159 (contains 38.491 borax) (Michel & Kraft, *A. Ch.* [3] 41, 471). Insol. in alcohol. Heat disappears during solution; [ $\text{NaB}^{10}\text{O}^{10}\text{H}_4\text{O}$  (Aq)] = 25,860 (Thomson). S.H. (19° 50') = 385 (Kopp, *T.* 155, 71). Refractive indices ( $23^\circ$ ),  $\text{Na}$  light  $\mu$  = 1.4163, for  $\beta$  = 1.4682, for  $\gamma$  = 1.4712 (Abraham, *W. J.* 4, 1). The crystals effloresce in air (according to Sims only when they contain a little carbonate); when heated they melt and give off  $10\text{H}_2\text{O}$ , leaving *burnt borax* ( $\text{Na}_2\text{B}_4\text{O}_{10}$ ), which melts at a red heat to a glass like mass (*effloresced borax*) of S.G. 2.36; exposed to moist air this takes up  $10\text{H}_2\text{O}$ . Solution of borax in water is alkaline to litmus; it dissolves many organic compounds more readily than water, e.g. benzoic acid and gallic acid; some compounds soluble in water dissolve in borax solution, e.g. tartaric acid, various gums, resins, and oils;  $\text{As}_2\text{O}_3$  dissolves easily; silicic acid only very slightly. Molten borax dissolves many metallic oxides and salts forming fusible double salts; hence its use as a flux, and also in analysis. Crystals of *cerussite* were obtained by Eichen (A. *Ch.* 295) by dissolving  $\text{Al}_2\text{O}_3$  in molten borax, and crystals of *rutile* and *tripelite* by dissolving  $\text{TiO}_2$  and  $\text{SiO}_2$ , respectively, in the same solvent (v. Rose, *J. pr.* 101, 228; 108, 208). *Octahedral borax* crystallises in hard, transparent, regular octahedra. S.G. 1.8. Unchanged in dry air, but in moist air changed to prismatic borax. Melts to a glass-like mass.

(b) *Amorphous tetraborate,  $\text{Na}_2\text{B}_4\text{O}_{10} \cdot 4\text{H}_2\text{O}$ .* Obtained according to Schweizer (*A.* 76, 267) by evaporating aqueous borax

solution at 100° and drying the residue at the same temperature for a long time.

(c)  $\text{Na}_2\text{B}_4\text{O}_{10} \cdot 6\text{H}_2\text{O}$  was found by Bechi (*Ann. S. [2]* 17, 129; 19, 120) in an old lagoon; it has not been prepared artificially.

The remaining borates have been chiefly investigated by Berzelius (*S.* 23, 160; *P.* 2, 113; 9, 433; 33, 98; 34, 561); Arfvedson (*Gm.-K.* 6th ed.); Gmelin (*v. Gm.*); H. Rose (*P.* 9, 176; 19, 153; 86, 561; 87, 1, 470, 587; 88, 299, 482; 89, 473; 91, 452); Wöhler (*P.* 24, 525); Rammsberg (*P.* 49, 145); Ebelmen (*J. Ch.* [3] 16, 129; 17, 54; 33, 34); Bouquet (*A. Ch.* [3] 17, 54); Bolley (*A.* 68, 122); Herapath (*P. M.* [3] 84, 575); Laurent (*A. Ch.* [2] 67, 215); Tissier (*C. R.* 39, 192; 45, 411); Bloxam (*C. J.* 12, 177; 14, 113). For an account of various supposed compounds of MO with  $\text{B}_2\text{O}_3$ , v. Ditte (*A. Ch.* [5] 30, 248). The following are the salts which have been chiefly examined; but the composition of many is not settled.

*Alumarium.*— $2\text{Al}_2\text{O}_3 \cdot \text{B}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ ;

$3\text{Al}_2\text{O}_3 \cdot 2\text{B}_2\text{O}_3 \cdot 7\text{H}_2\text{O}$  (H. Rose).— $3\text{Al}_2\text{O}_3 \cdot \text{B}_2\text{O}_3$  (Ebelmen).

*Ammonium.*— $(\text{NH}_4)_2\text{B}_4\text{O}_{10} \cdot \text{H}_2\text{B}_4\text{O}_{10} \cdot 2\text{H}_2\text{O}$  (also  $3\text{H}_2\text{O}$ ) (Arfvedson).— $(\text{NH}_4)_2\text{B}_4\text{O}_{10} \cdot 5\text{H}_2\text{B}_4\text{O}_{10} \cdot 4\text{H}_2\text{O}$  (Bechi, *Ann. S.* [2] 17, 129; 19, 120).

$(\text{NH}_4)_2\text{B}_4\text{O}_{10} \cdot 3\text{H}_2\text{B}_4\text{O}_{10} \cdot 3\text{H}_2\text{O}$  (Gmelin).—

$(\text{NH}_4)_2\text{B}_4\text{O}_{10} \cdot 4\text{H}_2\text{B}_4\text{O}_{10} \cdot 2\text{H}_2\text{O}$  (Rammsberg).

*Barium.*— $\text{BaB}_2\text{O}_6 \cdot 10\text{H}_2\text{O}$  (Berzelius).—

$\text{BaB}_2\text{O}_6 \cdot \text{H}_2\text{O}$  (Rose).— $\text{BaB}_2\text{O}_6 \cdot \text{H}_2\text{B}_4\text{O}_{10} \cdot 4\text{H}_2\text{O}$ ;  $\text{BaB}_2\text{O}_6 \cdot 2\text{H}_2\text{B}_4\text{O}_{10} \cdot 12\text{H}_2\text{O}$ ;  $2\text{BaB}_2\text{O}_6 \cdot \text{H}_2\text{B}_4\text{O}_{10} \cdot 14\text{H}_2\text{O}$  (Laurent).— $\text{Ba}_2(\text{BO}_3)_2$ ;  $2\text{BaO} \cdot \text{B}_2\text{O}_3$ ;  $5\text{BaO} \cdot 2\text{B}_2\text{O}_3$  (Bloxam).— $2\text{BaO} \cdot 3\text{B}_2\text{O}_3$ ;  $\text{Ba}_2\text{O}_3$  (Ditte, *C. R.* 77, 788).

*Cadmium.*— $\text{CdB}_2\text{O}_6$ ;  $2\text{CdB}_2\text{O}_6 \cdot \text{CdO} \cdot \text{H}_2\text{B}_4\text{O}_{10} \cdot 2\text{H}_2\text{O}$  (Rose).

*Calcium.*—

$\text{CaB}_2\text{O}_6 \cdot 2\text{H}_2\text{O}$ ;  $2\text{CaB}_2\text{O}_6 \cdot \text{H}_2\text{B}_4\text{O}_{10} \cdot 4\text{H}_2\text{O}$  (Rose).—

$\text{CaB}_2\text{O}_6 \cdot \text{H}_2\text{B}_4\text{O}_{10}$  (Tünnermann).—

$\text{CaB}_2\text{O}_6 \cdot 3\text{H}_2\text{B}_4\text{O}_{10} \cdot 6\text{H}_2\text{O}$  (Laurent).—

$\text{CaB}_2\text{O}_6$ ;  $3\text{CaO} \cdot 2\text{B}_2\text{O}_3$ ;  $2\text{CaO} \cdot 3\text{B}_2\text{O}_3$ ;

$3\text{CaO} \cdot 3\text{M}_2\text{O} \cdot \text{B}_2\text{O}_3$  (Ditte).

*Cobalt.*— $2\text{CoB}_2\text{O}_6 \cdot \text{CoO} \cdot \text{H}_2\text{B}_4\text{O}_{10} \cdot 3\text{H}_2\text{O}$  (Rose).

*Copper.* Composition very uncertain (v. Tünnermann, Rose, Laurent, Bolley; also LeRoux, *C. R.* 64, 126; Pasteur, *A.* 151, 227; Poussier, *B.* 6, 1138).

*Didymium.*— $\text{DiBO}_3$  (Clève, *Bl.* [2] 43, 361).

*Iron.*— $\text{Fe}(\text{BO}_3)_2 \cdot 3\text{H}_2\text{O}$ ; found in a lagoon-erater (Bechi, *Ann. S.* [2] 17, 129; 19, 120). Basic salts of uncertain composition are formed by the reactions between alkali borates and solutions of ferric salts; borates of Fe and Na seem to be produced by ppg. iron alum with alkali borates (Rose).

*Lead.*— $\text{PbB}_2\text{O}_6 \cdot \text{H}_2\text{O}$ ;  $4\text{PbB}_2\text{O}_6 \cdot \text{H}_2\text{B}_4\text{O}_{10} \cdot 3\text{H}_2\text{O}$ ;  $\text{PbB}_2\text{O}_6 \cdot \text{H}_2\text{B}_4\text{O}_{10} \cdot 3\text{H}_2\text{O}$  (Herapath; v. also Rose).

Double salts:  $\text{PbB}_2\text{O}_6 \cdot \text{Pb}(\text{NO}_3)_2 \cdot \text{H}_2\text{O}$ ;

$\text{PbB}_2\text{O}_6 \cdot \text{PbCl}_2 \cdot \text{H}_2\text{O}$  (Herapath).

*Magnesium.*— $\text{MgB}_2\text{O}_6 \cdot 4\text{H}_2\text{O}$ ;

$\text{MgB}_2\text{O}_6 \cdot 2\text{H}_2\text{B}_4\text{O}_{10} \cdot 6\text{H}_2\text{O}$ ;  $\text{MgB}_2\text{O}_6 \cdot 3\text{H}_2\text{B}_4\text{O}_{10} \cdot 8\text{H}_2\text{O}$ ;

$\text{MgB}_2\text{O}_6 \cdot 5\text{H}_2\text{B}_4\text{O}_{10} \cdot 13\text{H}_2\text{O}$  (Laurent; Rammsberg).

— $\text{MgB}_2\text{O}_6 \cdot 8\text{H}_2\text{O}$  (Wöhler).— $\text{Mg}_3(\text{BO}_3)_2$  (Ebelmen).

Double salts:  $6\text{MgO} \cdot 3\text{X}_2\text{O}_3 \cdot 2\text{B}_2\text{O}_3$  (X = Cr or Fe) (Ebelmen). Ditte describes various compounds of the form  $x\text{MgO} \cdot y\text{CaO} \cdot z\text{B}_2\text{O}_3$ .

*Nickel.*— $\text{NiB}_2\text{O}_6 \cdot 2\text{H}_2\text{O}$  (Rose); also various vague basic salts.

*Rubidium.*— $\text{RbB}_2\text{O}_6 \cdot 6\text{H}_2\text{O}$  (Reissig, *A.* 127, 85).

*Silver.*— $\text{Ag}_2\text{B}_4\text{O}_{10} \cdot \text{H}_2\text{O}$ ;  $8\text{Ag}_2\text{O} \cdot 4\text{B}_2\text{O}_3$  (Rose).

*Strontium.*— $\text{SrB}_2\text{O}_6$ ;  $\text{SrB}_2\text{O}_6$ ;  $3\text{SrO} \cdot 2\text{B}_2\text{O}_3$ ;

$28\text{SrO} \cdot 3\text{B}_2\text{O}_3$  (Ditte).— $8\text{SrB}_2\text{O}_6 \cdot 2\text{H}_2\text{B}_4\text{O}_{10} \cdot 5\text{H}_2\text{O}$ ;

(Rose).— $\text{SrB}_2\text{O}_6 \cdot \text{H}_2\text{B}_4\text{O}_{10} \cdot 3\text{H}_2\text{O}$ ;

$\text{SrB}_2\text{O}_6 \cdot 3\text{H}_2\text{B}_4\text{O}_{10} \cdot 3\text{H}_2\text{O}$  (Laurent).

*Zinc.*—Very vague (v. Rose). Büscher (*A.* 151, 234) describes the double salt

$\text{ZnO} \cdot 4\text{NH}_3 \cdot 2\text{B}_2\text{O}_3 \cdot 6\text{H}_2\text{O}$ .

[? *Samarium borate.*— $\text{SmB}_2\text{O}_6$  (Clève, *Bl.* [2] 43, 170.)]

**FLUOBORIC ACID, AND FLUOBORATES.**  $\text{B}_2\text{O}_3$  appears to react as a feebly basic oxide towards the anhydrides of a few acids, e.g.  $\text{SO}_3$  and  $\text{P}_2\text{O}_5$  (v. Boron, oxide or, *Reactions*, Nos. 6, 7).  $\text{H}_2\text{BO}_3$  dissolves in conc.  $\text{HFAg}$ ; by concentration, and cooling over  $\text{H}_2\text{SO}_4$ , a thick syrup-like liquid is obtained (S.G. 1.584) containing  $\text{H}_2\text{B}_3\text{O}_6$  and  $\text{HF}$  in the ratio  $\text{H}_2\text{B}_3\text{O}_6 : 6\text{HF}$ . This liquid is generally regarded as a definite acid, called *fluoboric acid*. This liquid clears organic matter like  $\text{H}_2\text{SO}_4$ . The same liquid is obtained by saturating water with  $\text{BF}_3$  and distilling (Gay-Lussac u. Thénard, *Recherches physico-chimiques*, 2, 38; Berzelius, *P.* 58, 503; 59, 644). The liquid is decomposed by water into  $\text{HBF}_4$  and  $\text{H}_2\text{B}_3\text{O}_6$  (v. Boron-fluorine compounds, under Boron, fluorine or). If this liquid is neutralised by  $\text{NaOHAg}$  or  $\text{KOHAg}$ , and the solution is evaporated, the salts  $\text{M}_2\text{B}_3\text{O}_6 \cdot 6\text{M} \cdot \text{H}_2\text{O}$  (M = Na or K) are obtained (Berzelius). The same salts are also formed, when M = K by fusing  $\text{KF}$  with  $\text{H}_2\text{BO}_3$ , and when M = Na by crystallising mixed solutions of  $\text{Na}_2\text{B}_4\text{O}_{10}$  and  $\text{NaF}$ . It is very doubtful whether the so-called fluoboric acid is a definite compound or not. According to Basarow (*C. R.* 78, 1698) the liquid prepared as described is decomposed by distillation; at 140°  $\text{BF}_3$  is given off, at 160° to 170° a thick, heavy, fuming liquid (S.G. 1.77) comes over, at 175°–185° a less fuming liquid is produced, and as the temperature rises the distillate becomes lighter and fumes less in air. The heavy distillates are decomposed by water with separation of  $\text{H}_2\text{BO}_3$ . The salts obtained by Berzelius are separated by crystallisation into  $\text{MF}$ , which crystallises out first, and a mixture of  $\text{MF}$  with  $\text{M}_2\text{B}_3\text{O}_6$  (Basarow). Solution of the so-called acid reacts with  $\text{AgNO}_3\text{Ag}$  to give  $\text{Ag}_2\text{B}_3\text{O}_6$  and  $\text{Ag}_2\text{O}$ . Basarow regards fluoboric acid as a mixture of  $\text{H}_2\text{B}_3\text{O}_6$  with  $\text{HBF}_4$  and  $\text{HF}$ . Landolph (*B.* 12, 1583) describes the bodies  $\text{H}_2\text{B}_3\text{O}_6 \cdot 3\text{HF}$  and  $\text{H}_2\text{B}_3\text{O}_6 \cdot 2\text{HF}$ ; the first is obtained in small quantities by the reaction between  $\text{BF}_3$  and  $\text{C}_2\text{H}_5\text{OH}$ , the second is one of the products of the action of  $\text{BF}_3$  on hot anethol. Both bodies are fuming, acid, liquids; they seem to be fairly stable; the first is unchanged by distillation.

**BOROTUNGSTATES.** Many compounds of the form  $x\text{B}_2\text{O}_3 \cdot y\text{WO}_3 \cdot z\text{MO}$  (MO = metal-oxide) have been obtained; the acid  $\text{B}_2\text{O}_3 \cdot 9\text{WO}_3 \cdot 2\text{H}_2\text{O} \cdot 18\text{HAg}$  has been prepared. The principal borotungstates will be described under TUNGSTEN as TUNGSTOBORATES.

**Detection and Estimation of Boric Acid.** Free boric acid is detected by its action on turmeric paper, or by the green colour which it imparts to the flame of burning alcohol; borates do not give these reactions, therefore they must be decomposed by  $\text{H}_2\text{SO}_4\text{Ag}$  before applying the alcohol test, or by  $\text{HClAg}$  before applying the

mercuric paper test. There is no very satisfactory method for estimating boric acid. The most insoluble salt is  $\text{KBF}_4$ ; it is obtained from boric acid or borates by adding excess of  $\text{KOH}$  aq., then evaporating with excess of  $\text{HFAg}$ , dissolving out sulphate, nitrate, &c. of K, by  $\text{KC}_2\text{H}_3\text{O}_2$  aq., washing with alcohol, and drying at  $100^\circ$ . Marignac (*Fr.* 1, 404) evaporates the solution of the borate with excess of  $\text{NH}_4\text{Cl}$  aq. and  $\text{MgCl}_2$  aq., with various precautions, and finally obtains a mixture of  $\text{MgO}$  and  $\text{Mg}$  borate in which he then estimates the amount of  $\text{MeO}$  and so gets the amount of boric acid (v. also Ditte, *C. R.* 80, 190 a, 561). As boric acid interferes with estimation of some other bodies, e.g. phosphoric acid, it is sometimes necessary to remove it; this may be done either by boiling with alcohol and  $\text{H}_2\text{SO}_4$  aq. ( $\text{Et}_2\text{BO}$  goes off), or with  $\text{HF}$  and  $\text{H}_2\text{SO}_4$  aq. ( $\text{BF}_3$  goes off). Rosenbladt (*Fr.* 26, 18) describes a method based on the volatilisation of boric acid by distillation with methylic alcohol; the method gives good results (v. also Giesch, *C. N.* 55, 71).

**Boron, oxychlorides of.** Two are known,  $\text{BOCl}$  and  $\text{BOCl}_2$ ; neither exists as a gas; both are decomposed by heat.  $\text{BOCl}$  is a white gelatinous solid, obtained by heating  $\text{B}_2\text{O}_3$  with  $\text{BCl}_3$  in the ratio  $\text{B}_2\text{O}_3:2\text{BCl}_3$  to 150; at a high temperature it is decomposed to  $\text{BCl}_3$  and  $\text{B}_2\text{O}_3$  (Gustavson, *Z.* 1879, 521).  $\text{BOCl}_2$  is described as a yellowish-green liquid; it was obtained, along with  $\text{BCl}_3$ , by passing  $\text{Cl}$  over a heated mixture of  $\text{B}_2\text{O}_3$  and  $\text{C}$ , removing  $\text{Cl}$  from the gaseous products by  $\text{Cu}$  turnings, condensing, and removing  $\text{BCl}_3$  by evaporation (Coneber, *J. pr.* [2] 18, 329). The conditions under which  $\text{BOCl}_2$  is formed are not definitely known; Coneber obtained the best result when relatively little carbon was used, and a fairly rapid stream of  $\text{Cl}$  was passed through the tube.  $\text{BOCl}_2$  is decomposed by heat into  $\text{BCl}_3$ ,  $\text{B}_2\text{O}_3$ , and  $\text{Cl}_2$ ; and by water to  $\text{H}_2\text{BO}_3$ ,  $\text{HCl}$ , and  $\text{Cl}_2$ . No oxychloride of B is formed by the action of ozone on  $\text{BCl}_3$ , or by passing electric sparks through a mixture of  $\text{BCl}_3$  and  $\text{O}$  (Michaelis a. Becker, *B.* 14, 914).

**Boron, sulphide of.**  $\text{B}_2\text{S}_3$ . Mol. w. unknown, as compound has not been gasified.

**Formation.** -1. By heating B in S vapour to white heat (Berzelius, *P.* 2, 145). -2. By gently heating B in dry  $\text{H}_2\text{S}$  (Wohler a. Deville, *A.* 105, 72).

**Preparation.** Small pellets are made by mixing powdered  $\text{B}_2\text{O}_3$  with soot and oil and heating out of contact with air; these are heated to full redness in a porcelain tube, in a stream of dry  $\text{CS}_2$ ; the tube is connected with two small flasks surrounded by snow and salt. The  $\text{B}_2\text{S}_3$  collects on the surface of the condensed  $\text{CS}_2$ ; it is separated from  $\text{CS}_2$  and dried in an atmosphere of  $\text{H}_2$  (Freymy, *A. Ch.* [3, 38, 322].  $\text{B}_2\text{S}_3$  is a white solid (with a yellowish tinge, Freymy), consisting of groups of small crystals; it smells strongly, and its vapour acts on the eyes; it is rapidly decomposed by moisture to  $\text{B}_2\text{O}_3$  and  $\text{H}_2\text{S}$ ; it may be melted in an atmosphere of  $\text{H}_2$ , and volatilised in a current of  $\text{H}_2\text{S}$ .

M. M. P. 1.

#### BORON, ORGANIC DERIVATIVES OF.

**Boron tri-methide**  $\text{C}_3\text{H}_3\text{B}$  (v.  $\text{BMe}_3$ , V.D. 191 (calc. 1.93). From ethyl borate and  $\text{ZnMe}_2$ , thus:

$2\text{B}(\text{OEt})_3 + 3\text{ZnMe}_2 = 2\text{BMe}_3 + 3\text{Zn}(\text{OEt})_2$  (Frankland, *C. J.* 15, 373). Pungent gas. V. sl. sol. water, v. sol. alcohol and ether. Takes fire in air, burning with a green flame. Not affected by conc.  $\text{H}_2\text{SO}_4$  or by  $\text{HI}$ . Combines with potash forming  $\text{BMe}_3\text{KOH}$ . Combines with ammonia forming  $\text{BMe}_3\text{NH}_3$  [ $56^\circ$ ] ( $110^\circ$ ). Combines also with  $\text{NaOH}$ ,  $\text{CaO}$ , and  $\text{BaO}$ .

**Boron tri-ethide**  $\text{BEt}_3$ . Mol. w. 98. ( $95^\circ$ ). S.G. 73;  $d_4^{20}$  0.66. V.D. 3.40 (calc. 3.40). From  $\text{BCl}_3$  or  $\text{B}(\text{OEt})_3$  and  $\text{ZnEt}_2$  (Frankland, *Fr.* 1862, 167; *Fr.* 25, 165). Pung. oil. Takes fire in air. Slowly decomposed by  $\text{HCl}$ , evolving  $\text{C}_2\text{H}_4$ . Violently attacked by chlorine.

**Combinations.** -1. With ammonia it forms a liquid  $\text{BEt}_3\text{NH}_3$ . -2. By careful oxidation, first in air, then in oxygen, it forms an oxide  $\text{BEt}_3\text{O}_2$  ( $125^\circ$ ). Water decomposes this oxide, forming ethyl-boric acid,  $\text{BEt}(\text{OH})_2$ . Ethyl-boric acid is crystalline, and may be sublimed; its solutions are acid, but it does not form salts. A compound  $\text{BEt}(\text{OEt})\text{B}(\text{OEt})_2$  (v. 112) appears to be formed by the action of  $\text{ZnEt}_2$  (1 mol.) on boric ether; it is decomposed by water into alcohol,  $\text{BEt}(\text{OH})_2$ , and  $\text{B}(\text{OH})_3$ ; and by  $\text{ZnEt}_2$  it is converted into  $\text{BEt}(\text{OEt})_2$  (104), which absorbs oxygen, becoming  $\text{BEt}(\text{OEt})_3$ . Di-ethyl-boric ether,  $\text{BEt}(\text{OEt})_2$ , is caponized by water, and the acid absorbs oxygen, becoming crystalline  $\text{BEt}(\text{OEt})_2(\text{OH})$ , which is converted by water into ethyl-boric acid  $\text{BEt}(\text{OH})_2$ .

**Boron-phenyl-di-chloride**  $\text{C}_6\text{H}_5\text{BCl}_2$ . [about  $0^\circ$ ] ( $175^\circ$ ). Prepared by heating boron trichloride with mercury di-phenyl at  $200^\circ$  (Michaelis a. Becker, *B.* 15, 180). Colourless fuming fluid. By the action of water it gives phenyl-boric acid, and by the action of alcohol, phenyl-boric ether.

**Boron-*p*-tolyl-di-chloride**  $\text{C}_6\text{H}_4(\text{CH}_3)\text{BCl}_2$ . [ $27^\circ$ ]. Colourless crystals. Prepared by heating boron trichloride with mercury di-*p*-tolyl (Michaelis a. Becker, *B.* 15, 185).

**BORO-TARTAR EMETIC** v. BORON, OXIDE OF; *Reactions*, No. 10; also under TARTARATES. **BOROTUNGSTATES.** Compounds of the form  $x\text{B}_2\text{O}_3.y\text{WO}_3.z\text{MO}$  (M = metal), v. TUNGSTOBORATES, under TUNGSTEN.

#### BRASILEIN v. BRAZILEIN.

BRASS v. COPPER, ALLOYS OF.

**BRASSIC ACID**  $\text{C}_{18}\text{H}_{33}\text{O}_2$ . [ $60^\circ$ ]. Prepared by just melting its isomeric, erucic acid, with dilute  $\text{HNO}_3$ , and adding sodium nitrite. Lamine (from alcohol). Combines with bromine. Potash-fusion gives arachic acid.

Salts.  $\text{Na}^+$ : lamine (from alcohol).

**Ethyl ether**  $\text{Et}^+$ : [ $30^\circ$ ]; (above  $360^\circ$ ); distilling plates; obtained by etherifying the acid or by the action of nitrous acid upon ethyl erucate.

**Glycerin-di-brassic ether**  $\text{C}_{18}\text{H}_{33}\text{O}_4$ : (*thraussolin*) [ $65^\circ$ ]; crystal, sl. sol. ether. Formed from glycerin-di-erucic ether by nitrous acid.

**Glycerin-tri-brassic ether**  $\text{C}_{18}\text{H}_{33}\text{O}_6$ : (*tribraussolin*) [ $17^\circ$ ]; after heating [ $36^\circ$ ]; colourless crystalline powder; v. sol. ether, nearly insol. alcohol. Obtained by the action of nitrous acid upon rape-seed oil, and crystallisation of the solid product from ether.

**Amide**  $\text{C}_{18}\text{H}_{33}\text{CONH}_2$ : [ $90^\circ$ ]; colourless

needles; formed by the action of  $\text{NH}_3$  gas upon the anhydride.

**Anilide**  $\text{C}_7\text{H}_7\text{CONHPh}$ : [78°].

**Anhydride**  $(\text{C}_7\text{H}_7\text{CO})_2\text{O}$ : [29°]; glistening tables; v. sol. ether and benzene, insol. alcohol and water; formed by the action of  $\text{PCl}_5$  upon brassylic acid and subsequent addition of alcohol (Reimer a. Will, *B.* 19, 3320; cf. Wesky, *J. pr.* 58, 449; Haussknecht, *A.* 143, 40; Fitz, *B.* 4, 441; Goldschmidt, *Sitz. B.* 74, 304).

**BRASSYLIC ACID**  $\text{C}_{11}\text{H}_{19}\text{O}_4$ . Mol. w. 216. [109°]. Formed, together with its aldehyde and dioxybenholic acid, by the action of fuming  $\text{HNO}_3$  on behenolic acid (Haussknecht, *A.* 113, 45). Crystalline, v. sl. sol. cold water, v. sol. alcohol and ether.

Salts.— $\text{CaA}''$  3aq.— $\text{Ag}_2\text{A}''$ .

**BRASSYLIC ALDEHYDE**  $\text{C}_{11}\text{H}_{19}\text{O}_3$ . The chief product of the action of fuming  $\text{HNO}_3$  on behenolic acid (*p. supra*). Oil, lighter than water, volatile with steam. Sol.  $\text{NaOH}$  aq and reppd. by  $\text{HCl}$ . Oxidised by bromine to brassylic acid.

**BRAZILEIN**  $\text{C}_{18}\text{H}_{12}\text{O}_4\text{H}_2\text{O}$ .

**Formation**.—By the oxidation of brazilin by air in presence of alkalis, or in ethereal solution by  $\text{HNO}_3$  (Reim, *B.* 4, 334; E. Kopp, *B.* 6, 446; Liebermann a. Burg, *B.* 9, 1883; Buchka a. Erck, *B.* 18, 1142).

**Preparation**.—Extract of Brazil-wood is dissolved in hot water and, after cooling,  $\text{NH}_3$  in slight excess is added. The solution is exposed to air, when a pp. is formed which is crystallised from hot dilute acetic acid (Hummel a. A. G. Perkin, *C. J.* 41, 373).

**Properties**.—Minute crystals with grey lustre. Reddish-brown when powdered. Very slightly soluble in cold water, more so in hot water. The solution is yellowish-pink with greenish-orange fluorescence. Alkaline solutions are carmine red, but slowly turn brown in air.

**Reactions**.—1. If hot glacial acetic acid be slowly added to a solution in cold conc.  $\text{H}_2\text{SO}_4$ , minute orange needles of *iso-brazilein sulphate*,  $\text{C}_{18}\text{H}_{12}\text{O}_4\text{SO}_4\text{H}$ , are got. Its alkaline solutions are carmine red quickly turning brown in air. Alcohol turns *iso-brazilein sulphate* scarlet, forming the basic salt  $\text{C}_{18}\text{H}_{12}\text{O}_4 \cdot 2(\text{C}_2\text{H}_5\text{O})_2\text{SO}_4\text{H}$ . 2. Conc.  $\text{HCl}$  at 100° forms  $\text{C}_{18}\text{H}_{12}\text{O}_4\text{Cl}$ . Minute red prisms with violet lustre, called *iso-brazilein chlorhydrin*. Its aqueous solution is orange. 3.  $\text{HBr}$  at 100° forms, similarly,  $\text{C}_{18}\text{H}_{12}\text{O}_4\text{Br}$ . Brazilin resembles hematein (*q. v.*) in these reactions.

**BRAZILIN**  $\text{C}_{18}\text{H}_{12}\text{O}_4$ . Occurs in Brazil-wood (the wood of *Cesalpinia coccinea*) and in Sapan-wood (from *Cesalpinia Sapan*) (Chevreul, *A. Ch.* 66, 226; E. Kopp, *B.* 6, 447; Bolley, *J. pr.* 33, 451).

**Preparation**.—The dark brownish-red crusts deposited during the preparation and storage of commercial extract of Brazil-wood consist of brazilin and its lime compound. The crusts are washed with dilute (5 p.c.)  $\text{HCl}$  and then extracted with very dilute (12 p.c.) alcohol.

**Properties**.—Colourless crystals (containing aq). Sol. water, alcohol, and ether. Turns orange in air. Forms a carmine solution in aqueous  $\text{NaOH}$  in air; this solution is bleached by zinc-dust, but re-oxidised to brazilin by air.

Ascorbic acid may also be turned red by  $\text{NH}$  or haryta when exposed to air.

**Reactions**.—1. Resorcin is among the products of its dry distillation.—2.  $\text{KClO}_3$  and  $\text{HCl}$  give *iso-tri-chloro-glyceric acid* (Benedikt, *A.* 178, 100).

**Salt**.— $\text{PbA}''$  aq: small colourless needles.

**Tri-acetyl-derivative**  $\text{C}_{18}\text{H}_{12}(\text{OAc})_3$ : [106°]; slender colourless needles.

**Tetra-acetyl-derivative**  $\text{C}_{18}\text{H}_{12}(\text{OAc})_4$ : [151°]; glistening needles (Buchka a. Erck, *B.* 18, 1138).

**BREIDIN** v. ARROL-A-BREA.

**BRIMSTONE** v. SULPHUR.

**BRITANNIA METAL** v. TIN, ALLOYS OF.

**BRITISH GUM** v. DEXTRIN.

**BROMAL** v. BROMO-ACETIC ALDEHYDE.

**BROMALIDE**  $\text{C}_2\text{H}_5\text{Br}_2\text{O}$ , i.e.

$\text{CBr}_2\text{CH} < \begin{smallmatrix} \text{CO} \\ \text{O} \end{smallmatrix} > \text{CH.CBr}_2$ . *Tri-bromo-ethyl-*

*ilene tri-bromo-lactate*. [158°]. Formed by heating bromal hydrate with  $\text{H}_2\text{SO}_4$ ; or by warming a mixture of bromal and tri-bromo-lactic acid (Wallach, *A.* 193, 1; Wallach a. Reinecke, *B.* 10, 2128). Monoclinic crystals, insol. water, sol. ether. Decomposed by alcohol.

**BROMANIL** is TETRA-BROMO-QUINONE (*q. v.*).

**BROMATES AND PERBROMATES**.—Salts of bromic and perbromic acids; v. BROMINE, OXYACIDS OF.

**BROMHYDRIC ACID**.  $\text{HBr}$ . (*Hydrobromic acid. Hydrogen bromide*.) Mol. w. 80.75. [−73°]. (−69°) (Faraday, *T.* 1823, 189). V. D. 39.1. S. (−25° to 0° at 760 mm.) about 690; S. (−25° to 0° at 2 mm.) about 345 (Rozeboom, *R. T. C.* 4, 102). H. F. [ $\text{H}, \text{Br}$ ] = 8,440; [ $\text{H}, \text{Br}, \text{Aq}$ ] = 28,376; [ $\text{H}, \text{Br}, \text{Aq}$ ] = 27,837 (*Th.* 2, 29).  $A-1$

$\frac{1}{2}d \times \text{At. wt.} = 20.6$  (Gladstone, *T.* 1870, 9).

$\text{H}$  and  $\text{Br}$  do not combine at ordinary temperatures even in direct sunlight.

**Formation**.—1. By burning  $\text{H}$  charged with  $\text{Br}$  vapour. —2. By passing a mixture of  $\text{H}$  and  $\text{Br}$  over hot  $\text{Pt}$ ; for details of method v. Harding, *B.* 14, 2085. —3. By the action of electric sparks on  $\text{H}$  and  $\text{Br}$ . —4. By the action of  $\text{Br}$  on  $\text{H}_2\text{O}$ , more quickly in presence of oxidisable bodies such as  $\text{P}$ ,  $\text{S}$ ,  $\text{As}$ , or lower oxides of these elements. —5. By passing  $\text{H}_2\text{O}$  and  $\text{Br}$  through a hot tube (Gourson, *C. R.* 13, 1164). —6. By passing  $\text{H}_2\text{S}$  into  $\text{Br}$  and  $\text{H}_2\text{O}$  (Naumann, *B.* 9, 1577). —7. By passing  $\text{HI}$  into  $\text{Br}$  (Hauteville, *C. R.* 61, 705). —8. By the mutual action of  $\text{Na}_2\text{SO}_3$  (Mène, *C. R.* 23, 478), or  $\text{Na}_2\text{S}_2\text{O}_3$  (Gladstone, *J. M.* [3] 35, 343),  $\text{Br}$ , and  $\text{H}_2\text{O}$ :  
 $(\text{Na}_2\text{SO}_3\text{Aq} + \text{H}_2\text{O} + \text{Br}_2 = \text{Na}_2\text{SO}_4\text{Aq} + 2\text{HBrAq})$   
 $(\text{Na}_2\text{S}_2\text{O}_3\text{Aq} + \text{H}_2\text{O} + \text{Br}_2 = \text{Na}_2\text{SO}_4\text{Aq} + \text{S} + 2\text{HBrAq})$ .

9. By leading  $\text{Br}$  into melted paraffin at 185° (Champion a. Pellet, *C. R.* 70, 620).

**Preparation**.—1. When small quantities are required,  $\text{HBr}$  may be prepared by the action of  $\text{P}$  and  $\text{Br}$  on  $\text{H}_2\text{O}$  ( $4\text{H}_2\text{O} + \text{P} + 5\text{Br} \rightarrow \text{H}_3\text{PO}_4 + 6\text{HBr}$ ). A glass tube is bent 3 times at about a right angle; a little  $\text{Br}$  is placed in one bend and a few pieces of  $\text{P}$  in the other; pieces of glass moistened with a very little water are placed in the limb of the tube above the  $\text{P}$ ; a cork with delivery tube is fitted into the open end of the tube above the glass, and the other end of the

tube is closed by a cork. The Br is then very gently warmed; the reaction occurs when the Br vapour reaches the moist P, and the HBr passes off through the delivery tube.—2. When larger quantities of HBr are required it is advisable to use amorphous P. In a flask fitted with a cork carrying an exit tube and a small stoppered separating funnel, is placed 1 part amorphous P mixed with some dry sand, the P is moistened and then covered with a layer of dry sand (Linneemann, A. 161, 198 *note*); the exit tube is connected with a U tube nearly filled with glass beads moistened with conc. HBrAq and pieces of ordinary P (any Br which may come over is converted into HBr in this tube); this is followed by a drying tube containing  $\text{CaCl}_2$  or  $\text{P}_2\text{O}_5$ , and from this a delivery tube passes into a dry cylinder filled with dry Hg standing in a Hg trough. Ten parts of Br are placed in the separating funnel and allowed to drop slowly into the flask; HBr is evolved. Towards the close of the operation the flask is gently warmed. If it is desired to prepare an aqueous solution of HBr, the U tube is fitted with an exit tube passing into the tubulus of a retort placed vertically and arranged so that the beak dips a little way under the surface of water in a bottle; should the flow of HBr slacken, the water rises into the body of the retort but cannot flow back into the generating vessel.—3. By the action of conc.  $\text{H}_3\text{PO}_4$  on KBr; 1 part KBr, 1 part  $\text{H}_3\text{PO}_4$ , and 3 parts  $\text{H}_2\text{O}$  being used (Bertrand, C. R. 82, 96).—4. By decomposing the bromide of an alkaline earth metal by  $\text{H}_2\text{SO}_4$  Aq; Bertrand (*loc. cit.*) employs two parts  $\text{CaBr}_2$ , 2 parts conc.  $\text{H}_2\text{SO}_4$ , and 1 part  $\text{H}_2\text{O}$ . If an alkali bromide is used, the HBr contains much Br and some  $\text{SO}_2$ .—5. An aqueous solution of HBr may be obtained by slowly adding P in small pieces to Br mixed with a considerable quantity of water in a vessel surrounded by ice, then adding a little more Br and then a few pieces of P (repeating if a strong solution is required), and distilling from  $\text{H}_3\text{PO}_4$  Aq (r. Topsöe, B. 3, 400).

**Properties.** HBr is a colourless gas, with pungent, acid, very irritating, odour; excites inflammation when applied to the skin; fumes in moist air; dissolves very largely in water; (p. infra) is absorbed by, and melts, ice; at  $-73^\circ$  liquefies, and then crystallises. Melsens (C. R. 77, 781) obtained liquid HBr by saturating wood charcoal with the gas (15,500 gram-units of heat are produced for every 81 grams HBr absorbed, Favre, A. Ch. [5] 1, 209), placing the charcoal in one end of a closed glass tube bent to an obtuse angle, the other end of which was well cooled, and heating the charcoal in a water bath. An aqueous solution of HBr forms a colourless, strongly acid liquid; the affinity is a very little less than that of  $\text{HCl}$  Aq r. Arrheny.

The conc. solution fumes in, but is not decomposed by exposure to air. S.G. of solution saturated at  $0^\circ$ —1.78; 1 c.c. contains 1.46 grams HBr (=82.02 p.c. HBr by weight) which almost agrees with the composition calculated from the formula  $\text{HBr} \cdot \text{H}_2\text{O}$  (Bineau, A. 41, 237). Roozeboom (R. T. C. 5, 363) has obtained the hydrate  $\text{HBr} \cdot \text{H}_2\text{O}$  as a solid at low temperatures and under a pressure of 3 atmos. If conc. HBrAq is distilled at 760 mm. pressure HBr is evolved, if HBrAq containing less

than 47 p.c. HBr is distilled at 760 mm.  $\text{H}_2\text{O}$  is evolved, in each case the R. P. becomes constant at  $126^\circ$  and the solution contains 47.38—47.86 p.c. HBr; the composition of this liquid is almost exactly that expressed by the formula  $\text{HBr} \cdot 5\text{H}_2\text{O}$  (V. D. = 11.1 agreeing with V. D. calculated for  $\text{HBr} \cdot 5\text{H}_2\text{O}$ ); but it is not probable that the liquid consists of a true hydrate, as the composition varies with the pressure; thus if the pressure is 1,352 mm. the constant R. P. is  $153^\circ$  and the liquid contains 16.3 p.c. HBr (r. Roscoe, A. 116, 263). If dry air is passed through HBrAq at a constant temperature, either HBr or  $\text{H}_2\text{O}$  is removed, and the composition becomes constant; at  $16^\circ$  the liquid finally contains 51.65, and at  $100^\circ$  49.35, p.c. HBr (Roscoe, *loc. cit.*). The S.G. and p.c. composition of HBrAq are given in the following tables (Topsöe, B. 3, 401; Wright, C. N. 23, 212).

Temp.	S.G.	P.c. HBr.	Temp.	S.G.	P.c. HBr.

1.515	49.8

**Reactions.**—1. Not decomposed by heat alone, even at  $706^\circ$  (Hauteville, C. R. 61, 705).—2. Decomposed by heating with many metals, e.g. K, Na, Ba amalgam, Sn, Ac. with formation of metallic bromide and  $\text{H}_2$ .—3. Chlorine forms  $\text{HCl}$  and Br.—4. Conc. nitric or sulphuric acid forms  $\text{Br}$ ,  $\text{H}_2\text{O}$ , and  $\text{NO}_2$  or  $\text{SO}_2$ .—5. Lead or silver oxide forms metallic bromide and  $\text{H}_2\text{O}$  at ordinary temperatures; most of the other metallic oxides decompose HBr in a similar way on warming.—6. Metallic peroxides, and acids containing metals (e.g.  $\text{H}_2\text{SeO}_3$ ), form metallic bromides and Br.—7. Aqueous solution of HBr is decomposed by most metals with formation of metallic bromide and  $\text{H}_2$ ; most metallic oxides dissolve in HBrAq forming bromides. The heat of neutralisation of HBrAq by  $\text{MOH}$  Aq or  $\text{MOH}$  Aq, when M an alkali or alkaline earth metal, is the same as the heat of neutralisation of  $\text{HCl}$  Aq, viz. 13,750; but the quantity of heat produced by the action of HBrAq on the hydrated oxides of Pt and Au, and on  $\text{HgO}$ , is much greater than the quantity of heat produced by the action of  $\text{HCl}$  Aq on the same compounds; the differences are

for $\text{AuO} \cdot \text{H}_2\text{O}$	13,810
" $\text{PtO} \cdot \text{H}_2\text{O}$	11,890
" $\text{PtO} \cdot \text{H}_2\text{O}$	16,300
" $\text{HgO}$	12,290.

The action of HBrAq on these hydrated oxides is very different from the action of the same

sols on the hydrated oxides of K, Ca, Mg, &c.; in the former cases there is little doubt that acids of the form  $H_2HgBr$ ,  $H_2PtBr$ ,  $H_2PtBr$ , and  $H_2AuBr$ , are formed in the solutions (*v. Thomsen, Th. 3, 538*). Many double bromides of Au, Hg, and Pt—*e.g.*  $PtBr \cdot 2KBr$ —are rather to be regarded as alkali salts of these acids than as double salts (*v. Th. 3, 417*; also Gold, MERCURY, PALLADIUM, PLATINUM).—8.  $HBrAq$  is decomposed by bromic acid solution;  $HBrO_2Aq + 5HBrAq = 3H_2OAq + 6BrAq$ .—

9. Conc. sulphuric acid heated with  $HBrAq$  forms  $H_2O$ ,  $SO_2$ , and Br; dilute  $H_2SO_4Aq$  does not decompose  $HBrAq$  at ordinary temperatures.

10. Chlorine sets free Br from  $HBrAq$ .—11.  $HBrAq$  is partly decomposed by potassium permanganate solution in the cold, quickly and completely on heating.—12. By electrolysis of  $HBrAq$ ,  $HBrOAq$  is produced (*Riche, C. R. 46, 548*).—13. Bromine dissolves in  $HBrAq$  forming a dark-coloured liquid.

Combinations.—1. With ammonia and phosphine; Ogier (*C. R. 89, 705*) gives the thermal data,  $[NH_3, HBr] = 45,600$ ;  $[PH_3, HBr] = 23,000$ ; using gaseous constituents and forming solid  $MH_2Br$ . 2. With water probably to form the hydrate  $HBr.H_2O$  (*v. Properties*). The heats of solution and dilution of  $HBr$  have been measured by Thomson (*Th. 3, 13 and 72*); the results indicate the existence in the solution of the hydrate  $HBr.H_2O$ , but do not suggest the formation of any other definite hydrate on dilution. The heat of dilution appears to be a continuous hyperbolic function of the quantity of water added, provided the composition of the acid to start with is  $HBr.H_2O$ ; the results cannot, however, be expressed by quite so simple a formula, involving a single constant, as is applicable in the case of chlorhydric acid (*v. r.*). It is quite possible that the reactions of  $HBrAq$  are the reactions of the acid  $HBr.H_2O$  (*v. H.Br.OH*), and that  $HBr$  itself is not an acid (*v. Presidential Address to Section B. by P. of Armstrong, R. A. Meeting, 1885*). Berthelot (*Bl. [2] 19, 385; C. R. 61, 114; 66, 712*) thinks that  $HBrAq$  contains a number of hydrates, some partially dissociated, and also the compound  $HBr$  (*v. Chlorhydric acid*). Roozeboom (*R. T. C. 4, 108, 331; 5, 351, 363*; also Van't Hoff, *ibid. 4, 411*) has determined the relations between vapour-pressure and temperature of solutions of hydrated  $HBr$ . M. M. P. M.

**BROMIC ACID**  $HBrO_3$ , *v. BROMINE, oxy-*

**BROMIDES.** Binary compounds of Br with more positive elements *i.e.* with any element except F, Cl, or O. Br forms binary compounds with most of the elements. The greater number may be produced by direct combination. The formation of metallic bromides is usually accompanied with production of much heat; thus,  $[K, Br] = 190,620$ ;  $[Ca, Br] = 140,850$ ;  $[Zn, Br] = 75,930$ ;  $[Hg, Br] = 50,550$ ;  $[Au, Br] = 8,850$ . (Liquid Br was used.) Some metallic bromides are formed by the action of Br on the oxides; *e.g.*  $AgBr$  by Br on  $Ag_2O$ . Alkalis and alkaline earths in aqueous solutions are decomposed by Br, giving bromides and bromates; certain metallic salts, in aqueous solutions, form bromides and peroxides; *e.g.* salts of Mn, Ni, Co, and Pb. Metallic iodides

are decomposed wholly or in part by Br, giving metallic bromides and free I. Many metallic chlorides are partly decomposed when heated in closed tubes to about  $300^\circ$  with equivalent quantities of Br; after a time equilibrium is established in the system consisting of chloride, bromide, Cl, and Br; this equilibrium is not overthrown by increasing the mass of Br, the temperature, or the time (*Potilitzin, B. 14, 1044; 15, 918; 16, 3051*). Metallic bromides are usually formed by the action of  $HBrAq$  on the oxides (comp. BROMINE ACID; *Reactions*, No. 7). Most metallic bromides are white; they are generally isomorphous with the corresponding chlorides; most of them are not decomposed by heat alone, but some, *e.g.* those of Au and Pt, give up all their Br when heated. Some metallic bromides are decomposed by  $H_2O$ , *e.g.* those of Bi and Sb; others are decomposed when their aqueous solutions are evaporated, *e.g.*  $AlBr_3$ ; most are decomposed by heating in air in presence of steam. Metallic bromides are decomposed by certain peroxides and oxidising agents, *e.g.*  $MnO_2$ ,  $K_2MnO_4Aq$ ,  $K_2Cr_2O_7Aq$ ,  $HNO_3Aq$ , with separation of Br; conc.  $H_2SO_4Aq$  sets free a little  $HBr$ , but decomposes most of the bromides to sulphate and Br with simultaneous formation of  $SO_2$ ;  $HCl$  and  $HClAq$  form  $HBr$  and metallic chloride. When a metallic bromide is heated with solid  $K_2Cr_2O_7$  and conc.  $H_2SO_4$ , free Br is obtained (distinction from chlorides). Aqueous solutions of alkali bromides dissolve large quantities of Br, probably with formation of perbromides in solution; Berthelot (*C. R. 91, 195 and 706*) gives the numbers (using gaseous Br)  $[KBrAq, Br] = 11,500$ . Aqueous solutions of alkali, alkaline earth, and magnesium bromides partly decompose  $AgCl$  when the salts are shaken together for a few minutes at the ordinary temperature; the percentage of  $AgBr$  formed varies from 95 when  $LiBrAq$  is used, to 81% when  $CaBr_2Aq$  is employed (*Potilitzin, B. 18, 1522*). The binary compounds of Br with the non-metals are fairly stable bodies; they are usually produced by direct combination. Bromides of B, P, C, and Si are stable as gases. Br forms definite, stable, compounds only with the more metallic and positive members of the oxygen group of elements; bromides of Te are gasifiable,  $Se_2Br_2$  is fairly stable, but is decomposed by heat,  $S_2Br_2$  is a feebly-marked body, and no oxide of Br is known. Bromide of iodine is a fairly well marked compound,  $[I, Br] = 2,500$  (*Berthelot, C. R. 90, 841*; using liquid Br and solid I). Bromine chloride is very easily decomposed, and no compound of Br and F is definitely known. If N bromide exists it is extremely unstable (*v. also HALOGEN ELEMENTS, binary compounds of*; for the individual bromides *v. the articles on the various elements*).

M. M. P. M.

**BROMIDES, ORGANIC** *v. BROMINE, organic compounds of*.

**BROMINE.** Br. At. w. 79.75. Mol. w. 159.50. [ $-21.5^\circ$ ] (*Baumhauer, Z. 4, 927*), [ $-7.2^\circ$ ] (*Phil pp. B. 12, 1421*; according to Philipp, the lower M.P. was due to presence of Cl). [ $-7.05^\circ$ ] (*Ramsay & Young, C. J. 49, 453*); ( $63^\circ$ ) (*Pierre, A. Ch. [3] 20, 5*); ( $59.27^\circ$ ) (*Thorpe, C. J. 37, 172*); ( $58.7^\circ$ ) (*Ramsay & Young, l.c.*). S.G.  $\frac{4}{4}$  3.1872 (*Pierre, l.c.*);  $\frac{4}{4}$  3.18928 (*Thorpe,*

sparingly in water (v. supra); solutions of  $x$  parts Br by weight in 1,000 parts  $H_2O$  have following S.G. (Stessor, J. 1858, 100):—

$x$ .	S.G.	$x$ .	S.G.	$x$ .	S.G.
10.7	1.009	12.3	1.0122	20.9	1.018
11.7	1.0093	18.7	1.0140	31.31.7	1.0236
12.0	1.0099	19.5	1.0158		

Solution in water is attended with production of heat  $[Br, Aq] = 1080$  (77.2, 25); solution is pale orange-yellow. Dissolves more readily in alcohol, and in all proportions in ether,  $CS_2$ , and  $CHCl_3$ ; solution is accompanied by chemical change; soluble also in conc. aqueous solutions of  $KBr$  and many other metallic bromides, frequently with formation of perbromides; also in conc.  $HClAq$  and  $HBrAq$ , and in liquid  $SO_2$  (Hestini, Z. 1868, 718). Br is absorbed by wood charcoal with considerable rise of temperature (Melsens, C. R. 77, 781). In presence of  $H_2O$ , acts as a bleacher and disinfectant.

The atomic weight of Br has been determined (1) by analyses, and determinations of V. D., of many gaseous compounds, e.g.  $BrH$ ,  $BrCl$ ,  $Br_2Br$ ,  $Br_2Sn$ , &c.; (2) by determination of S. H. of solid  $Br_2$ ; (3) by comparison of bromides &c. with isomorphous chlorides and iodides &c.; (4) by syntheses of  $AgBr$  by Marignac (B. J. 21, 193); by syntheses of  $AgBr$  by Stas (Nouv. R. 168, 171); by reduction of  $AgBrO_3$  by Stas (Nouv. R. 199); by conversion of  $KBr$  to  $AgBr$  by Stas (L. 303); by conversion of  $AgBr$  to  $AgCl$  by Dumas (A. Ch. [3] 55, 162). In gaseous molecules containing Br the atom of Br is monovalent. Br acts as a strongly negative non-metallic element; it combines directly with most metals forming salts; its compounds with non-metals one of which is H are acids. The substitution of H by Br in carbon acids seems to increase the relative affinity of the acids (v. AFFINITY, p. 83); generally speaking, the introduction of Br in place of H in carbon compounds is accompanied by the production of more or less acidic properties.

In its chemical relations Br stands between Cl and I; the heat of formation, in solution, of a metallic bromide is usually about  $n$  11,000 gram-units less than that of the chloride, and about  $n$  26,000 gram-units more than that of the iodide, of the same metal, where  $n$  is a whole number, usually 1, 2, 3, or 4; metallic bromides are wholly or partly decomposed by Cl, and metallic iodides by Br; metallic chlorides are partially decomposed by Br (v. REACTIONS, No. 12). The relative affinities of the acids  $HCl$ ,  $HBr$ , and  $HI$  in aqueous solution are, however, nearly the same (v. AFFINITY, p. 77). In its compounds, Br appears to be positive to Cl, F, and O. No oxide of Br is at present known; the oxyacids of Br exist only in presence of water; they are much less stable than the oxyacids of iodine; one of the oxyacids of Cl ( $HClO_3$ ) has been obtained in separate and definite forms, although it is an extremely unstable compound; oxides of Cl are known as gases, and an oxide of I ( $I_2O_5$ ) exists as a solid body. No oxide or oxyacid of F is known (v. BROMIDES, HALOGEN ELEMENTS, and HALOGEN ELEMENTS, BINARY COMPOUNDS OF).

The S.G. of Br gas at  $99^\circ$  was found by Mitscherlich to be 5.54 (air = 1) and by Meyer a. Züblin to be 5.38 at  $100^\circ$ ; the S.G., calcu-

lated on the assumption that  $2 \times 79.75 = 159.50$  parts by weight of Br occupy 2 volumes, is 5.61. At very high temperatures (approximately  $1570^\circ$ ) the S.G. is less than the calculated; Meyer a. Züblin (B. 13, 405) obtained values lying between those calculated from the formula  $Br_2$  and  $\frac{1}{2} Br_2$ ; when the Br was obtained by decomposing  $PtBr_4$  at high temperatures the S.G. at  $1570^\circ$  nearly agreed with that calculated for  $\frac{1}{2} Br_2$  (3.66). The S.G. of Br vapour diluted with 10 volumes air, at  $50^\circ$  under the B.P. of Br, was determined by Langer a. Meyer to be 5.52 (B. 15, 2769). Jahn's determinations (B. 15, 1238) show that bromine does not attain the S.G. calculated for  $Br_2$  until it is heated about  $160^\circ$  above its B.P.; the deviations are small; the S.G. at any temperature up to about  $220^\circ$  may be approximately found by the formula  $S.G. = a + bt$ , where  $a = 5.8691$  and  $b = -.00153$ . (For S.G. of Cl and I gases v. these elements; v. also HALOGEN ELEMENTS.)

Reactions. —1. Br dissolves in water with production of heat  $[Br, Aq] = 1080$  (Th. [2] 25); the water is slowly decomposed, more quickly in direct sunlight, with formation of  $HBr$  and O. Bromine water, therefore, acts as an oxidiser; e.g.  $HNO_3Aq$  is oxidised to  $HNO_3Aq$  (Schönbein, J. pr. 37, 144),  $Mn(C_2H_3O_2)_2Aq$  to  $MnO_2$  (Kammerer, B. 4, 218); sugar, mannite, benzene, &c., &c., to various oxidised derivatives (Blomstrand, A. 123, 248). If NO is led into Br cooled below  $0^\circ$  the gas is absorbed, and on adding water  $HBr$  and higher oxides of N are formed (Landolt, A. 116, 177).—2. Steam mixed with Br and passed through a red-hot tube yields  $HBr$  and O.—3. Hydrogen peroxide evolves O, and  $HBr$  is formed (Schönbein, A. 108, 169).—4. Aqueous solutions of potash or soda are decomposed by Br forming  $KBrAq$  (or  $NaBrAq$ ) and  $KBrO_3Aq$  (or  $NaBrO_3Aq$ );  $CaO$  and  $BaO$  form bromides and O.—5. Aqueous ammonia yields  $NH_4BrAq$  and N.—6. Urea is decomposed by  $BrAq$  with evolution of N.—7. Hydriodic acid and iodides in solution are decomposed by Br with formation of  $HBrAq$ , or  $MBrAq$ , and I.—8. Sulphuretted hydrogen yields  $HBr$ , and S which partly combines to form  $S_2Br_2$ ; this decomposition proceeds either in presence or absence of water (Naumann, B. 9, 1574).—9. In contact with excess of silver nitrate solution,  $AgBr$  and  $HBrO_3Aq$  are produced (Spiller, J. 1859, 67).—10. With carbon disulphide, crystalline  $C_2S_2Br_4$  is formed (Hell a. Urech, B. 15, 987). 11. Carbon compounds are usually acted on by Br; sometimes H is withdrawn, sometimes this is accompanied by substitution of Br, and sometimes more complete decomposition results.—12. Br partly decomposes metallic chlorides when heated in equivalent quantities to  $270^\circ$ – $300^\circ$ ; if the mass of Br is increased, the amount of decomposition increases up to a limit which is not passed by increasing the mass of Br, the temperature, or the time of action (Potilitzin, B. 14, 1044; 15, 918; 16, 3051). According to Hampidge (B. 17, 1838)  $AgCl$  is partly decomposed by contact with water and an equivalent quantity of Br; thus 5.2 p. c. Cl was removed from  $AgCl$  after 24 hours' action at  $11^\circ$ , and 14.53 p. c. after 12 hours' action at  $41^\circ$ .

Combinations.—1. With water at  $4^\circ$  forming red octahedral crystals of  $Br.10H_2O$  which are

decomposed to Br and  $H_2O$  at  $15^\circ$  (Löwig, *P.* 14, 114; 10, 875). For dissociation-pressures *v.* Roseboom (*R. T. C.* 4, 65).—2. Combines directly with most of the elements, especially the metals, often with production of much heat and sometimes light (*v.* BROMIDES). Does not combine directly with C or O. According to Merz a. Weith (*B.* 6, 1518) dry Br and Na do not combine even at  $200^\circ$ . Combines with liquid Cl at  $-30^\circ$  (Donny a. Mareska, *C. R.* 20, 817). No oxide of Br is at present known.

**Detection.**—The physical properties of Br enable this body to be easily detected when uncombined. Bromides are decomposed by  $ClAq$ , giving Br and chloride of the metal. Solution of  $N_2O$  in conc.  $H_2SO_4Aq$  does not decompose bromides, but does decompose iodides with production of  $I_2$ ; on this reaction is based a method for detecting bromides in presence of iodides. Solid bromides are decomposed by heating with  $K_2Cr_2O_7$  and conc.  $H_2SO_4Aq$ , with formation of Br; chlorides yield  $CrO_2Cl_2$ .

**Estimation.**—Free Br may be estimated volumetrically by measuring the  $I$  set free by it from  $KIAq$ , or by finding the mass of  $As_2O_3$ , which it oxidises to  $As_2O_5$  in an alkaline solution; Br may also be combined with  $H_2$  to form  $HBrAq$ , by treatment with  $H_2S$  or  $SO_2$  in aqueous solutions; the  $HBr$  may then be estimated by ppt. with  $AgNO_3Aq$ . Br in bromides is usually estimated as  $AgBr$ , ppt. being accomplished by addition of  $AgNO_3Aq$ ; in soluble bromides may be fused with  $Na_2CO_3$  dissolved, and acidulated with  $HNO_3Aq$ . In presence of chlorides, or iodides, Br in bromides must be determined by indirect methods (*v.* Manuals of Analysis).

**Bromine, Chloride of.**  $BrCl$ . Mol. w. unknown. Chlorine is absorbed by Br with formation of a red yellow, mobile, very volatile, liquid, which gives off a dark yellow, very irritating, vapour with strong bleaching properties; many metals burn in this vapour to chloride and bromide (Balard, *A. Ch.* 2, 32, 371). If the Br is cooled to  $0^\circ$  the liquid finally contains Br and Cl in the proportion  $BrCl$ ; at ordinary temperatures less Cl than is required by the composition  $BrCl$  is absorbed (Bornemann, *A.* 189, 183). At temperatures above  $+10^\circ$  the compound  $BrCl$  decomposes with evolution of Cl. By adding a little  $H_2O$  to  $BrCl$ , and cooling to  $0^\circ$ , yellow-brown crystals of  $BrCl \cdot 10H_2O$  separate (Bornemann, *l.c.*); these melt at  $7^\circ$ , and are decomposed by  $NH_3$  to  $N$ ,  $NH_4Br$ , and  $N$  chloride (Löwig, *Di. Brom und seine chemischen Verhältnisse*; Heidelberg, 1829, p. 64). An aqueous solution of  $BrCl$  obtained by dissolving Br in  $ClAq$ , is decomposed by alkalis giving alkali bromate and chloride; in sunlight  $HBrO_3Aq$  and  $HClAq$  are formed; reducing agents, *e.g.*  $SO_2Aq$ , Zn powder, Fe filings,  $P$ ,  $NO$ , &c., withdraw Cl, and set Br free (Schönbein, *J. pr.* 88, 483).

**Bromine, Cyanide of:** better called Cyanogen Bromide, formed by action of Br on  $Hg(CN)_2$ ,  $KCN$ , or  $HGN$ ; *v.* CYANIC ACIDS, vol. ii, p. 313.

**Bromine, Hydrate of.**  $Br \cdot 10H_2O$ . Obtained by cooling a saturated solution of Br in  $H_2O$ ; *v.* BROMINE; Combinations, No. 1.

**Bromine, Iodide of:** better called Bromide of Iodine; *v.* IODINE.

**Bromine, Oxyacids of.** No oxide of Br is known. The acids  $HBrO$  and  $HBrO_3$  exist in aqueous solutions only; both solutions are decomposed on heating,  $HBrO_3Aq$  even at  $80^\circ$ . Perbromic acid,  $HBrO_4$ , was said by Kämmerer to be produced by the action of Br gas on  $HClO_4Aq$  (*J. pr.* 90, 190); but later experiments have shown that this acid has not yet been obtained (*v.* Pattison Muir, *C. J.* 30, 469; MacIvor, *C. N.* 33, 35; Wolfram, *A.* 198, 95).  $BrAq$  is not oxidised by such reagents as  $KMnO_4Aq$ ,  $K_2Cr_2O_7Aq$ ,  $HNO_3Aq$ , or  $HClO_4Aq$ ; but the action of  $HClO_4Aq$  or  $HClO_3Aq$  produces  $HBrO_3Aq$ . Dilute solutions of  $HBrO$  and  $HBrO_3$  are also formed by electrolysis,  $HBrAq$ ,  $MBrAq$ , or  $BrAq$ ; also by the action of metallic oxides on  $BrAq$ . No salts of  $HBrO$  are known except in aqueous solutions; salts of  $HBrO_3$  exist as solids, they are all easily decomposed by heat with evolution of  $O$ , and frequently also of Br. The addition of  $O$  to  $KBrAq$  would be attended by disappearance of much heat; Thomsen gives these numbers [ $KBrAq$ ,  $O$  = 15,930; also  $Br_2O_3Aq$  = 16,200]. The following data show that the heat of formation of the oxyacids of Br is less than that of  $HBr$ , and is also less the more  $O$  the acid contains:— $[HBrAq]$  28,380;  $[HBrO_3Aq]$  26,080;  $[HBrO_4Aq]$  12,120 (*Th.* 2, 406). These data are analogous with those for the corresponding compounds of Cl, but differ from the data for the similar compounds of  $I$  (*v.* HALOGEN ELEMENTS).

**I. Hypobromous Acid, and Hypobromites.**  $HBrOAq$  and  $MBrOAq$ . Gay Lussac obtained a gas by the action of Br on dry  $H_2O$  and supposed it to be an oxide of Br; Pelouze, and more recently Dancet (*C. J.* 15, 477), proved that only  $O$  is thus produced. An aqueous solution of  $HBrO$  is obtained by the action of  $BrAq$  on the oxide, or nitrate, of  $Hg$ , or  $Ag$ ;  $H_2O$  and  $PbO$  do not oxidise  $BrAq$  (Spiller, *C. N.* 6, 249).

**Formation.** By the action of  $BrAq$  on  $H_2O$ —repeating several times  $H_2OBr$ ,  $HBrOAq$ , and  $H_2BrOAq$  are formed; by distilling *in vacuo*, a liquid containing 6·2 p.c. Br as  $HBrO$  is obtained, but it cannot be quite freed from  $H_2BrO$  (Balard, *A. Ch.* 32, 337).

**Preparation.**—Pure  $BrAq$  is shaken with excess of  $AgNO_3Aq$  until the colour and odour of Br have gone; the straw-coloured liquid is then at once distilled *in vacuo*; at 60 mm. pressure it boils at  $40^\circ$ . The distillate gets richer in  $HBrO$  until 736 p.c. Br is present as  $HBrO$  (then it gets poorer in the acid); about 46 p.c. of the Br used is changed to  $HBrO$ .

**Properties and Reactions.** Solution with 6·2 p.c. Br as  $HBrO$  decomposes at  $30^\circ$  giving Br and  $HBrO_3Aq$ ; solution with 736 Br as  $HBrO$  decomposes, into the products, at  $60^\circ$ .  $HBrOAq$  is a strongly bleaching liquid; it is decomposed by  $Ag_2O$  (and slowly by contact with  $AgNO_3Aq$ ) with formation of  $O$  and  $AgBr$ , by  $H_2O_2Aq$  with evolution of  $O$ ; and by  $HClAq$ ,  $HBrAq$ , and  $HIAq$ , with formation of Br (Schönbein, *J. pr.* 88, 475).

No hypobromites have been obtained except in dilute aqueous solutions. By the action of alkalis, alkali carbonates, or phosphates (Fritzsche, *A.* 40, 251), on  $BrAq$ , yellow, strongly bleaching, liquids are produced; these

liquids are very unstable, decomposing in air, quickly at 30°. They decompose urea with evolution of N<sub>2</sub>:  $\text{CON}_2\text{H}_4 + 3\text{HBrO}_2\text{Aq} = \text{CO}_2 + \text{N}_2 + 3\text{HBrAq} + 2\text{H}_2\text{OAq}$  (E. Knop, *C. C.* 1870, 132). Balard (*A. Ch.* 32, 337; *J. pr.* 4, 165) described bodies resembling bleaching powder, obtained by the action of BrAq on  $\text{CaOH}_2$  and  $\text{BaOH}_2$ ; by the addition of water and filtration, bleaching solutions were produced, very unstable, and easily decomposed, even by  $\text{CO}_2$ .

**II. BROMIC ACID AND BROMATES.**  $\text{HBrO}_3\text{Aq}$  and  $\text{MBrO}_3$ . Bromic acid,  $\text{HBrO}_3$ , is known only in aqueous solution.

**Formation.** 1. By electrolysis of  $\text{HBrAq}$  (Riche, *C. R.* 46, 318). 2. By action of heat on hypobromites in solution.

**Preparation.**  $\text{BaBrO}_3$  is prepared by adding Br little by little to conc.  $\text{BaOH}_2\text{Aq}$  until the liquid is slightly red, when  $\text{BaBrO}_3$ , pps. and  $\text{BaBr}_2$  remains in solution. The  $\text{BaBrO}_3$  is crystallised from hot water, dried, and ground to fine powder; 100 parts are digested for some time in the cold or at a very gentle heat, with 24 parts conc.  $\text{H}_2\text{SO}_4$  mixed with 240 parts  $\text{H}_2\text{O}$ ; excess of  $\text{H}_2\text{SO}_4$  is removed from the liquid by gradual addition of  $\text{BaOH}_2\text{Aq}$ ; the acid liquid is evaporated *in vacuo* (Rammelsberg, *A.* 40, 147). Kämmerer passes  $\text{Cl}_2\text{O}$  into Br under  $\text{H}_2\text{O}$  until the colour of the Br has disappeared;  $5\text{Cl}_2\text{O} + \text{Br}_2\text{Aq} + \text{H}_2\text{O} = 2\text{HBrO}_3\text{Aq} + 10\text{HClAq}$  (*J. pr.* 85, 452).

**Properties and Reactions.**  $\text{HBrO}_3\text{Aq}$  may be concentrated *in vacuo* until the liquid contains 50-59 p.c.  $\text{HBrO}_3$ ; the composition then nearly agrees with the formula  $\text{HBrO}_3 \cdot 7\text{H}_2\text{O}$ . When concentrated by heating in an open vessel decomposition begins when the liquid contains 4-27 p.c.  $\text{HBrO}_3$ , with production of Br, O, and  $\text{H}_2\text{O}$ .  $\text{HBrO}_3\text{Aq}$  is a colourless, acid liquid, with a bromine-like smell. Oxidisable bodies decompose  $\text{HBrO}_3\text{Aq}$  with separation of Br; e.g.  $5\text{SO}_2 + 2\text{HBrO}_3\text{Aq} + 4\text{H}_2\text{O} = 5\text{H}_2\text{SO}_4\text{Aq} + \text{Br}_2\text{Aq}$ ;  $5\text{H}_2\text{S} + 2\text{HBrO}_3\text{Aq} + 6\text{H}_2\text{OAq} + 5\text{S} + \text{Br}_2\text{Aq}$ . Iodine quickly decomposes  $\text{HBrO}_3\text{Aq}$ , forming  $\text{HIO}_3$  (Kämmerer, *J. pr.* 85, 452);  $\text{Cl}_2$ , dilute  $\text{H}_2\text{SO}_4\text{Aq}$ , and dilute  $\text{HNO}_3\text{Aq}$ , are without action.  $\text{HBrAq}$  decomposes  $\text{HBrO}_3\text{Aq}$ , forming  $\text{H}_2\text{O}$  and Br;  $\text{HClAq}$  and  $\text{HIAq}$  form  $\text{H}_2\text{O}$  and  $\text{BrCl}$  or  $\text{IBr}$ . The heat of neutralisation of  $\text{HBrO}_3\text{Aq}$  is the same as the mean value for the stronger monobasic acids;  $[\text{HBrO}_3\text{Aq} \cdot \text{NaOH Aq}] = 13,780$  (*Th.* 1, 240). Bromic acid is monobasic and forms one series of salts, the **bromates**,  $\text{MBrO}_3$  and  $\text{M}^2\text{BrO}_3$ ; these salts are formed by the action of  $\text{HBrO}_3\text{Aq}$  on the oxides, hydroxides, or carbonates, of the metals; the alkali and alkaline earth salts are also formed, always with bromides, by the action of Br on aqueous solutions of the alkali or alkaline earth hydroxides. (For special methods *v.* individual salts; also Kämmerer, *J. pr.* 85, 452.) The bromates crystallise well; they are all soluble in water; the least soluble are  $\text{AgBrO}_3$  and  $\text{HgBrO}_3$ . They are decomposed by heat; sometimes O is evolved and metallic bromide remains, e.g. bromates of alkalis, Hg, and Ag; sometimes Br and O are evolved, and oxide remains, e.g. bromates of Mg, Al, Zn; or a mixture of oxide and bromide remains, e.g. bromates of Pb, Cu, &c. Dilute  $\text{HNO}_3\text{Aq}$ ,  $\text{H}_2\text{SO}_4\text{Aq}$ , or

$\text{H}_3\text{PO}_4\text{Aq}$ , decomposes bromates giving  $\text{HBrO}_3\text{Aq}$  most of which decomposes to Br, O, and  $\text{H}_2\text{O}$ . Solutions of bromates react similarly to solution of  $\text{HBrO}_3$  towards  $\text{SO}_2$ ,  $\text{H}_2\text{S}$ ,  $\text{HClAq}$ ,  $\text{HBrAq}$ , and  $\text{HIAq}$ . The bromates have been chiefly investigated by Rammelsberg (*A.* 40, 147; *P.* 90, 16); Löwig (*B. J.* 12, 120); and Marignac (*C. R.* 45, 650; *J.* 1857, 127). The following are the better-studied salts.

**Barium bromate**  $\text{Ba}(\text{BrO}_3)_2 \cdot 12\text{H}_2\text{O}$ . Prismatic, monoclinic, crystals; isomorphous with  $\text{Ba}(\text{ClO}_3)_2$  (Marignac & Rammelsberg); S. (106°) 4·2; (15°-18°) 77. Prepared by decomposing  $\text{KBrO}_3\text{Aq}$  by  $\text{Ba}(\text{C}_2\text{H}_3\text{O}_2)_2\text{Aq}$ .

**Cadmium bromate**  $\text{Cd}(\text{BrO}_3)_2 \cdot \text{H}_2\text{O}$ . Columnar trimetric crystals; prepared by  $\text{CdSO}_4\text{Aq} + \text{BaBrO}_3\text{Aq}$ . S. (15°-18°) 125. On heating, leaves  $\text{CdO}$  and  $\text{CdBr}_2$  (Rammelsberg).

**Calcium bromate**  $\text{Ca}(\text{BrO}_3)_2 \cdot \text{H}_2\text{O}$ . Monoclinic plates (Marignac); prepared by  $\text{CaO}_2\text{H}_2\text{Aq} + \text{HBrO}_3\text{Aq}$ . S. (15°-18°) 99. Heated to 180° loses  $\text{H}_2\text{O}$ , at higher temperature gives O and  $\text{CaCl}$  (Rammelsberg).

**Cobalt bromate**  $\text{Co}(\text{BrO}_3)_2 \cdot 6\text{H}_2\text{O}$ . Transparent, hyacinth-coloured, monometric octahedra; prepared by  $\text{HBrO}_3\text{Aq} + \text{CoCO}_3$ , or  $\text{Ba}(\text{BrO}_3)_2\text{Aq} + \text{CoSO}_4\text{Aq}$ . S. (15°-18°) 45·5. Heated, gives  $\text{CoO}$  (Rammelsberg).

**Copper bromate**  $\text{Cu}(\text{BrO}_3)_2 \cdot 5\text{H}_2\text{O}$ . Blue-green crystals, efflorescing over  $\text{H}_2\text{SO}_4$  *in vacuo*; very soluble; lose  $\text{H}_2\text{O}$  completely, and a little Br also at 200°. Prepared similarly to  $\text{Co}(\text{BrO}_3)_2$ .

**Lead bromate**  $\text{Pb}(\text{BrO}_3)_2 \cdot \text{H}_2\text{O}$ . Small, lustrous, monoclinic prisms; isomorphous with  $\text{Sr}(\text{BrO}_3)_2 \cdot \text{H}_2\text{O}$  (Rammelsberg). S. (15°-18°) 1·33. Prepared by  $\text{HBrO}_3\text{Aq} + \text{PbCO}_3$ , or conc.  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2\text{Aq} + \text{KBrO}_3\text{Aq}$ . Heated over 180° gives Br,  $\text{PbO}_2$ , and  $\text{PbBr}_2$ , at higher temperatures gives  $\text{Pb}_2\text{O}_3$ , Br, and  $\text{PbBr}_2$ .

**Magnesium bromate**  $\text{Mg}(\text{BrO}_3)_2 \cdot 6\text{H}_2\text{O}$ . Large, efflorescent, monometric octahedra; S. (15°-18°) 71·5; loses all  $\text{H}_2\text{O}$  above 200°. Prepared by  $\text{MgO} + \text{HBrO}_3\text{Aq}$ , or  $\text{MgSiF}_6\text{Aq} + \text{KBrO}_3\text{Aq}$ .

**Mercury bromates**  $\text{Hg}_2(\text{BrO}_3)_2$  and  $\text{Hg}(\text{BrO}_3)_2 \cdot 2\text{H}_2\text{O}$ . Mercurous bromate is prepared by  $\text{Hg}(\text{NO}_3)_2\text{Aq} + \text{KBrO}_3\text{Aq}$  or  $\text{HBrO}_3\text{Aq} + \text{Hg}_2\text{O}$ ; mercuric bromate by  $\text{HBrO}_3\text{Aq} + \text{freshly ppd. HgO}$ . Both form small white crystals; the mercurous salt forms yellow basic  $\text{Hg}_2(\text{BrO}_3)_2 \cdot \text{Hg}_2\text{O}$  by the action of  $\text{H}_2\text{O}$ ; when heated it decomposes with detonation (Rammelsberg). The mercuric salt decomposes at 130°-140°, with slight explosion, to  $\text{HgO}$ ,  $\text{HgBr}_2$ , and  $\text{Hg}_2\text{Br}_2$ . S. (16°-18°) 17, (100°) 1·6.

**Nickel bromate**  $\text{Ni}(\text{BrO}_3)_2 \cdot 6\text{H}_2\text{O}$ . Prepared as is isomorphous with, and generally resembles, the Co salt (*q. v.*). S. (15°-18°) 28. (Rammelsberg; *v.* also Marbach, *P.* 94, 412).

**Potassium bromate**  $\text{KBrO}_3$ . Prepared by adding Br, or  $\text{BrCl}$ , to conc.  $\text{KOH Aq}$ ; or by adding Br to  $\text{K}_2\text{CO}_3\text{Aq}$  which has been previously saturated with  $\text{Cl}$ . Rhombohedra (Rammelsberg; Marignac, *J.* 1859, 139; *v.* also for crystalline forms, Löwig, *B. J.* 12, 120; Fritzsche, *A.* 40, 251; Marbach, *P.* 94, 412). S.G.  $\frac{4}{15}$  3·271 (Kremers, *P.* 99, 443). S. (0°) 3·1, (20°) 6·9, (40°) 13·2, (100°) 50 (Kremers, *P.* 97, 1). Insol.

in alcohol. B. P. of saturated  $\text{KBrO}_3 \text{ Aq} = 104^\circ$ .  $\text{KBrO}_3$ , when heated, melts at  $350^\circ$ , then begins to decompose, at first slowly, then rapidly and explosively, with evolution of O and a little Br. According to Fritzsche (A. 40, 251), crystals of  $\text{KBrO}_3$  prepared from exactly neutral solutions, or from solutions containing a little acetic acid, decrepitate before decomposing, and lose 1.3 p.c. of their mass (chiefly water); if the resulting powder is placed in warm water, O is evolved at the surfaces of the undissolved particles, but most of the O is again absorbed by the liquid; on evaporation, pure  $\text{KBrO}_3$  crystallises out. Fritzsche supposes that  $\text{KBrO}_3$  is partly decomposed by heat to hypobromite and perbromate, that the latter acts on water, evolving O and forming  $\text{KBrO}_3 \text{ Aq}$ , and that the O is absorbed by the  $\text{KBrO}_3 \text{ Aq}$  with formation of  $\text{KBrO}_3 \text{ Aq}$ .  $\text{KBrO}_3$  is decomposed by conc.  $\text{H}_2\text{SO}_4 \text{ Aq}$  with evolution of O and Br (Löwig); by  $\text{HNO}_3 \text{ Aq}$  with production of  $\text{KNO}_3 \text{ Aq}$ , Br, and O (Penny, A. 37, 206).  $\text{KBrO}_3 \text{ Aq}$  decomposes  $\text{H}_2\text{S}$ , separating S, and forming  $\text{HBr Aq}$ , and  $\text{H}_2\text{SO}_4 \text{ Aq}$ . Heated with combustible bodies,  $\text{KBrO}_3$  evolves O rapidly and explosively.

*Silver bromate*  $\text{AgBrO}_3$ . Dimetric prisms (Marignac). Prepared by  $\text{AgNO}_3 \text{ Aq} + \text{HBrO}_3 \text{ Aq}$  or  $\text{KBrO}_3 \text{ Aq}$ , and crystallising from hot water. Stable in air free from organic matter. Decomposes on heating.

*Sodium bromate*  $\text{NaBrO}_3$ . Prepared as  $\text{KBrO}_3$ . At  $4^\circ$  crystallises with  $\text{H}_2\text{O}$  forming efflorescent needles (Löwig); above  $4^\circ$  the anhydrous salt separates, isomorphous with  $\text{KBrO}_3$ , according to Löwig (B. J. 12, 120, S.G. 3.339). S. (6°)  $28$ , ( $20^\circ$ )  $38.5$ , ( $60^\circ$ )  $62.5$ , ( $100^\circ$ )  $99$  (Kiemers, P. 97, 1). B. P. of saturated  $\text{NaBrO}_3 \text{ Aq} = 109^\circ$ . Decomposes when heated as  $\text{KBrO}_3$  (q.v.).

*Strontium bromate*  $\text{SrBrO}_3 \cdot \text{H}_2\text{O}$ . Monoclinic prisms. Is amorphous with the Ba salt (Rammelsberg). S. ( $15^\circ$ – $18^\circ$ ) 33. Loses  $\text{H}_2\text{O}$  at  $120^\circ$ . Prepared by  $\text{SrCO}_3 + \text{HBrO}_3 \text{ Aq}$ .

*Zinc bromate*  $\text{ZnBrO}_3 \cdot 6\text{H}_2\text{O}$ . Monometric octahedra, isomorphous with the Mg salt; prepared as  $\text{CuBrO}_3 \cdot 6\text{H}_2\text{O}$ . Melts at  $100^\circ$ ; loses  $6\text{H}_2\text{O}$  at  $200^\circ$  with partial decomposition to  $\text{ZnO}$ , Br, and O. S. ( $15^\circ$ – $18^\circ$ ) 100. Soluble in  $\text{NH}_4 \text{ Aq}$  (Rammelsberg).

Besides the foregoing bromates of Ce, La, and Bi of the form  $\text{MBrO}_3 \cdot 6\text{H}_2\text{O}$  have been prepared (Rammelsberg, Matignon, Hermann J. pr. 82, 385). Bromates of Al, Cr, Fe, and V; of Pb and Pt; of Bi; and of Sn seem to exist. They have, however, either not been obtained in definite form, or have been very slightly examined.

**Bromine Sulphide**: of better called **Sulphur Bromide** (v. STURM). M. M. P. M.

**BROMINE ACTION ON ORGANIC BODIES** v. BROMO-COMPOUNDS.

**BROMO-**. Use of this prefix applied to inorganic compounds: for bromo-compounds and bromo-salts v. the element the bromo-compound of which is sought for, or the salts to the names of which bromo- is prefixed. Thus bromochloride of carbon will be found under CARBON; bromo-chromate of potassium under CHROMATES.

**BROMO-ACENAPHTHENE** v. ACENAPHTHENE.

**BROMO-ACENAPHTHYLENE** v. ACENAPHTHYLENE.

**BROMO-ACETAL** v. BROMO-ACETIC ALDEHYDE.

**BROMO-ACETAMIDE** v. BROMO-ACETIC ACID.

**BROMO-ACETAMIDE** v. Aceto-bromo-amide, p. 5.

**BROMO-ACETANILIDE** v. BROMO-ANILINE.

**BROMO-ACETANILIDE** v. BROMO-ANILINE.

**BROMO-ACETIC ACID**  $\text{C}_2\text{H}_3\text{BrO}_2$ , t.s. (Q) Br.CO.H. ( $51^\circ$ , ( $208^\circ$ )).

*Formation*.—1. By bromination of acetic acid (Perkin a. Dappa, A. 108, 106; Hell a. Mühlhauser, B. 11, 211; 12, 7.5). 2. By heating ethyl acetate with bromine at  $150^\circ$  (Crafts, A. 129, 501). 3. From glycolic acid and  $\text{HBr}$  (Kukulj, A. 130, 11). 4. By atmospheric oxidation of an alcoholic solution of bromo-ethylene (Glückner, A. Suppl. 7, 107). 5. By the action of bromine on dry glycerin (Barth, A. 121, 311). 6. From chloroacetic acid and  $\text{HBr}$  (Demole, B. 9, 561). 7. From ethylene bromide and fuming  $\text{HNO}_3$  (Kaelcher, M. 2, 239).

*Preparation*.—Br, glacial acetic acid, and some CS, are boiled with inverted condenser; the yield is nearly theoretical (Michael, Ann. 5, 202).

*Properties*.—Deliquescent rhombohedra; v. sol. water. Blisters the skin.

*Reactions*. 1. Heated with zinc it yields  $\text{Zn}(\text{OAc})_2$  and  $\text{ZnBr}$ . 2.  $\text{NH}_3$  forms glycocoll. 3. *Silver bromate* forms glycolide, benzoic acid and  $\text{AgBr}$ . 4. *Silver powder* at  $130^\circ$  forms succinic acid. 5. *Benzyl sulphide* ( $\text{C}_6\text{H}_5\text{S}$ ) forms benzyl bromide and  $\text{S}_2\text{C}_6\text{H}_5\text{CO.H}$  (Letts, Tr. E. 28, 612). Allyl sulphide acts similarly. 6. Bromoacetic acid and its ethyl salt unite directly with MeS and its homologues, forming hydrobromides of 'thetines' (Crum Brown a. Letts, B. 7, 695).

*Salts*.—The  $\text{NH}_4$ , K, Ba, and Ca salts are v. sol. water.  $\text{PhA}$ : harnia, sl. sol. cold water.  $\text{AgA}$ : crystalline; explodes at  $90^\circ$ .— $\text{UO}_2 \text{ NaA}$  (Clarke a. Owens, B. 11, 35).

*Methyl ether*  $\text{MeA}$  (144) (P. a. D.).

*Ethyl ether*  $\text{EtA}$  (159). Converted by Na into acetoacetic ether (v. p. 2).

*Chloroethyl ether*  $\text{CH}_2\text{ClCH}_2\text{A}$  (214). S.G. 1.165. From chloroethyl chloroacetate and Br (Henry, C. R. 97, 1308). Decomposed by heating with water into glycol chlorhydrin and bromoacetic acid.

*Bromo-ethyl ether*  $\text{CH}_2\text{CHBrO.CO.CH.Br}$  (135°) at 370 mm. S.G. 1.1962. From  $\text{C}_2\text{H}_5\text{CHClOAc}$  (v. p. 105) and Br at  $100^\circ$  (Kessl, B. 10, 1999; 11, 1916). Oil. Boiling alcoholic KOH forms bromoacetic ether,  $\text{EtBr}$ , acetal, and crotonic aldehyde.

*Di-bromo-ethyl ether*  $\text{C}_2\text{H}_4\text{Br}_2\text{O.CO.CH.Br}$ . A non-volatile oil, obtained by heating the preceding (1 mol.) with Br (1 mol.) at  $120^\circ$ .

*Tri-bromo-ethyl ether*  $\text{C}_2\text{H}_3\text{Br}_3\text{O.CO.CH.Br}$ . An oil formed by heating bromo-ethyl bromoacetic (1 mol.) with Br (2 mols.) at  $160^\circ$ .

*Tetra-bromo-ethyl ether*  $\text{C}_2\text{H}_2\text{Br}_4\text{O.CO.CH.Br}$  (177°). From the preceding (1 mol.) and Br (1 mol.) at  $170^\circ$ . Decomposed by alcohol into  $\text{EtBr}$  and bromo- and di-bromoacetic ethers.

*Penta-bromo-ethyl ether*  $\text{C}_2\text{HBr}_5\text{O.CO.CH.Br}$  (c.  $197^\circ$ ). Formed by brominating the preceding.

**Isocamyl ether C<sub>8</sub>H<sub>17</sub>O.** (200°).

**Chloride v. Bromo-acetyl chloride.**

**Bromide v. Bromo-acetyl bromide.**

**Anhydride (CH<sub>2</sub>Br.CO)<sub>2</sub>O.** (245°). Obtained by distilling Ac.O.CO.CH<sub>2</sub>Br which is formed by the action of AcONa on Br.CO.CH<sub>2</sub>Br (Naumann, A. 129, 273; Gal, C. R. 71, 273).

**Amide CH<sub>2</sub>Br.CO.NH<sub>2</sub>.** [165°]. From bromo-acetic ether and 20 p.c. NH<sub>3</sub> at 0° (Kessel, B. 11, 2116). V. sol. water, sl. sol. alcohol, insol. ether.

**Nitrile CH<sub>2</sub>Br.CN.** (149°). S.G. 1.21-1.771. V.D. 4.06. Bromo-acetonitrile is formed by the action of bromine-water on iodo-acetonitrile (Henry, C. R. 103, 413). The dibromide of acetonitrile (p. 35) may be looked upon as a hydrobromide of bromo-acetonitrile; when water is added to its alcoholic solution needles of the imide (CH<sub>2</sub>Br.CO).NH [98°] gradually separate (Engler, A. 133, 137; 142, 69).

**Di-bromo-acetic acid CHBr<sub>2</sub>.CO<sub>2</sub>H.** [45°-50°]. (283°). Formed, together with CH<sub>2</sub>Br.CO<sub>2</sub>H, when a mixture of bromine and acetic acid is exposed to sunlight (Perkin & Duppa, C. J. 11, 22; Schäffer, B. 4, 368). Formed also by the action of Br on acetic ether at 130° (Carius, B. 3, 386), and as a by-product in the preparation of tri-bromo-acetic aldehyde by passing bromine-vapour into alcohol. Crystalline mass, v. sol. alcohol and ether; its vapour is very pungent.

**Salts.** Excepting Ag and mercurous salts, the dibromo-acetates dissolve readily in water. NH<sub>4</sub>A', KA' m. BaA' hq. BaA' Ggq (Benedikt, A. 180, 160).—PbA': stellate groups of needles.—AgA': needles; decomposed by boiling water into AgBr, glyoxylic acid, and dibromo-acetic acid; decomposed by ether at 100° into AgBr and an oil, C<sub>2</sub>H<sub>3</sub>Br<sub>2</sub>O, whence water forms di-bromo-acetic and glyoxylic acids (Perkin, C. J. 82, 91).

**Ethyl ether CHBr<sub>2</sub>.CO<sub>2</sub>Et.** (193°). Formed by heating the acid with alcohol or by adding bromat-hydrate (4 pts.) to an alcoholic solution of KCy (1 pt.) (Remi, J. R. 7, 263).

**Amide CHBr<sub>2</sub>.CO.NH<sub>2</sub>.** [156°]. **Formation.**—1. From di-bromo-acetic ether and NH<sub>3</sub> (Schäffer, B. 4, 369; Kessel, B. 11, 2116).—2. From penta-bromo-aceto-acetic amide CBr<sub>2</sub>.CO.CBr<sub>2</sub>.CO.NH<sub>2</sub> and boiling water (Stokes & V. Peckmann, Am. 8, 375).—3. From penta-bromo-acetone and NH<sub>3</sub> (Clocz, A. 122, 121).—4. From asparagine and bromine (Guarreschi, B. 9, 1435). **Properties.**—Needles; may be sublimed; m. sol. cold, v. sol. hot, water, alcohol, and ether.

**Nitrile CHBr<sub>2</sub>.CN.** [112°]. Formed, together with bromoform and CO<sub>2</sub>, by the action of Br on aqueous cyano-acetic acid (Hoff, B. 7, 1571).

**Tri-bromo-acetic acid CBr<sub>3</sub>.CO<sub>2</sub>H.** [130°] (S.) [135°] (Gal, C. R. 77, 786). (250°).

**Formation.**—1. By the action of water on tri-bromo-acetyl bromide.—2. By heating aqueous malonic acid with bromine (Petrieff, B. 8, 730).—3. By heating tri-bromo-acetic aldehyde with HNO<sub>3</sub> (Schäffer, B. 4, 370).

**Properties.** Monoclinic tables, v. sol. water; its vapour is pungent. Decomposed by boiling, giving off Br and HBr. The salts, excepting the silver and mercurous salts, are v. sol. water and alcohol, but decomposed by heat, both when dry and when in solution, into bromoform and a metallic carbonate.

**Salts.**—KKA' 21gq; lustrous laminae. BaA' 8gq; tables.—PbA': stellate groups of needles.—AgA': very unstable laminae.

**Ethyl ether EtA'.** (225°).

**Amide CBr<sub>3</sub>.CO.NH<sub>2</sub>.** [121°]. Formed, together with the preceding by the action of bromine on asparagine suspended in water (Guarreschi, G. 6, 375). Formed also by treating hexa-bromo-acetone with ammonia (Weidel & Grüber, B. 10, 1148). Monoclinic laminae; may be sublimed; sl. sol. alcohol, ether, and cold water. Split up by boiling alkalis into bromo-form, CO<sub>2</sub>, and NH<sub>3</sub>.

**BROMO-ACETIC ALDEHYDES.**

**Bromo-acetic ortho-aldehyde.**

**Ethyl ether CH<sub>2</sub>Br.CH(OEt)<sub>2</sub>.** **Bromo-acetal.** (171°). From acetal and bromine (Pinner, B. 5, 119) or by treating vinyl ethyl oxide with Br and decomposing the product CH<sub>2</sub>Br.CHBr.OEt with NaOEt (Wislicenus, A. 192, 112). Alcoholic KOH at 170° converts it into CH<sub>2</sub>OH.CH(OEt)<sub>2</sub>, while NaOEt forms at 100° CH<sub>2</sub>(OEt).CH(OEt)<sub>2</sub>.

**Di-bromo-acetic aldehyde CHBr<sub>2</sub>.CHO.** (142°). Formed by dropping Br (2 mols.) into a solution of paraldehyde (1 mol.) in acetic ether (Hagemann, B. 3, 758; Pinner, A. 179, 67). Liquid, v. sol. water and alcohol. Blisters the skin. Slowly changes to an isomeric modification, m.-ol. water. Combines with water, forming the solid hydrate CHBr<sub>2</sub>.CH(OH)<sub>2</sub>.

**Tri-bromo-acetic aldehyde CBr<sub>3</sub>.CHO.**

**Bromal.** Mol. w. 281. (174°). S.G. 3.34.

**Formation.**—1. By the action of Br on alcohol (Lüwig, A. 3, 280; Schäffer, B. 4, 366).—2. Together with the preceding, by the bromination of paraldehyde.

**Properties.** Pungent liquid; decomposed by aqueous alkalis into bromoform and formic acid.

**Reactions.**—1. Fuming HNO<sub>3</sub> forms tri-bromo-acetic acid.—2. Alcoholic KCy forms di-bromo-acetic ether and HCl (Remi, J. 8, 695).—3. Conc. H<sub>2</sub>SO<sub>4</sub> forms bromalide C<sub>2</sub>H<sub>3</sub>Br<sub>2</sub>O, or tri-bromo-ethylidene tri-bromo-lactate

$$\text{CBr}_2\text{CH} \begin{array}{l} \diagup \text{O.CO} \\ \diagdown \text{O.CH.CBr}_2 \end{array} \quad [158^\circ].$$
 This body is

also formed by the action of tri-bromo-lactic acid on bromal (Wallach, A. 193, 52). It is insol. water, and decomposed by alcohol.—4. Tri-chloro-lactic acid forms the corresponding

$$\text{CBr}_2\text{CH} \begin{array}{l} \diagup \text{O.CO} \\ \diagdown \text{O.CH.CCl}_2 \end{array} \quad [150^\circ].$$
—5. **Lactic acid**

forms 
$$\text{CBr}_2\text{CH} \begin{array}{l} \diagup \text{O.CO} \\ \diagdown \text{O.CH.CH}_3 \end{array} \quad [97^\circ]$$
 (Klimenko, B. 9, 968).

**Combinations.**—1. With water: **Tri-bromo-acetic ortho-aldehyde or Bromal-hydrate** CBr<sub>3</sub>.CH(OH)<sub>2</sub>. [54°]. Crystallises on evaporating an aqueous solution of bromal. Decomposed by distillation into H<sub>2</sub>O and bromal.—2. With alcohol: CBr<sub>3</sub>.CH(OH)(OEt). **Bromal alcoholate** [44°]. Thick needles; sl. sol. water; resolved by distillation into its components.—3. With sodium bisulphite CBr<sub>3</sub>.CH(OH).SO<sub>2</sub>Na; laminae.—4. With ammonia CBr<sub>3</sub>.CH(OH).NH<sub>2</sub>; crystals, insol. water; decomposed at 35° (Schiff & Tassinari, B. 10, 1786).—5. With acetamide: CBr<sub>3</sub>.CH(OH).NHAc. [160°] (S. & T.).—6. With

ethyl carbamate:  $\text{CBr}_2\text{CH}(\text{OH})\text{NH}_2\text{CO}_2\text{Et}$ . *Bromal-urethane* (188°) (Bischoff, B. 7, 632).

**BROMO-ACETIC BROMIDE** v. **BROMO-ACETYL BROMIDE**.

**BROMO-ACETIC CHLORIDE** v. **BROMO-ACETYL CHLORIDE**.

**BROMO-ACETIC OXIDE** v. *Anhydride of Bromo-acetic acid*.

**BROMO-ACETO-ACETIC ACID** *Ethyl-ether*  $\text{C}_2\text{H}_5\text{BrO}$ , i.e.  $\text{CH}_3\text{CO}_2\text{CHBrCO}_2\text{Et}$ . S.G. 22 1.511.

**Formation.**—By addition of Br (1 mol.) to an ethereal solution of aceto-acetic ether (Duisberg, B. 15, 137; A. 213, 138).

**Properties.**—Pungent brown liquid; sl. sol. water, v. sol. ether and alcohol. Gradually decomposes on standing, giving off  $\text{HBr}$ .  $\text{FeCl}_3$  turns its aqueous solution deep red. It is dissolved by baryta-water, and on adding  $\text{Ca}(\text{OAc})_2$  the solution gives a sap-green crystalline pp.  $\text{Cu}(\text{C}_2\text{H}_3\text{BrO}_2)_2$ , which on recrystallisation from alcohol or  $\text{CS}_2$  separates as dark-green needles.

**Reactions.** 1. Alcoholic  $\text{NH}_3$  forms succinyl-succinic ether. 2. Na added to its ethereal solution also produces succinyl-succinic ether (dihydride of di-oxy-terephthalic ether). 3.  $\text{NaOEt}$  produces succinyl-succinic acid (Wedel, A. 219, 92). These reactions may be represented thus:  $2\text{C}_2\text{H}_5\text{CO}_2\text{CHBrCO}_2\text{Et}$

**Anilide**  $\text{CH}_3\text{CO}_2\text{CHBrCO}_2\text{NHPh}$ . (138°). Bromine added to the anilide of aceto-acetic ether in chloroform forms an additive product which on warming yields bromo-aceto-acetic anilide (Knorr, A. 236, 79). Pearly plates (from alcohol); sl. sol. water. Conc.  $\text{H}_2\text{SO}_4$  produces bromo-oxy-methyl-quinoline.

**Methyl-bromo-aceto-acetic ether**  $\text{CH}_3\text{CO}_2\text{CHBrCO}_2\text{Et}$ . Obtained by bromination of methyl-aceto-acetic ether. Liquid. Converted by heat into  $\text{EtBr}$  and  $\text{C}_2\text{H}_5\text{O}_2$  (Fawlow, C. R. 97, 99).

**Ethyl-bromo-aceto-acetic ether**  $\text{CH}_3\text{CO}_2\text{CHBrCO}_2\text{Et}$ . S.G. 1.35. Obtained by adding Br to ethyl-aceto-acetic ether in ethereal solution (Wedel, A. 219, 102). Pungent liquid.  $\text{FeCl}_3$  turns its alcoholic solution violet. At 100° it gives  $\text{EtBr}$  and  $\text{C}_2\text{H}_5\text{O}_2$  or  $\text{C}_2\text{H}_5\text{O}$ , probably  $\text{CH}_3\text{CO}_2\text{C}(\text{OCH}_2\text{CH}_2\text{CH}_2\text{CH}_3)_2$  (cf. Demarcay, A. Ch. 15, 20, 465).

**Iso-butyl-bromo-aceto-acetic ether**  $\text{CH}_3\text{CO}_2\text{C}(\text{C}_2\text{H}_5)_2\text{BrCO}_2\text{Et}$ . From iso-butyl-aceto-acetic ether and  $\text{Br}$  at -5° (Demarcay, Bl. [2] 31, 513; 33, 516; A. Ch. 15, 20, 433; C. R. 86, 1085, 1135). Alcoholic  $\text{KOH}$  converts it, according to Demarcay, into hexoic, methyl-isobutyl-glyceric, heptoic, oxheptoic, and glycolic acids; according to Fawlow (C. R. 97, 99) alcoholic  $\text{KOH}$  forms an acid  $\text{C}_6\text{H}_9\text{O}_7$  or  $\text{CH}_3\text{CO}_2\text{C}(\text{CO}_2\text{H})\text{CH}_2\text{Br}$  with evolution of  $\text{EtBr}$ .

**Di-bromo-aceto-acetic ether**  $\text{CH}_3\text{CO}_2\text{CBr}_2\text{CO}_2\text{Et}$  (?). S.G. 22 1.581. From aceto-acetic ether (10 g.) in ether (10 g.) treated with Br (24.6 g.) (Duisberg, A. 213, 143). Pungent oil.

**Reactions.**—1. Aqueous  $\text{FeCl}_3$  gives a deep

red colour.—2. *Baryta-water* gives a claret colour, but  $\text{Ca}(\text{OAc})_2$  gives no pp. in this solution. A sap-green pp.  $\text{Cu}(\text{C}_2\text{H}_3\text{BrO}_2)_2$  is, however, formed when conc.  $\text{Cu}(\text{OAc})_2$  is added to an alcoholic solution of the ether; it crystallises in needles (from alcohol).—3. Diluted with ether and treated with Na, di-bromo-aceto-acetic ether (80 g.) gives di-oxy-terephthalic ether (2 g.).  $\text{NaOH}$  may be used instead of Na (Wedel, A. 219, 74).

**Ethyl-di-bromo-aceto-acetic ether**  $\text{C}_2\text{H}_5\text{BrCO}_2\text{CHBrCO}_2\text{Et}$  (?). S.G. 1.64. A yellowish oil, got by bromination of ethyl-aceto-acetic ether.  $\text{FeCl}_3$  colours its alcoholic solution wine red (Wedel, A. 219, 102).

**Tri-bromo-aceto-acetic ether**  $\text{CH}_3\text{BrCO}_2\text{CBr}_2\text{CO}_2\text{Et}$ . S.G. 22 2.114. From aceto-acetic ether (10 g.) in chloroform (20 g.) by addition of bromine (38 g.) (Duisberg, A. 213, 145). Yellow liquid, slightly pungent. V. sl. sol. water. When heated, it gives off  $\text{HBr}$ .

**Reactions.**—1. Aqueous  $\text{FeCl}_3$  gives after some time a slight red pp. 2. Gives in alcoholic solution with cupric acetate a green pp.  $\text{Cu}(\text{C}_2\text{H}_3\text{BrO}_2)_2$  (Wedel, A. 219, 95).

**Ethyl-tri-bromo-aceto-acetic ether**  $\text{C}_2\text{H}_5\text{BrCO}_2\text{CBr}_2\text{CO}_2\text{Et}$  (?). S.G. 1.86. Its alcoholic solution is turned wine-red by  $\text{FeCl}_3$ .

**Tetra- and Penta-bromo-aceto-acetic ethers**, so called, are mixtures of tri- with per-bromo-aceto-acetic ether.

**Penta-bromo-aceto-acetamide**  $\text{CBr}_2\text{CO}_2\text{CHBrCO}_2\text{NH}_2$ . [e. 148°]. From di-oxy-amido-pyridine and bromine water (Stokes n. V. Pechmann, Ann. 8, 375). Needles or prisms; converted by boiling water into di-bromo-acetamide and  $\text{CHBr}_3$ . Alcoholic  $\text{NH}_3$  gives di-bromo-malonamide and  $\text{CHBr}_3$ .

**Per-bromo-aceto-acetic ether**  $\text{CBr}_3\text{CO}_2\text{CBr}_2\text{CO}_2\text{Et}$  [69° 70°]. From tri-bromo-aceto-acetic ether and bromine at 80° for 2 days. Colourless crystalline mass. Not affected by air. Gives no colour with  $\text{FeCl}_3$  and no copper pp. (Wedel, A. 219, 97).

**BROMO-ACETO-AMIDO-** v. *Bromo-amido-*.

**TRI-BROMO-ACETO-GUANAMIDINE**  $\text{C}_2\text{H}_3\text{Br}_3\text{N}_3\text{O}_2$ . From bromine and aqueous acetoguanamide (Neueki, B. 9, 236). Minute needles, insol. water, alcohol, and ether. Split up by boiling with water into bromoform and cyanuric acid.

**BROMO-ACETOL** v. *Di-bromo-terephthalic*.

**BROMO-ACETONE**  $\text{CH}_3\text{COCH}_2\text{Br}$ . S.G. 1.99. **Formation.** 1. By adding 1 mol. bromine to acetone, either pure or mixed with water or with  $\text{CS}_2$  (Linneemann, J. 125, 307; Emmerling, B. 6, 22). 2. By the action of a weak electric current on a mixture of acetone and  $\text{HBr}$  (Riche, C. R. 43, 276).

**Preparation.** 1. A stream of dry air saturated with bromine (158 g.) is passed through 100 g. cooled acetone (Emmerling n. Wagner, A. 204, 274). 2. Bromine (1 mol.) is passed through a solution of 1 mol. acetone in 10 vol. water (Sokolowsky, B. 9, 1687).

**Properties.**—Yellow, very pungent-smelling oil, quickly turning violet when dry, more permanent when mixed with a little water.  $\text{Ag}_2\text{O}$  oxidises it to formic and acetic acids (Linneemann, Sitz. B. 68, 137). Aqueous  $\text{K}_2\text{CO}_3$  forms

a syrupy acid  $C_2H_2O_6$  (7) Bromo-acetone combines with  $NaHSO_3$ .

**$\alpha$ -Di-bromo-acetone**  $CH_2Br.CO.CHBr_2$ . S.G. 2.5. Prepared by adding bromine (2 mols.) to acetone (1 mol.) mixed with a large quantity of water. Liquid, volatile with steam. Not very pungent. Combines with  $NaHSO_3$ .

**$\alpha$ -Di-bromo-acetone**  $CH_2Br.CO.CHBr_2$ . [24°]. From di-iodo-acetone and  $AgBr$  at 150°; or from di-chloro-acetone and aqueous  $KBr$ . Long needles with pungent smell (Völker, A. 192, 96). Reduced by  $Zn$  and  $H_2SO_4$  to acetone.

**Tri-bromo-acetone**  $CH_2Br.CO.CHBr_3$ . Formed by the action of alkalis upon hexa-bromo-methyl-methenyl di-ketone.  $NH_3$  gives bromoform (Combes, A. Ch. [6] 12, 241).

**Tetra-bromo-acetone hydrate**  $C_2H_2Br_4O_2aq$ . [43°]. From  $Ba$  (10 pts.) and acetone (1 pt.) in the cold; when the resulting solid mass is recrystallised from dilute alcohol a mixture of tetra- and penta-bromo-acetone is first deposited, and afterwards prisms of tetra-bromo-acetone hydrate  $C_2H_2Br_4O_2aq$ . The hydrate is insol. water, sol. alcohol (Mulder, J. 1864, 330). Perhaps this body is  $(C_2H_2Br_4O)HOEt$ .

**Penta-bromo-acetone**  $C_2H_2Br_5O$ . [76°].

**Formation.** 1. From  $Br$  (12 pts.) and acetone (1 pt.) (Mulder, J. 1864, 330; cf. Steiner, B. 7, 505, 1281). 2. Separates on adding water to an alcoholic solution of 'phlorobromin', that has stood some time (Benedikt, C. C. 1878, 101; A. 189, 168). 3. From potassic citraconate and  $Br$  (Cahours, A. 61, 351; Grimaux, J. 1871, 622). 4. From chelidonic acid and  $Br$  (Wilde, A. 127, 167). 5. From aqueous pyruvic acid and  $Br$  at 100° (Wichelhaus, A. 152, 260).

**Properties.**—Trimetric needles (from dilute alcohol);  $ab:bc = 698:1$ ; 686 (Ditscheiner a. Friedländer, Z. Kryst. 3, 103). Converted by aqueous or alcoholic  $NH_3$  into di-bromo-acetamido. Aqueous  $KOH$  forms bromoform,  $HBr$ ,  $CO_2$ , and formic acid.

**Hexa-bromo acetone**  $CHBr_2.CO.CBr_3$ . [112°].

**Formation.**—1. By the action of  $Br$  on an aqueous solution of tri-amido-phenyl hydrochloride or hydrobromide, or on 'bromo-dichromazin' the first product of the action of bromine on these salts. 2. From bromanilic acid and  $Br$  (Hantzsch a. Schmiter, B. 20, 2040). 3. From di-amido-guaiacol hydrochloride and  $Br$  (Herzig, M. 3, 825).

**Properties.**—Monoclinic prisms (from chloroform) insol. water. Decomposed by alcohol.

**Reactions.** 1. Boiling  $NaOH$  aq. or water at 180° form bromoform and  $CO_2$ . 2. Boiling conc.  $HNO_3$  has no action, but at 150° it produces bromo-picrin  $C_8H_5Br_3NO_3$ . 3. Dry  $NH_3$  gives rise to tri-bromo-acetamide and  $CH_2Br_2$ . 4. Sodium amalgam reduces it to iso-propyl alcohol.

**BROMO-ACETONITRILE** v. NITRILE OF BROMO-ACETIC ACID.

**$\alpha$ -BROMO-ACETOPHENONE**  $C_6H_5BrO$  i.e.  $C_6H_5.CO.CHBr$ . Phenyl bromo-methyl ketone. Phenacyl bromide. [50°].

**Formation.**—1. From acetophenone and  $Br$  Emmerling a. Engler, B. 4, 118; Hunnius, B. 0, 2006; Stadel, B. 13, 837). 2. Formed, together with  $CO$  and  $HBr$ , by boiling  $\alpha$ -phenyl-oxy- $\beta$ -dibromo-propionic acid with water Böttger, B. 14, 1238).

**Preparation.**—133 pts. of bromine are slowly run into a mixture of 100 pts. of acetophenone and 500 pts. of glacial acetic acid. After standing an hour it is gently heated on a water bath till colourless, when it is at once poured into a large quantity of cold water; the yield is 133 pts. or 80 p.c. of the theoretical (Möhlau, B. 15, 2464).

**Properties.**—Trimetric prisms (from dilute alcohol); pungent; v. sol. alcohol and ether, insol. water.

**Reactions.**—1.  $KMnO_4$  forms benzoic acid. 2. Alcoholic  $NH_3$  forms iso-indole  $C_8H_7N$ . 3. With *sodio-malonie ether* it forms  $C_6H_5.CO.CH_2.CH(CO_2H)_2$ . 4. With *sodio-acetoacetic ether* it forms acetophenone-aceto-acetic ether (v. p. 36). 5. Aniline forms phenyl-amido-acetophenone (Möhlau, B. 14, 172). 6. Reacts with hydroxylamine hydrochloride with production of iso-nitroso-acetophenone-oxim,  $C_6H_5.C(NO_2H).CH.NHOH$  [163°] (Schramm, B. 16, 2183). 7. An alcoholic solution of phenyl hydrazine reacts thus:  $Ph.CO.CHBr + N_2H_5Ph = HBr + H_2O + Ph.C.H.N.NhPh$ . The product forms yellow needles (from alcohol) [137°]. It is very soluble in ether, chloroform, and  $CS_2$ , less in alcohol or light petroleum. It is decomposed by acids (O. Hess, A. 232, 231).

**$\alpha$ -Di-bromo-acetophenone**  $C_6H_4Br_2.CO.CHBr_2$ . [37°]. Prepared by adding bromine (2 mols.) to a cold solution of acetophenone (1 mol.) in acetic acid, warming to 65°–70°, and pouring into water; the yield is c. 80 p.c. of the theoretical (Engler a. Hassenkamp, B. 18, 2240; cf. Hunnius, B. 10, 2010; Fittig a. Wurster, J. 195, 161).

**Properties.**—Trimetric tables (from  $CS_2$ ); insol. water. Oxidised by  $KMnO_4$  to benzoic acid.

**Reactions.** 1. Alcoholic  $KOAc$  forms  $Ph.CO.CH(OAc)_2$ . 2. Alcoholic *hydroxylamine* forms phenyl-glyoxim  $Ph.C(NO_2H).CH(NOH)$  [152°]. 3. By treatment with  $NH_3$ , a portion breaks up into benzamide and  $CH_2Br_2$ , whilst another part yields isodilucine  $C_{12}H_{12}N_2O$ .

**$\alpha$ -TRI-BROMO-ACETOPHENONE- $\alpha$ -CARBOXYLIC ACID**  $CHBr_2.CO.C_6H_4Br_3$ . [160°]. From phthalyl-acetic acid and  $Br$ . Resolved by alkalis into  $CHBr_2$  and phthalic acid (Gabriel a. Michael, B. 10, 1551, 2199; 11, 1007).

**BROMO-ACETOTHIENONE** v. THIENYL BROMO-METHYL KETONE and DI-METHYL THIENYL METHYL KETONE.

**HEXA-BROMO-ACETYL-ACETONE** v. HEXA-BROMO-DI-METHYL METHYLENE DI-KETONE.

**$\alpha$ -BROMO-ACETYL-BENZENE** is BROMO-ACETOPHENONE (q. v.).

**BROMO-ACETYL BROMIDE**  $CH_2Br.CO.Br$ . (150°). S.G. 2.317.

**Formation.**—1. From  $AcBr$  and  $Br$  at 100° (Gal, A. 129, 54). 2. From  $AcBr$  and  $PBr_3$  at 150° (Samosadsky, Z. [2] 6, 105). 3. From  $AcCl$  (64 pts.) and  $Br$  (120 pts.) at 100° (Hübner, A. 124, 315; Naumann, J. 129, 257; Gal, A. 132, 179). 4. By direct combination of  $\alpha$ -dibromo ethylene  $CH_2Br_2$  with oxygen (Demole, C. R. 86, 542).

**Properties.**—Pungent liquid; blisters the skin.

**Reactions.**—1. Aqueous  $Na_2CO_3$  forms sodium bromo-acetate and sodium glycolate. 2. Distillation with  $NaOAc$  produces  $Ac_2O$ , bromo-acetic anhydride and glycolide. 3.  $ZnMe_2$  gives a compound whence water liberates

methyl-isopropyl-carbinol, acetone, and methyl ethyl ketone (Winogradov, A. 191, 127).

**Di-bromo-acetyl bromide**  $\text{CHBr}_2\text{COBr}$ . (194°). From the preceding and Br at 150° (G.). Formed also by the action of oxygen on tri-bromo-ethylene (D.). Fuming liquid; converted by alcohol into di-bromo-acetic ether.

**Tri-bromo-acetyl bromide**  $\text{CBr}_3\text{COBr}$ . (220°-225°). From the preceding and Br at 200° (G.). Slowly converted by water into tri-bromo acetic acid.

**BROMO-ACETYL CHLORIDE**  $\text{CH}_2\text{BrCOCl}$ . S.G. 2.191. Pungent liquid, produced by the action of  $\text{PCl}_5$  on bromo-acetic acid (Wilde, J. 132, 171).

**BROMO-ACETYL CYANIDE**  $\text{CH}_2\text{BrCO.CN}$ . (70°). Formed, together with  $\text{CH}_3\text{CN.COBr}$  by the action of  $\text{AgCy}$  on bromo-acetyl bromide (Hübner, A. 131, 68). Monoclinic tablets, decomposed by water into  $\text{HCN}$  and  $\text{CH}_2\text{BrCO.H}$ .

**BROMO-ACETYLENE**  $\text{CHBrCH}$ . Formed by the action of alcoholic  $\text{KOH}$  on  $\text{CH}_2\text{Br.CBr}$  (Reboul, J. 125, 81), on  $\text{CH}_2\text{Br.CHBr}_2$  (Alexanderson, Z. 6, 614), or on  $\text{CHBr}_2\text{CHBr}$  (Sawitsch, A. 119, 183; Fontaine, C. R. 70, 1361; Sabatier, B. 2, 45, 245).

**Preparation.**—Acetylene dichloride is heated with  $\text{NaOH}$  and dilute alcohol in an apparatus filled with nitrogen. The gas is condensed by a freezing mixture (S.).

**Properties.**—Gas at ordinary temperatures; m. sol. water. In the liquid form it is decomposed by light into a tri-bromo-benzene and other products. It takes fire in air; when slowly mixed with air bromo-acetic acid is formed. Ammoniacal cuprous chloride gives a red ppt. of cuprous acetylide. Br forms  $\text{CHBr.CBr}$ .

**$\beta$ -BROMO  $\beta$ -ACETYL-PROPIONIC ACID**  $\text{C}_4\text{H}_5\text{BrO}_4$ , i.e.  $\text{CH}_3\text{CH}_2\text{COCHBrCH}_2\text{CO.H}$ . Bromo-lactic acid. (59°). Crystallised from  $\text{CS}_2$ .

**Formation.**—1. By bromination of a solution of  $\beta$ -acetyl-propionic acid in conc.  $\text{HCl}$  below 0°. 2. By the action of water upon ( $\alpha$ )-angelicalactone dibromide (Wolff, A. 229, 266; v. Drebrom- $\alpha$ -xy-valeric acid).

**Properties.**—White needles (from  $\text{CS}_2$ ). Sol. alcohol, ether, and water.

**Reactions.**—By the action of aqueous  $\text{NaCO}_3$  it yields oxy-acetyl-propionic acid and acetoacrylic acid. By heating with conc. aqueous  $\text{NH}_3$  at 110°-120° dimethyl ketone (tetramethylpyrazine)  $\text{C}_4\text{Me}_6\text{N}_2$  is formed, with evolution of  $\text{CO}_2$ . With aniline it gives di-phenyltetramethyl-di-hydro pyrazine  $\text{C}_4\text{Me}_6\text{N}_2\text{Ph}_2$  (Wolff, B. 20, 125).

**Ethyl ether EtAc.** (210°). S.G. 1.143. From Br and ethyl  $\beta$ -acetyl-propionate (Conrad a. Guthzeit, B. 17, 2285). Malonic ether and  $\text{NaOEt}$  convert it into methyl propyl ketone. Tricarboxylic ether  $(\text{COEt})_3\text{CH}_2\text{CH}_2\text{Ac.CH}_2\text{COEt}$  (c. 283°) S.G. 1.097.

**Di-bromo- $\beta$ -acetyl-propionic acid**  $\text{C}_4\text{H}_3\text{Br}_2\text{O}_4$ . (115°). Solidifies about 91°. From  $\beta$ -acetyl-propionic acid, chloroform and Br. From bromo- $\beta$ -acetyl-propionic acid and bromine. Long thin needles (Wolff, A. 229, 266; Hell a. Kehr, B. 17, 1981).

**Tri-bromo- $\beta$ -acetyl-propionic acid**  $\text{C}_4\text{H}_2\text{Br}_3\text{O}_4$ . (92°). From  $\beta$ -acetyl-propionic acid, Br and chloroform (Wolff, A. 229, 267).

**BROMO-pseudo-ACETYL-PYRROL** v. Bromo-PYRROL-METHYL KETONE.

**BROMO-ACETYL-UREA** v. UREA.

**BROMO-ACIDS** v. Bromo-compounds.

**BROMO-METACROLEIN**  $(\text{C}_4\text{H}_3\text{BrO}_2)_n$  (78°). Acrolein takes up Br forming di-bromo-propionic aldehyde, a liquid which polymerises, becoming a gummy mass, which may also be obtained by the action of Br on metacrolein.  $\text{NaOEt}$  converts this gummy metacrolein dibromide into bromo-metacrolein (Grimaux a. A. laun, B. 2] 36, 136). Needles (from alcohol). Has no smell; does not reduce Fehling's solut. n. When distilled with  $\text{H}_2\text{SO}_4$  (1 vol.) diluted with water (1 vol.) it gives off extremely pungent vapours which may be condensed to a liquid, sol. water, which is probably bromo-acrolein. By heating with  $\text{NaOEt}$  it is converted into  $\text{C}_4\text{H}_5\text{BrO}_4$  (140°).

**$\alpha$ -BROMO-ACRYLIC ACID**  $\text{C}_3\text{H}_3\text{BrO}_2$ , i.e.  $\text{CH}_2\text{BrCH=CO.H}$ . (50°). From  $\alpha$ - or  $\alpha$ -di-bromopropionic acid and alcoholic  $\text{KOH}$  (Philippi a. Tollens, J. 171, 333; Wagner a. Tollens, J. 171, 310; Erdemiryan, B. 11, 1867).

**Properties.**—Rectangular monoclinic plates, v. sol. water and alcohol. Decomposed by distillation or exposure to light. Combines with  $\text{HBr}$  forming  $\alpha$ -di-bromo propionic acid.

**Salts.**— $\text{AgAc}$ ,  $\text{EtAc}$ ,  $\text{Inq}$ ,  $\text{CaAc}$ ,  $\text{Inq}$ ,  $\text{KAc}$ ,  $\text{NaAc}$ ,  $\text{NH}_4\text{Ac}$ ,  $\text{ZnAc}$ .

**Ethyl ether EtAc.** (c. 157°). (77°) at 30 mm. With sodium malonic ether it gives  $\text{COEt}(\text{C}_4\text{H}_5\text{CH}_2\text{COEt})$ , identical with the compound from  $\alpha$ -di-bromo propionic ether and disodium-malonic ether (Michael, J. pr. [2] 35, 134).

**$\beta$ -Bromo-acrylic acid**  $\text{CHBrCH=CO.H}$  (116°). From bromalide or from tri-chloro-ethylidene tri-bromo lactate by reduction with  $\text{Zn}$  and  $\text{HCl}$  (Wallach, J. 193, 55). Formed also by the addition of  $\text{HBr}$  to propionic acid (Bandrowski, B. 15, 2703; Stolz, B. 19, 540). Plates or needles, sol. water and chloroform; explodes on heating.

**Acryl colloids.** This name is applied by Wagner a. Tollens to three bodies having the composition  $(\text{C}_3\text{H}_3\text{BrO}_2)_n$ .

**$\alpha$ -Acryl colloid.** Is formed in the preparation of  $\alpha$ -bromo acrylic acid from  $\alpha$ -di-bromo propionic acid, especially when the action becomes violent. Insol. water, alcohol, and ether, sol.  $\text{NH}_4\text{Ac}$  and not reppt. by  $\text{HCl}$ .

**$\beta$ -Acryl colloid** is formed when  $\alpha$ -bromo-acrylic acid is left over  $\text{H}_2\text{SO}_4$ . It is a porous mass, sol.  $\text{NH}_4\text{Ac}$  and reppt. by  $\text{HCl}$ .

**$\gamma$ -Acryl colloid** is formed with separation of  $\text{EtBr}$ , by heating ethyl  $\alpha$ -bromo-acrylate. Amorphous; insol.  $\text{NH}_4\text{Ac}$ , but becoming granular therein.

**$\alpha$ -Di-bromo-acrylic acid**  $(\text{CHBrCH=CO.H})_2$ . (85°). S. 519 at 18°.

**Formation.**—1. From  $\alpha$ -acetic acid and cold baryta-water (Jackson a. Hill, B. 11, 1673; Ann. 3, 111; 4, 169, 273; Phil a. Andrews, P. Soc. J. 16, 192; 17, 133). 2. From alcoholic  $\text{KOH}$  and  $\alpha$ -di-bromo-propionic acid (Michael a. Nott a. Ann. 2, 19; Mathner a. Suda, Sitz. B. 83, 273; M. 1, 104). 3. From  $\alpha$ -di-bromo-propionic acid and alcoholic  $\text{KOH}$ .

**Properties.**—Pearly plates (from alcohol). Sol. ether and chloroform, sl. sol. benzene and  $\text{CS}_2$ . Bodingbaryta-water form bromo acetylene, s.

# BROMO-ACRYLIC ACID

**CO<sub>2</sub>, formic, malonic, and bromo-propionic acids:** Heated with Br in a sealed tube it forms tetra-bromo-propionic acid.

**Salts.**—AgA': slender needles.—BaA<sub>2</sub>aq: pearly plates, sl. sol. cold water.—BaA<sub>2</sub>aq: S. 6-28 at 18°.—CaA<sub>2</sub>aq: long needles.—KA'.

**ββ-Di-bromo-acrylic acid** CBr<sub>2</sub>.CH.CO.H. [86°]. S. 3-66 at 20°. From tri-bromo-succinic acid by heating with water (Pittig a. Petri, A. 195, 70). Formed also by the union of HBr with bromo-propionic acid (Hill, B. 12, 660; Hill a. Mabery, P. Am. A. 16, 211).

**Properties.** Large plates; boils with partial decomposition at 243-256°. V. c. sol. alcohol, and ether; m. sol. cold water. Does not combine with HBr in the cold. Does not combine with Br in the cold, but at 100° it forms tetra-bromo-propionic acid (Mabery a. Robinson, Am. 5, 251).

**Salts.**—BaA<sub>2</sub> 2aq: S. 12-64.—CaA<sub>2</sub> 3aq.

**Ethyl ether EtA'**. (213°).

**Tri-bromo-acrylic acid** CBr<sub>3</sub>.CH.CO.H. [118°]. S. 1-37 at 20°. From αβββ-tetra-bromo-propionic acid and alcoholic KOH at 60° (Mauthner a. Snida, M. 2, 109). Formed also by treating bromo-propionic acid with bromine-water (Hill, Am. 3, 178); and from di-bromo-iodo-acrylic acid and Br at 100° (Mabery a. Lloyd, Am. 4, 92). Monoclinic prisms, *a:b:c* = 502:1:559 (Melville, P. Am. A. 17, 151). Triclinic pyramids, *a:b:c* = 1:128:1:150; *α* = 89° 13', *β* = 62° 26', *γ* = 91° 14' (Becke, M. 2, 111). V. sol. alcohol and ether. Does not combine with bromine, even at 200°. The Ba salt yields tri-bromo-ethylene when boiled with water.

**Salts.** BaA<sub>2</sub> 5aq. BaA<sub>2</sub> 3aq. S. (of BaA<sub>2</sub>) 80-6.—CaA<sub>2</sub> 3aq. AgA'.

**BROMO-ADIPIC ACID** C<sub>6</sub>H<sub>4</sub>BrO<sub>2</sub>. From adipic acid and Br (1 mol.) at 160° (Gal a. Gay-Lussac, C. R. 70, 1175). Dark-brown mass, smelling like camphor; converted by boiling alkalis into adipomalic (or oxyadipic?) acid (v. p. 61).

(a)-di-bromo-adipic acid C<sub>6</sub>H<sub>4</sub>Br<sub>2</sub>O<sub>2</sub>. From adipic acid and Br (2 mols.) at 160° (G. a. G.). Powder; decomposed by water. Water at 150° forms adipotartaric (or di-oxy-adipic?) acid (v. p. 61).

(β)-di-bromo-adipic acid C<sub>6</sub>H<sub>4</sub>Br<sub>2</sub>O<sub>2</sub>. [115°-122°]. Formed together with bromo-hydromuconic acid, by the action of Br on a solution of hydromuconic acid (Limprieh, A. 165, 265). Needles. Converted by moist Ag<sub>2</sub>O or baryta into di-oxy-adipic acid.

(γ)-di-bromo-adipic acid C<sub>6</sub>H<sub>4</sub>Br<sub>2</sub>O<sub>2</sub>. [175°-190°]. Formed by adding Br to a warm solution of hydromuconic acid in glacial HOAc (L.). Small needles. Converted by moist Ag<sub>2</sub>O into muconic acid, and by sodium-amalgam to hydromuconic acid.

**Tri-bromo-adipic acid** C<sub>6</sub>H<sub>4</sub>Br<sub>3</sub>O<sub>2</sub>. [177°-180°]. Formed by treating a hot solution of hydromuconic acid with excess of Br (L.). Small needles. Converted by boiling baryta-water into tri-oxy-adipic acid.

**Tetra-bromo-adipic acid** C<sub>6</sub>H<sub>4</sub>Br<sub>4</sub>O<sub>2</sub>. [211°]. Formed by heating hydromuconic acid with Br and water at 100°. Crystalline. V. sl. sol. water, v. sol. alcohol.

H. W.

\* **BROMO-ESCULETTIN** v. ESCULETTIN, p. 65.

# BROMO-ALLYL

**BROMO-ALLYL** v. BROMO-ALLYL AMINE.  
**HYD.**  
**BROMO-ALIZARIN** v. BROMO-DI-OXY-ANTHRAQUINONE.

**DI-BROMO-DIALLYL** v. Di-BROMO-HEXADIENE.

**BROMO-ALLYL ACETATE** C<sub>3</sub>H<sub>5</sub>BrOAc i.e. CHBr.CH<sub>2</sub>CH<sub>2</sub>OAc (?). [164°]. S.G. 1.157. From bromo-allyl bromide (β-epidibromhydrin) and alcoholic KOAc (Henry, B. 5, 453). Fragrant liquid; not attacked by PCl<sub>5</sub>. H. W.

**α-BROMO-ALLYL ALCOHOL** C<sub>3</sub>H<sub>5</sub>BrO i.e. CH<sub>2</sub>CHBr.CH<sub>2</sub>OH. (152°). From α-bromo-allyl bromide (α-epidibromhydrin) and water at 130° (Henry, B. 14, 403). Liquid; converted by aqueous KOH into propargyl alcohol.

**β-Bromo-allyl alcohol** CHBr.CH<sub>2</sub>CH<sub>2</sub>OH (?). (155°). S.G. 1.156. From β-bromo-allyl acetate (v. sup.) by distillation with solid NaOH (Henry, B. 5, 453). Is perhaps identical with the preceding.

**DI-BROMO-DI-ALLYL-AMINE** C<sub>6</sub>H<sub>8</sub>Br<sub>2</sub>N i.e. (C<sub>3</sub>H<sub>5</sub>Br)<sub>2</sub>NH. From s-tri-bromo-propane (tribromhydrin) and alcoholic NH<sub>3</sub> at 100° (Maxwell Simpson, P. M. [4] 16, 257). Also from bromo-allyl bromide and alcoholic NH<sub>3</sub> (Reboul, A. Suppl. 1, 232). Alkaline liquid, v. sl. sol. water. Converted by alcoholic NH<sub>3</sub> at 250° into methyl-pyridine.—B<sub>2</sub>H<sub>4</sub>PtCl<sub>6</sub>.—B<sub>2</sub>H<sub>4</sub>Cl<sub>2</sub>.

**BROMO-ALLYL BROMIDE** v. DI-BROMO-PROPYLENE.

**BROMO-ALLYLENE** v. PROPARGYL BROMIDE.

**Bromo-diallylene** v. HEXONYL BROMIDE.

**BROMO-ALLYL ETHYL OXIDE** v. ETHYL

BROMO-ALLYL OXIDE.

**BROMO-ALLYL NITRATE**

CHBr.CH<sub>2</sub>CH<sub>2</sub>O.NO<sub>2</sub> (?). (140°-150°). S.G. 1.155. From β-bromo-allyl bromide and AgNO<sub>3</sub> (Henry, B. 5, 452).

**BROMO-ALLYL OXIDE** C<sub>3</sub>H<sub>5</sub>Br<sub>2</sub>O i.e. (CHBr.CH<sub>2</sub>CH<sub>2</sub>)<sub>2</sub>O (?). *Bromo-allyl ether*. (c. 214°). S.G. 1.17. Formed together with propargyl alcohol from β-bromo-allyl alcohol and solid KOH (Henry, B. 6, 729).

**BROMO-ALLYL THIO-CARBIMIDE**

C<sub>3</sub>H<sub>5</sub>Br<sub>2</sub>NCS. (c. 200°). From bromo-allyl bromide and alcoholic potassium sulphocyanide (Henry, B. 5, 188).

**BROMO-ALLYL-THIO-UREA**

(C<sub>3</sub>H<sub>5</sub>Br)<sub>2</sub>NH.CS.NH<sub>2</sub>. [111°]. From the preceding and ammonia (H.).

**TRI-BROMO-ALOIN** v. Aloin, p. 141.

**BROMO-AMIDO-ACETOPHENONE**

[52:1] C<sub>6</sub>H<sub>4</sub>Br(NH<sub>2</sub>).CO.CH<sub>3</sub>.

*Acetyl derivative*

C<sub>6</sub>H<sub>4</sub>Br(NHAc).CO.CH<sub>3</sub>. [160°]. Obtained by bromination of acetyl-o-amido-acetophenone in acetic acid solution (Bayer a. Bloem, B. 17, 965). Slender felted colourless needles, sol. hot, sl. sol. cold, alcohol; v. sf. sol. cold water. By KMnO<sub>4</sub> it is oxidised to bromo-isatin [255°]. By boiling with KOH it yields bromo-indigo.

*o*-Tri-bromo-o-amido-acetophenone [52:1] C<sub>6</sub>H<sub>3</sub>Br<sub>3</sub>(NH<sub>2</sub>).CO.CH<sub>3</sub>. [c. 145°]. Fine felted orange yellow needles. V. sol. alcohol and ether, sl. sol. water. Obtained by saponification of the acetyl derivative by boiling it with a mixture of alcohol and aqueous HBr.

*Acetyl derivative*

C<sub>6</sub>H<sub>3</sub>Br<sub>3</sub>(NHAc).CO.CH<sub>3</sub>. [185°], yellowish granular crystals, v. sol. chloroform, sl. sol.

alcohol. Formed by the action of bromine vapour on dry acetyl-*o*-amido-acetophenone mixed with a little iodine. By boiling with HCl it yields *o*-di-chloro-*m*-bromo-*o*-amido-acetophenone. By  $\text{KMnO}_4$  it is oxidised to bromo-isatin. By boiling with dilute NaOH and exposure to the air it gives bromo-indigo (Bayer & Bloem, *B.* 17, 966).

#### DI-BROMO-AMIDO-ANTHRACINONE

$\text{C}_{14}\text{H}_7\text{Br}_2(\text{NH})\text{O}$ . [170° uncorr.]. Prepared by reduction of dibromo-nitro-anthraquinone with stannous chloride (Claus & Diemeltner, *B.* 14, 1834). Slender red needles. Sl. sol. all solvents. Has no basic properties.

#### BROMO-AMIDO-BENZENE v. BROMO-ANILINE.

#### (1, 2, 4)-BROMO-AMIDO-BENZENE SULPHONIC ACID $\text{C}_6\text{H}_3\text{Br}_3\text{SO}_3\text{H}$ , i.e.

$\text{C}_6\text{H}_3\text{Br}_3(\text{NH})\text{SO}_3\text{H}$  (1:2:4). *Bromo-aniline sulphonic acid*. S. 1-19 at 11° (S); 2-61 at 20° (A.); 1-31 at 4° (L.).

**Formation.**—1. By reduction of (1, 2, 4)-bromo-nitro-benzene sulphonic acid (Goslich, *A.* 180, 100).—2. By sulphonation of *o*-bromo-aniline (Andrews, *B.* 13, 2126). 3. From bromo-benzene *p*-sulphonic acid by nitration and reduction. 4. From very dilute aqueous amido-benzene *m*-sulphonic acid and bromine-water (Langfurth, *A.* 191, 176). 5. From (1, 3, 4, 6) di-bromo-*m*-amido-benzene sulphonic acid, fuming HCl, and red P at 150° (Limpricht, *B.* 10, 1542). 6. By heating the same acid with water at 250° (L.).

**Properties.**—Anhydrous needles (from conc. aqueous solution) or four- and six-sided columns containing aq. (from dilute solution). Sl. sol. alcohol. Reduced by HI and P, or by water at 120°, to amido-benzene *m*-sulphonic acid.

**Salts.**— $\text{KAlA}$  aq. (L.).— $\text{KA}$  aq. (Spiegelberg, *A.* 197, 257).— $\text{BaA}$  aq.— $\text{BaA}'_2$  2aq. S. (of  $\text{BaA}'_2$ ) 6-22 at 17°.— $\text{PbA}'_2$  2aq.— $\text{CaA}'_2$  2aq.— $\text{AgA}'_2$  1aq.

(1, 4, 3)-Bromo-amido-benzene sulphonic acid  $\text{C}_6\text{H}_3\text{Br}_3(\text{NH})\text{SO}_3\text{H}$  (1:4:3). S. 47 at 15°.

**Formation.**—1. By heating *p*-bromo-aniline ethyl-sulphate (Nötting, *B.* 8, 1095).—2. By adding bromine to a cold aqueous solution of barium aniline *o*-sulphonate (Limpricht, *A.* 181, 196).—3. By nitration and reduction of bromo-benzene *m*-sulphonic acid (Thomas, *A.* 186, 129). 4. From acetyl-*p*-bromo-aniline and fuming  $\text{H}_2\text{SO}_4$  (Borns, *A.* 187, 368).

**Properties.**—Slender silky needles (containing aq.) or large efflorescent prisms (with 2 aq.). Sl. sol. cold water, v. sl. sol. alcohol. Converted by Br into tri-bromo-aniline. HI and P form aniline *o*-sulphonic acid.

**Salts.**— $\text{NH}_4\text{A}$ .— $\text{KA}$ .— $\text{BaA}$  aq.— $\text{CaA}$  aq.— $\text{PbA}$  2aq.

(1, 4, 2)-Bromo-amido-benzene sulphonic acid  $\text{C}_6\text{H}_3\text{Br}_3(\text{NH})\text{SO}_3\text{H}$  (1:4:2). S. 1-14 at 18°. From bromo-benzene *o*-sulphonic acid by nitration and reduction (Bahlmann, *A.* 181, 203 & 186, 818). Needles (from conc. aqueous solution) or rhombohedra (?) containing 2aq. (from dilute aqueous solution); v. sol. hot water, insol. alcohol and ether. Reduced by HI and P to aniline *m*-sulphonic acid. **Salts.**— $\text{BaA}'_2$  2aq; needles, v. s. sol. water.— $\text{PbA}'_2$ .— $\text{AgA}'_2$ .

#### Bromo-amido-benzene sulphonic acid

$\text{C}_6\text{H}_4\text{Br}(\text{NH})_2(\text{SO}_3\text{H})$  (1:2:2). S. 74 at 8°. Formed in smaller quantity in the preparation

Vol. I.

of the preceding (B.). Prisms; sl. sol. cold water.— $\text{BaA}'_2$  2aq; laminae, v. sol. water.

#### Bromo-amido-benzene sulphonic acid

$\text{C}_6\text{H}_4\text{Br}(\text{NH})_2(\text{SO}_3\text{H})$  (1:3:2). From acetyl-*m*-bromo-aniline and fuming  $\text{H}_2\text{SO}_4$  (Borns, *B.* 8, 1072). Needles.— $\text{BaA}'_2$  2aq.

(1, 2, 3, 5)-Bromo-amido-benzene disulphonic acid  $\text{C}_6\text{H}_2\text{Br}_4(\text{NH})_2(\text{SO}_3\text{H})_2$  (1:2:3:5). Formed by bromination of (1, 2, 4)-amido-benzene disulphonic acid (Zander, *A.* 198, 1). Needles (containing aq.); v. sol. water, sl. sol. alcohol.

**Salts.**—The acid salts are less soluble than the normal ones.— $(\text{NH}_4)_2\text{A}$  2aq.  $\text{BaA}''$  3aq.— $\text{BaH A}''$  5aq.— $\text{PbH A}''$  5aq.  $\text{KA}''$  2aq.

#### Bromo-amido-benzene disulphonic acid

$\text{C}_6\text{H}_3\text{Br}_3(\text{NH})_2(\text{SO}_3\text{H})_2$  (1:4:3:5) or (4:1:3:5) or (2:1:3:5). Formed by adding bromine to an aqueous solution of (1 or 4, 3, 5) amido-benzene disulphonic acid (Heimann, *A.* 188, 179). Prisms (containing 2 aq.); v. s. sol. water.— $\text{BaA}''$  3aq.  $\text{PbA}''$  3aq.

#### Bromo-di-amido-benzene sulphonic acid

$\text{C}_6\text{H}_3\text{Br}_3(\text{NH})_2(\text{SO}_3\text{H})$  (1:2:6:4). *Bromo-m-phenylenediamine sulphonic acid*. S. 51 at 17°. Got by reducing  $\text{C}_6\text{H}_3\text{Br}_3(\text{NO})_2\text{SO}_3\text{H}$  with SnCl<sub>2</sub> (Bassmann, *A.* 191, 244). Long white needles (containing aq.), turns yellow in air. When pure it is sl. sol. water, when impure it is very soluble. Insol. alcohol. Paper moistened with its solution turns red in air. The aqueous solutions of its salts turn blue or red when evaporated. Converted by diazo reaction into *p*-bromo-benzene sulphonic acid.— $\text{BaA}$  aq.

(1, 3, 2, 5) Di-bromo-amido-benzene sulphonic acid  $\text{C}_6\text{H}_3\text{Br}_3(\text{NH})_2(\text{SO}_3\text{H})$  (1:3:2:5). Formed by adding bromine to an aqueous solution of aniline *p*-sulphonic acid (Schmitt, *A.* 120, 138; Lenz, *B.* 8, 1066; *A.* 181, 24). Formed also by brominating (1, 2, 4)-amido-benzene disulphonic acid (Zander, *A.* 198, 16). Needles or prisms (containing 2aq.); v. sol. water and hot alcohol; ppl. by conc.  $\text{H}_2\text{SO}_4$  from its aqueous solution. Br forms tri-bromo-aniline.  $\text{BaA}'_2$  2aq.— $\text{BaA}'_2$  3aq. S. (of  $\text{BaA}'_2$ ) 16 at 11°.  $\text{PbA}'_2$  2aq.— $\text{AgA}'_2$ .

**Reactions.**—HCl forms a product (probably  $\text{C}_6\text{H}_3\text{Br}_3(\text{NH})_2(\text{POCl}_2)(\text{SO}_3\text{H})$ ) from which alcohol produces  $\text{C}_6\text{H}_3\text{Br}_3(\text{SO}_3\text{Cl})(\text{NH})_2(\text{OEt})_2$ . [170°] (Laar, *J. pr.* 128, 256). V. also DI-METHYL-AMIDO-BENZENE SULPHONIC ACID.

(1, 3, 4, 6)-Di-bromo-amido-benzene sulphonic acid  $\text{C}_6\text{H}_3\text{Br}_3(\text{NH})_2(\text{SO}_3\text{H})$  (1:3:4:6). S. 252 at 10°; 219 at 7°; 194 at 4° (Bernsen, *A.* 177, 84; Beckurts, *A.* 181, 213; Reinke, *A.* 186, 286; Knuth, *A.* 186, 301; Langfurth, *A.* 191, 180; Bahlmann, *A.* 191, 229, 234; Spiegelberg, *A.* 197, 246).

**Formation.**—1. From amido-benzene *m*-sulphonic acid and bromine. —2. From (1, 2, 4)-bromo-amido-benzene sulphonic acid and Br.—3. From the corresponding  $\text{C}_6\text{H}_3\text{Br}_3(\text{NO}_2)_2\text{SO}_3\text{H}$ .—4. From (1, 3, 5, 2, 6)-tribromo-nitro-benzene sulphonic acid, Sn, and HCl. —5. From tribromo-amido-benzene sulphonic acid by treating with water at 150°, or by treating with Sn and HCl.

**Properties.**—Needles (from hot water); sl. sol. water, insol. alcohol.

**Reactions.**—1. Water at 250° forms *o*-bromo-aniline sulphonic acid and aniline *m*-sulphonic acid.—2. *Diazo* reaction gives (1, 3, 4)-di-bromo-benzene sulphonic acid. —3. Warmed with

NN

strong alcohol and  $\text{KNO}_3$ , a yellow crystalline body, possibly  $\text{C}_6\text{H}_4\text{Br}_2(\text{SO}_3\text{H})\cdot\text{N}\cdot\text{H}\cdot\text{O}\cdot\text{C}_6\text{H}_4\text{Br}\cdot\text{SO}_3\text{K}$ , is formed. Heated in sealed tubes with alcohol, it splits up into dibromo-benzene sulphonic acid and amido-dibromo-benzene sulphonic acid (Bässmann).

**Salts.**— $\text{BaA}'_2$  6aq. S. (of  $\text{BaA}'_2$ ) 2.99 at  $7^\circ$ ; 8.12 at  $9^\circ$ ; 3.9 at  $23^\circ$ .— $\text{KA}'$  aq.— $\text{NH}_4\text{A}'$ .— $\text{CaA}'_2$  2aq.— $\text{CaA}'_2$  6aq.— $\text{PbA}'_2$  S. 2.9 at  $22.5^\circ$ .

(1,2,4,6)-Di-bromo-amido-benzene sulphonic acid  $\text{C}_6\text{H}_2\text{Br}_4(\text{NH}_2)(\text{SO}_3\text{H})$  [1:2:4:5]. S. 109 at  $10^\circ$ ; 153 at  $24^\circ$ . From (1,2,4)-di-bromo-benzene sulphonic acid by nitration and reduction (Spiegelberg, A. 197, 279). Trimetric tables; v. sl. sol. alcohol.— $\text{NH}_4\text{A}'$  aq.— $\text{KA}'$  2aq.— $\text{BaA}'_2$  aq; S. (of  $\text{BaA}'_2$ ) .67 at  $11^\circ$ .— $\text{PbA}'_2$  aq; S. (of  $\text{PbA}'_2$ ) .11 at  $11^\circ$ .— $\text{CaA}'_2$  3aq.— $\text{CaA}'_2$  4aq.— $\text{AgA}'$  S. .063 at  $11^\circ$ .

(1,3,4,6)-Di-bromo-amido-benzene sulphonic acid  $\text{C}_6\text{H}_2\text{Br}_4(\text{NH}_2)(\text{SO}_3\text{H})$  [1:3:4:5]. S. 3.13 at  $10.5^\circ$ . From amido-benzene *o*-sulphonic acid by bromination (Lamprecht, A. 181, 198; D. 8, 1429), or from (1,3,5)-di-bromo-benzene sulphonic acid by nitration and reduction (Lenz, A. 181, 36). Trimetric tables (anhydrous) or 4-sided prisms (with aq). Converted by Br into tri-bromo-aniline.

**Salts.**  $\text{KA}'$  aq.— $\text{NaA}'$  aq. S. (of  $\text{NaA}'$ ) 3.7 at  $12^\circ$ .— $\text{BaA}'_2$  1½aq. S. (of  $\text{BaA}'_2$ ) .20 at  $11^\circ$ .— $\text{PbA}'_2$  aq.

**Di-bromo-amido-benzene sulphonic acid**  $\text{C}_6\text{H}_3\text{Br}_2(\text{NH}_2)(\text{SO}_3\text{H})$  [1:4:2:6]. S. .62 at  $10.5^\circ$ . From (1,4,2)-di-bromo-benzene sulphonic acid by nitration and reduction (Born, A. 187, 362). Needles or prisms.— $\text{KA}'$ .— $\text{BaA}'_2$  aq.

**Di-bromo-amido-benzene disulphonic acid**  $\text{C}_6\text{H}_2\text{Br}_4(\text{NH}_2)(\text{SO}_3\text{H})_2$  [1:4:3:2:6:7]. From *p*-di-bromo-benzene disulphonic acid by nitration and reduction (Born, A. 187, 367). Crystals; v. sol. water.  $\text{KA}'$ .— $\text{BaA}'_2$ .

**Di-bromo-amido-benzene di-sulphonic acid**  $\text{C}_6\text{H}_2\text{Br}_4(\text{NH}_2)(\text{SO}_3\text{H})_2$  [1:4:6:2:3:5]. From (1,2,4)-amido-benzene disulphonic acid and Br (Heinzelmann, A. 188, 182). Prisms (containing 4aq); v. sol. water.— $(\text{NH}_4)_2\text{A}'_2$ .— $\text{KA}'$ .— $\text{BaA}'_2$  8aq.— $\text{PbA}'_2$  3aq.

**Di-bromo-di-amido-benzene sulphonic acid**  $\text{C}_6\text{H}_2\text{Br}_2(\text{NH}_2)_2(\text{SO}_3\text{H})$  [1:3:2:6:4]. One of the products of the reduction of  $\text{C}_6\text{H}_2\text{Br}_4(\text{NH}_2)_2\text{SO}_3\text{H}$  (Bässmann, A. 191, 214, 218). Tablets (containing aq); v. sl. sol. water.

**Tri-bromo-amido-benzene sulphonic acid**  $\text{C}_6\text{H}_2\text{Br}_3(\text{NH}_2)(\text{SO}_3\text{H})$  [1:3:5:4:6]. S. 13.7 at  $14^\circ$ ; 16.6 at  $7^\circ$  (B).

**Formation.**—1. From amido-benzene *m*-sulphonic acid and  $\text{Br}^4$  (Berndsen, A. 177, 86). 2. From the corresponding nitro-acid, by Sn and HCl, some di-bromo-amido-benzene sulphonic acid being also formed (Renke, A. 186, 282; Knuth, A. 186, 298; Langfurth, A. 191, 198). 3. From (1,2,4)-bromo-amido-benzene sulphonic acid by bromination (Spiegelberg, A. 197, 276).

**Properties.**—Thin needles (containing aq). Sol. cold water and alcohol. Heated with water at  $145^\circ$  it becomes  $\text{C}_6\text{H}_2\text{Br}_2(\text{NH}_2)_2\text{SO}_3\text{H}$ .

**Salts.**— $\text{BaA}'_2$  9aq. S. (dry). .43 at  $7^\circ$  (L). .34 at  $3^\circ$  (Bässmann, A. 191, 221).— $\text{KA}'$  aq. .935 at  $4^\circ$  (B).— $\text{PbA}'_2$  9aq. S. (of  $\text{PbA}'_2$ ) .73 at  $14^\circ$ .

**Tri-bromo-amido-benzene sulphonic acid**  $\text{C}_6\text{H}_2\text{Br}_3(\text{NH}_2)(\text{SO}_3\text{H})$  [1:2:3:4:5]. From (1,2,3,5)-tri-bromo-benzene sulphonic acid by nitration

and reduction (Lenz, A. 181, 48). Tufts of slender needles (containing aq), v. sol. water and 96 p.c. alcohol.— $\text{BaA}'_2$  1½aq.

**Tri-bromo-amido-benzene sulphonic acid**  $\text{C}_6\text{H}_2\text{Br}_3(\text{NH}_2)(\text{SO}_3\text{H})$  [1:2:5:6:4]. From the corresponding nitro-acid (Spiegelberg, A. 197, 288). Long prisms (containing 1½aq) or slender needles (with aq). V. sol. water and alcohol.— $\text{KA}'$  aq. S. (of  $\text{KA}'$ ) 2.09 at  $1^\circ$ .— $\text{NH}_4\text{A}'$ .— $\text{CaA}'_2$  3½aq.— $\text{BaA}'_2$  S. .096 at  $1^\circ$ .— $\text{PbA}'_2$  2aq. S. .40 at  $3.5^\circ$ .— $\text{AgA}'$  ½aq. S. (of  $\text{AgA}'$ ) .46 at  $10^\circ$ .

**Tri-bromo-di-amido-benzene sulphonic acid**  $\text{C}_6\text{H}_2\text{Br}_2(\text{NH}_2)_2\text{SO}_3\text{H}$  [1:3:5:2:4:6]. A product of reduction of  $\text{C}_6\text{H}_2\text{Br}_4(\text{NH}_2)_2\text{SO}_3\text{H}$  (Bässmann, A. 191, 219).— $\text{BaA}'_2$  1½aq.

**Tetra-bromo-amido-benzene sulphonic acid**  $\text{C}_6\text{H}_2\text{Br}_4(\text{NH}_2)(\text{SO}_3\text{H})$  [1:2:3:5:4:6]. S. 2.25 at  $11^\circ$  (Beckurts, A. 181, 223). Got by reducing  $\text{C}_6\text{H}_2\text{Br}_4(\text{NO}_2)(\text{SO}_3\text{H})$  with Sn and HCl, not allowing the temperature to rise to  $100^\circ$ , or Br will be displaced by  $\text{H}_2$ . Needles (containing 2aq). V. sol. alcohol and water.

**Salts.**—(Langfurth, A. 191, 201)  $\text{BaA}'_2$  aq. S. (of  $\text{BaA}'_2$ ) .4 at  $13^\circ$ .— $\text{CaA}'_2$  7aq.  $\text{KA}'$  1½aq. S. (of  $\text{KA}'$ ) 1.71 at  $15^\circ$ .

**Tetra-bromo-amido-benzene sulphonic acid**  $\text{C}_6\text{H}_2\text{Br}_4(\text{NH}_2)(\text{SO}_3\text{H})$  [1:2:3:5:4:6]. S. .03 at  $11^\circ$ . From the nitro acid (Spiegelberg, A. 197, 302). Needles (containing 2aq). V. sol. alcohol.— $\text{KA}'$  aq. S. (of  $\text{KA}'$ ) .106 at  $11^\circ$ .— $\text{CaA}'_2$  2aq. S. (of  $\text{CaA}'_2$ ) .107 at  $11.5^\circ$ .— $\text{BaA}'_2$  aq. S. (of  $\text{BaA}'_2$ ) .0155 at  $11.5^\circ$ .

(a) **BROMO-*o*-AMIDO-BENZOIC ACID**  $\text{C}_6\text{H}_3\text{Br}(\text{NH}_2)\text{CO}_2\text{H}$  [1:2:3]. *Bromo-anthranilic acid*. [170]. From the corresponding nitro-compound by Sn and HCl (Hübner, A. 222, 104; cf. A. 143, 214; 149, 134). Needles; m. sol. water. Sodium amalgam reduces it to *o*-amido-benzoic acid [144]. Nitrous acid forms the diazo-derivative  $\text{C}_6\text{H}_3\text{BrCO}_2\text{H}\cdot\text{N}\cdot\text{N}\cdot\text{H}\cdot\text{C}_6\text{H}_3\text{BrCO}_2\text{H}$ .—**Salts.**— $\text{AgA}'$ .  $\text{BaA}'$  aq.— $\text{CuA}'_2$ .

**Acetyl derivative**  $\text{C}_6\text{H}_3\text{Br}(\text{NHAc})(\text{CO}_2\text{H})$  [17:2:3] [215°]. Obtained by brominating acetyl-*o*-amido-benzoic acid (Jackson, B. 14, 879).

(b) **Bromo-*o*-amido-benzoic acid**. *Bromo-anthranilic acid*.  $\text{C}_6\text{H}_3\text{Br}(\text{NH}_2)\text{CO}_2\text{H}$  [1:4:3]. [208°].

**Formation.**—1. By reducing (1,4,3)-bromo-nitro-benzoic acid (Hübner, Ohly a. Philipp, A. 143, 212; Mecker, Hübner a. Petermann, A. 149, 133). 2. By boiling bromo-isoatic acid with conc. HCl (Dorsch, J. pr. [2] 33, 35).

**Properties.**—V. sol. acetone, sl. alcohol, ether, chloroform, benzene, and glacial acetic acid, sl. sol. boiling water. Sodium-amalgam reduces it to *o*-amido-benzoic acid [144°].

**Salts.**— $\text{BaA}'_2$  4aq; needles, v. sol. water. *Acide.*  $\text{C}_6\text{H}_3\text{Br}(\text{NH}_2)\text{CO}_2\text{NH}_2$  [177°]. From bromo-isoatic acid and  $\text{NH}_3$  aq. Flat needles. V. sol. alcohol, acetone and glacial acetic acid, m. sol. water and benzene. Insol. ether.

(1,2,4)-Bromo-*m*-amido-benzoic acid  $\text{C}_6\text{H}_2\text{Br}_3(\text{NH}_2)\text{CO}_2\text{H}$  [1:2:4]. [225°]. By reducing the nitro-acid by Sn and HCl. Small colourless needles (from water), becomes reddish in air (Hübner, A. 222, 179; Burghard, B. 8, 558; Ravell, B. 10, 1707). Reduced by sodium-amalgam to *m*-amido-benzoic acid.— $\text{HA}\cdot\text{HCl}$ .— $\text{CuA}'_2$ .— $\text{PbA}'_2$ .

(1,3,5)-Bromo-*m*-amido-benzoic acid  $\text{C}_6\text{H}_2\text{Br}_3(\text{NH}_2)\text{CO}_2\text{H}$  [1:3:5]. [215°]. From the

corresponding nitro-acid by Sn and HCl (Hesemann a. Köhler, *A.* 222, 169). Needles (from alcohol). Turns red in light. Salts.—HA'HCl.—(HA')<sub>2</sub>H<sub>2</sub>SO<sub>4</sub>—BaA'<sub>2</sub> 4aq.—CaA'<sub>2</sub> 54aq.

(1,4,2)-Bromo-*m*-amido-benzoic acid  
C<sub>6</sub>H<sub>3</sub>Br(NH<sub>2</sub>)CO<sub>2</sub>H [1:4:2]. (180°). From (1,4,2)-bromo-nitro-benzoic acid, Sn, and glacial HOAc (Burghard, *B.* 8, 560). Flat needles (Smith, *B.* 10, 1706).

(1,2,4,5)-Di-bromo-*o*-amido-benzoic acid  
C<sub>6</sub>H<sub>2</sub>Br<sub>2</sub>(NH<sub>2</sub>)CO<sub>2</sub>H [1:2or6:5:4]. *Di-bromo-anthranilic acid*. [226°–228°].

*Formation*.—1. From di-bromo-nitro-benzoic acid (Smith, *B.* 10, 1706).—2. From *o*-nitro-toluene and bromine at 170° (Wachendorff, *A.* 185, 281; Grieff, *B.* 13, 288).—3. From isatoic acid (*q. v.*) and bromine (Dorsch, *J. pr.* [2] 33, 37).

*Properties*.—Clumps of needles (from alcohol). Long needles (when sublimed). Sol. alcohol, acetone and glacial acetic acid, sl. sol. chloroform, benzene, ether, and water.

*Amide* C<sub>6</sub>H<sub>2</sub>Br<sub>2</sub>(NH<sub>2</sub>)CO.NH<sub>2</sub>. [197°]. Pearly tablets (from alcohol-acetone). Formed from di-bromo-isatoic acid and NH<sub>3</sub>Aq at 100°.

*Di-bromo-*o*-amido-benzoic acid*  
C<sub>6</sub>H<sub>3</sub>Br<sub>2</sub>(NH<sub>2</sub>)CO<sub>2</sub>H [1:2or6:5:4]? *Di-bromo-anthranilic acid*. [225°]. S. 1; S. (alcohol) 2. From the nitro-acid by reduction (Hübner, *A.* 222, 189). Colourless needles. Reduced by sodium amalgam to *o*-amido-benzoic acid.—BaA'<sub>2</sub> 4aq.—CaA'<sub>2</sub> 4aq.—SrA'<sub>2</sub> 2aq.—CuA'<sub>2</sub>. This acid is probably identical with the preceding.

(1,3,4,5)-Di-bromo-*o*-amido-benzoic acid  
C<sub>6</sub>H<sub>2</sub>Br<sub>2</sub>(NH<sub>2</sub>)CO<sub>2</sub>H [1:3:4:5]. *Di-bromo-anthranilic acid*. [225°]. S. 1; S. (HOAc) 3. By reduction of the nitro-acid by Sn and HCl (Hesemann a. Köhler, *A.* 222, 175). Reduced by sodium amalgam to *o*-amido-benzoic acid. Needles (from alcohol).—BaA'<sub>2</sub> 4aq.—CaA'<sub>2</sub> 4aq.—CuA'<sub>2</sub>.

(1,3,5,4)-Di-bromo-*o*-amido-benzoic acid  
C<sub>6</sub>H<sub>2</sub>Br<sub>2</sub>(NH<sub>2</sub>)CO<sub>2</sub>H. *Di-bromo-anthranilic acid*. [196°]. From benzoic acid by bromination, nitration, and reduction (Angerstein, *A.* 158, 16). Needles (from dilute alcohol). Reduced by sodium-amalgam to *o*-amido-benzoic acid.

*Di-bromo-*p*-amido-benzoic acid*  
C<sub>6</sub>H<sub>2</sub>Br<sub>2</sub>(NH<sub>2</sub>)CO<sub>2</sub>H [1:3:2:5]. Obtained by adding bromine-water to an acidified solution of *p*-amido-benzoic acid (Beilstein a. Geitner, *Z.* [2] 1, 505; *A.* 139, 1). Needles (from alcohol).—NH<sub>3</sub>A 2aq.—NaA' 5aq.—CaA' 6aq.—BaA' 4aq.

*Tri-bromo-*o*-amido-benzoic acid*  
C<sub>6</sub>HBr<sub>3</sub>(NH<sub>2</sub>)CO<sub>2</sub>H [1:2:x:4:5]. *Tri-bromo-anthranilic acid*. [c. 119°]. From isatoic acid and bromine (Dorsch, *J. pr.* [2] 33, 37).

*Properties*.—Slender needles. May be sublimed. Very soluble in glacial acetic acid, alcohol and acetone, sol. ether and chloroform, less soluble in benzene, sl. sol. hot water.

*Tri-bromo-*m*-amido-benzoic acid*  
C<sub>6</sub>HBr<sub>3</sub>(NH<sub>2</sub>)CO<sub>2</sub>H [1:3:5:4:6]. [170°]. From *m*-amido-benzoic acid and bromine-water (Beilstein a. Geitner, *Z.* [2] 1, 505; *A.* 139, 6; Vollbrecht, *B.* 10, 1708). Needles; m. sol. hot water. On dry distillation it gives tri-bromo-aniline.—NaA' 4aq.—BaA' 6aq.

*Tri-bromo-di-amido-benzoic acid*  
C<sub>6</sub>Br<sub>2</sub>(NH<sub>2</sub>)<sub>2</sub>(CO<sub>2</sub>H) [1:3:5:2:4:6]. From *s*-di-amido-benzoic acid and bromine-water (Griess,

*A.* 154, 832). Long needles (from dilute alcohol). Sl. sol. cold water.—AgA'.

*Tetra-bromo-*o*-amido-benzoic acid*  
C<sub>6</sub>Br<sub>4</sub>(NH<sub>2</sub>)CO<sub>2</sub>H [1:2:3:4:5:6]. [115°]. From isatoic acid and excess of Br (in glacial acetic acid) (Dorsch, *J. pr.* [2] 33, 38). White needles. At 100° it sublimes in long slender needles.

**BROMO-AMIDO-HYDROCARBOSTYRIL** *v.* p. 164.

**BROMO-AMIDO-HYDROCINNAMIC ACID**  
*v.* **BROMO-AMIDO-β-PHENYL-PROPIONIC ACID**.

**BROMO-AMIDO-NAPHTHALENE** *v.* **BROMO-NAPHTHYLAMINE**.

**BROMO-AMIDO-NAPHTHOIC ANHYDRIDE**

*thostyrl*. [257°]. By reduction of bromo-nitro-(a)-naphthoic acid with FeSO<sub>4</sub> and aqueous NH<sub>3</sub> and ppn. with acetic acid the amido-acid is obtained, and by boiling with alcohol it is converted into the anhydride, which crystallises out on cooling in brown needles (Ekstrand, *B.* 19, 1136).

*Di-bromo-amido-naphthoic anhydride*

Prepared by heating amido-naphthoic anhydride  
C<sub>10</sub>H<sub>4</sub>  suspended in water with a large excess of bromine. Yellow needles (from alcohol). M. sol. hot acetic acid.

*Acetyl derivative* C<sub>11</sub>H<sub>5</sub>ONBrAc [185°]; small yellow needles (Ekstrand, *B.* 19, 1136).

**BROMO-AMIDO-(a)-NAPHTHOQUINONE**

with dilute acids. Orange silky needles. Sublimable. By boiling with dilute alkalis it is converted into bromo-oxy-(a)-naphthoquinone.

*Acetyl derivative*: [137°]; sulphur-yellow needles (Zincke a. Gerland, *B.* 20, 1544).

**BROMO-AMIDO-(a)-NAPHTHOQUINONE**

by adding bromine (5 c.c.) to di-amido-(a)-naphthol or its stannous chloride (10 g.) suspended in acetic acid. Orange-yellow needles (from alcohol). V. sol. hot alcohol and hot benzene. By SnCl<sub>2</sub> it is reduced to bromo-di-amido-(a)-naphthol. By boiling with dilute acids it is converted into bromo-amido-(a)-naphthoquinone

it is converted into bromo-oxy-naphthoquinone-imide C<sub>10</sub>H<sub>4</sub>  . The latter body

when treated with conc. HCl or alcoholic NaOH is converted into bromo-oxy-naphthoquinone

$C_6H_4 \begin{smallmatrix} \diagup CO.C(OH) \\ \diagdown CO.CBr \end{smallmatrix}$  which is also formed by boiling the bromo-amido-naphthoquinone with dilute alkalis (Zincke a. Gerland, *B.* 20, 1510).

**BROMO-O-AMIDO-PHENOL**

$C_6H_4Br(NH_2)(OH)$  [1:3:1]. [128°]. Formed by reducing bromo-nitro-phenol with Sn and HCl (P. Schütt, *J. pr.* [2] 32, 61). Thin plates (from  $CS_2$ ). Needles (from alcohol). Sol. ether, benzene, hot water, and hot chloroform.  $FeCl_3$  turns the aqueous solution cherry-red.

Salts. —  $BHCl$ . Very soluble plates. —  $BHBr$ . Crystallises very easily. —  $BH.SO_4$ .

*Acetyl derivative*  $C_6H_4(OH)(NHAc)Br$ . [178°]. Plates or needles (from water).

*Methyl ether*  $C_6H_4Br(NH_2)(OMe)$ . [98°]. From the nitro-compound, Sn and HCl (Staedel, *A.* 217, 59). Plates (from benzene). V. sol. benzene, ether or hot alcohol, insol. water. Salts. —  $BHCl$ . —  $BH.SO_4$ . —  $BH_2C_2O_4$ .

*Ethyl ether* [57°]. Broad needles (from alcohol). V. sol. benzene, alcohol or ether. Salts. —  $BHCl$ . —  $BH.SO_4$ . —  $BH_2C_2O_4$ .

**Bromo-m-amido-phenol**  $C_6H_4Br(NH_2)OH$  [1:1:3]. *Ethyl ether*  $C_6H_4Br(NH_2)OEt$ . Liquid; v. sol. alcohol and ether, v. sl. sol. water. The hydrochloride, sulphate, and oxalate crystallise in white plates  $C_6H_4Br(OEt)NH_2$ ,  $HCl$ ,  $SnCl_2$  (Lindner, *B.* 18, 612).

**Bromo-p-amido-phenol**  $C_6H_4Br(NH_2)(OH)$  [1:3:6]. [158°]. Prepared by reducing bromo-nitro-phenol, or its benzyl derivative, by Sn and HCl (O. Hölz, *J. pr.* [2] 32, 65). Short needles (from dilute alcohol). Sol. ether, benzene, and chloroform, sl. sol. cold water.

Salts. —  $BHCl$ : silvery plates. —  $(BHCl)SnCl_2$ . —  $BHBr$ .

*Acetyl derivative*  $C_6H_4(OH)(NHAc)Br$ . [167°]. Thick needles (from hot water). Soluble in alkalis.

*Methyl ether*. From the nitro-compound, Sn and HCl (Staedel, *A.* 217, 68). Oil. Insol. water, v. sol. benzene, alcohol, or ether.  $BHCl$ . —  $BH_2H_2SO_4$ . —  $BH_2H_2C_2O_4$ .

*Ethyl ether*. From the nitro-compound, Sn and HCl. Oil.  $BHCl$ . —  $BH_2H_2SO_4$ . —  $BH_2H_2C_2O_4$ .

**Di-bromo-o-amido-phenol**  $C_6H_3Br_2(NH_2)(OH)$  [1:3:5:6]. [92°]. Formed by reducing di-bromo-o-nitrophenol (Hölz, *J. pr.* [2] 32, 69). Slender yellow needles (from dilute alcohol). Sparingly soluble in water, v. sol. alcohol, ether, benzene, and chloroform.

Salts. —  $BHCl$ : plates. —  $(BHCl)_2SnCl_2$ : needles. —  $BHBr$ : needles.

*Acetyl derivative*  $C_6H_3(OH)(NHAc)Br_2$ . [186°]. Yellowish needles (from hot water). Sol. alkalis.

*Methyl ether*  $C_6H_3Br_2(NH_2)(OMe)$ . From the nitro-compound by Sn and HCl (Staedel, *A.* 217, 63). Oil. Sol. alcohol, ether, or dilute acids, insol. cold water, sl. sol. hot water.  $BHCl$ . —  $BH_2H_2SO_4$ . [177°]. —  $BH_2H_2C_2O_4$ .

*Ethyl ether*  $C_6H_3Br_2(NH_2)(OEt)$ . [92°]. Quadratic crystals (from alcohol). V. sol. alcohol or ether. —  $BHCl$ . —  $BH_2H_2SO_4$ . —  $BH_2H_2C_2O_4$ .

**Di-bromo-o-amido-phenol** *Ethyl ether*  $C_6H_3Br_2(NH_2)OEt$  [1:3:4:5:6]?

[53°]. **o-Amido-phenetol**  $C_6H_4(NH_2)OEt$  (10 g.), boiled with glacial acetic acid (100 g.) and bromin (11.7 g.). The product is poured into water and the oil that separates is distilled with steam and recrystallised from alcohol. Glittering prisms grouped in tufts. Resembles di-bromo-o-toluidine in being but feebly basic (Möhlau a. Oehmichen, *J. pr.* 132, 479).

**Di-bromo-m-amido-phenol**

*Ethyl ether*  $C_6H_3Br_2(NH_2)OEt$ . From the nitro-compound. Oil. The hydrochloride, sulphate, and oxalate crystallise in needles. —  $C_6H_3Br_2(OEt)NH_2$ ,  $HCl$ ,  $SnCl_2$ : glistening plates (Lindner, *B.* 18, 613).

**Di-bromo-p-amido-phenol**

$C_6H_3Br_2(NH_2)OH$  [1:3:5:2]. [180°] (M. a. B.); [190°] (L. a. G.). Formed by reducing the nitro-compound (Möhlau, *B.* 16, 2845; Hölz, *J. pr.* [2] 32, 67; Möhlau a. Böhm, *J. pr.* [2] 24, 470; Lellmann a. Grothmann, *B.* 17, 2781). Formed also by reducing di-brominated *p*-diazophenol (*q. v.*) with tin and HCl (Böhmer, *J. pr.* 132, 463):

*Properties*. — Ppd. by  $NaHCO_3$  from solution of its hydrochloride as microscopically small needles grouped in tufts. Turns blue in air. Sl. sol. ether, v. sol. alcohol, m. sol. hot water.

Salts. —  $BHCl$ : glittering plates. —  $(BHCl)SnCl_2$ . —  $BHBr$ .

*Reactions*. — When  $N_2O_5$  is passed into an alcoholic solution of its hydrochloride, yellow crystals of diazo-dibromo-phenol (*q. v.*) are obtained, but this body is isomeric with that by the reduction of which the dibromo-amido-phenol was prepared. An 'intra-molecular change' must therefore have occurred somewhere.

*Acetyl derivative*  $C_6H_3Br_2(NHAc)(OH)$ . [174°]. Glittering plates (from dilute alcohol). *Methyl ether*. From the nitro-compound [127°], Sn, and HCl. White porcelain-like mass. Extremely sol. ether, benzene, or alcohol (Staedel, *A.* 217, 70; Staedel a. Damm, *B.* 11, 1749). Salts. —  $BHCl$ . —  $BH_2H_2SO_4$ . —  $BH_2H_2C_2O_4$ . [193°].

*Ethyl ether* [67°]. Needles (from alcohol). V. sol. alcohol, ether, or benzene. Salts. —  $BHCl$ . —  $BH_2H_2SO_4$ . —  $BH_2H_2C_2O_4$ .

**Tri-bromo-o-amido-phenol**

*Ethyl ether*  $C_6H_2Br_3(NH_2)OEt$  [1:3:4:5:6]? [77°]. From amido-phenetol (5 g.), glacial acetic acid (50 g.) and bromine (17.5 g.). The product is poured into water, and the pp. crystallised from alcohol. Long silky needles. Nearly insol. boiling conc. HCl. It is totally decomposed when heated to a temperature a little above its melting-point.

**Tri-bromo-m-amido-phenol**

$C_6H_2Br_3(NH_2)OH$  [1:3:5:2:6]. [115°]. Formed by reduction of tri-bromo-m-nitro-phenol (Dacowso, *B.* 18, 1168). Colourless silky needles. Sol. alcohol, ether, benzene, and hot, sl. sol. cold, water.  $FeCl_3$  gives a green colouration.

*Ethyl ether*  $C_6H_2Br_3(NH_2)OEt$ . Solid, v. sol. alcohol and ether, sl. sol. water. —  $BHCl$ : white needles, sol. alcohol. —  $BH_2H_2SO_4$ : white needles, sol. alcohol. —  $BHClSnCl_2$ : white needles (Lindner, *B.* 18, 614).

**BROMO-AMIDO-DIPHENYL**

*Acetyl derivative*  $C_{12}H_8BrNHAc$ . [247°]. From Br and *o*-amido-diphenol.

HOAc (Häbner, *A.* 309, 945). Needles (from alcohol).

**Di-bromo-di-amido-diphenyl**  $C_{12}H_8Br_2(NH_2)_2$  [89°]. From di-bromo-di-nitro-diphenyl by Sn and HCl (Fittig, *A.* 132, 207). Insol. water.— $B^2HCl$ .

**Di-bromo-di-amido-diphenyl**  $C_{12}H_8Br_2(NH_2)_2$  [2:4:1]  $C_6H_4Br(NH_2).C_6H_4Br(NH_2)$  [1:2:4]. *Di-bromo-benzidine*. [152°]. Obtained from [3:1]  $C_6H_4Br.NH.NH.C_6H_4Br$  [1:3] and HCl (Gabriel, *B.* 9, 1407). Trimetric crystals, m. sol. cold alcohol.— $B^2HCl$ .— $B^2H.PtCl_4$ .

**Di-bromo-di-amido-diphenyl**  $C_{12}H_8Br_2(NH_2)_2$  [1:5:2]. [108° corr.]. Small plates. Formed by the action of an alcoholic solution of SnCl<sub>4</sub> and H<sub>2</sub>SO<sub>4</sub> on *p*-bromo-benzene-*p*-azo-bromo-benzene. Treated with nitrous acid in alcoholic solution it gives an azimido-body  $C_{12}H_8N_2Br_2$ , which forms glistening violet needles, [206°], sl. sol. alcohol (Schultz, *B.* 17, 465).

**Tetra-bromo-di-amido-diphenyl**  $C_{12}H_8Br_4N_2$ . *Tetra-bromo-benzidine*. [286°]. Prepared by bromination of benzidine (Claus a. Köster, *B.* 14, 86). Slender colourless needles. Sol. alcohol, ether, CS<sub>2</sub>, C<sub>6</sub>H<sub>6</sub>; insol. water and acids.

**BROMO-AMIDO-PHENYL-ACETIC ACID**  $C_8H_7(Br)(NH_2)(CH_2.CO.H)$  [1:2:5]. [136°]. Formed by saponification of the acetyl derivative of its nitrile, or by bromination and saponification of the acetyl derivative of *p*-amido-phenyl-acetic acid (Gabriel, *B.* 15, 840). Colourless plates. Sol. alcohol and ether, insol. CS<sub>2</sub>.

*Acetyl derivative* [165°]. *Nitrile*  $C_8H_7(Br)(NH_2)(CH.CN)$ . *Acetyl derivative*  $C_8H_7(Br)(NHAc)(CH.CN)$  [129°]. Long colourless needles. Sol. alcohol, sl. sol. cold water. Formed by bromination of the acetyl derivative of *p*-amido-phenyl-acetonitrile (Gabriel, *B.* 15, 840).

**Bromo-amido-phenyl-acetic acid**  $C_8H_7Br(NH_2)CH_2.CO.H$  [1:2 or 6:4]. [134°]. From the nitro-compound [114°] by Sn and HCl (P. P. Bedson, *C.* 37, 98). Silky needles (from water). Sol. alcohol and CHCl<sub>3</sub>. Sl. sol. ether.— $B^2HCl$  aq.; turns red in air.

(a) **Bromo-amido-phenyl-acetic acid**  $C_8H_7Br(NH_2)CH_2.CO.H$ . [167°]. From the nitro-acid [169°] by Sn and HCl (Bedson). White needles (from water), reddens in air. Sol. alcohol and chloroform, sl. sol. ether.

*Salt*.— $B^2HCl$  aq.; white needles (from water).

(b) **Bromo-amido-phenyl-acetic acid**  $C_8H_7Br(NH_2)CH_2.CO.H$ . [186°]. From the nitro-acid [162°] by Sn and HCl (Bedson). The hydrochloride is less soluble in water than those of the two preceding bodies.

(1, 3, 2, 5) **Bromo-di-amido-phenyl-acetic acid**  $C_8H_7(Br)(NH_2).CH_2.CO.H$  [1:3:2:5]. [c. 200°]. Long colourless needles. Formed by reduction of (1, 3, 2, 5) **bromo-nitro-amido-phenyl-acetic acid** (Gabriel, *B.* 15, 1995).

**BROMO-AMIDO-PHENYL ETHANE**  $C_8H_7BrN$  i.e.  $C_6H_4Br.CH_2.CH_2.NH_2$ . *Bromo-phenyl-ethyl-amine* (253°). From phenyl-propionamide, KOH aq. and bromine (Hofmann, *B.* 18, 2740). Pearly plates (from water).— $B^2HCl$ .

(1, 2, 5) **BROMO-AMIDO-*s*-PHENYL-PRO-PRIONIC ACID**  $C_8H_7(Br)(NH_2).C_6H_4.CO.H$  [1:2:5]. *Bromo-amido-hydrocinnamic acid* [105°]. Formed by bromination of the acetyl derivative of *p*-amido-phenyl-propionic acid, and

saponification of the product (Gabriel, *B.* 15, 2292). Long glistening crystals. Sol. most ordinary solvents and in acids and alkalis.

*Acetyl derivative*: [160°]. Long colourless needles, soluble in alcohol, ether, and benzene.

**Bromo-*m*-amido-phenyl-propionic acid**  $C_8H_7(Br)(NH_2).C_6H_4.CO.H$  [2:1:5]. [117°–119°]. Long prisms. Sol. water, alcohol, ether, and C<sub>6</sub>H<sub>6</sub>. Prepared by reduction of *p*-bromo-*m*-nitro-hydrocinnamic acid with tin and HCl.— $A^2HCl$ : glistening soluble needles (Gabriel a. Zimmermann, *B.* 13, 1684).

(*rac*) **DI-BROMO-*o*-AMIDO-PHENYL-VALERIC ACID**

$C_{10}H_9Br_2(NH_2).CH_2.CH_2.CH_2.CO.H$ . [96°]. with aq. Long colourless needles (containing aq.). Formed by reduction of an alcoholic solution of di-bromo-amido-phenyl-di-bromo-valeric acid  $C_{10}H_9Br_2(NH_2).CHBr.CHBr.CH_2.CH_2.CO.H$  with zinc and HCl. V. sol. ordinary solvents, insol. cold water. It could not be converted into an inner anhydride, even by dehydrating agents.

*Ethyl ether*  $C_{10}H_9Br_2(NH_2)(CO_2Et)$ ; thick oil; its hydrochloride forms white needles [136°]. *Acetyl derivative*  $C_{10}H_9Br_2(NHAc)(CO_2H)$  [206°]; aggregates of thin white needles; v. sol. alcohol, ether, &c.

*Acetyl-ethyl ether*  $C_{10}H_9Br_2(NHAc)(CO_2Et)$  [139°]; colourless crystals; v. sol. alcohol, ether, and acetic acid, more sparingly in benzene, insol. water and ligroin; in small quantities it can be distilled undecomposed (Dichl a. Einhorn, *B.* 20, 380).

(*rac*) **Tetra-bromo-*o*-amido-phenyl-valeric acid**  $C_{10}H_9Br_4(NH_2).CHBr.CHBr.CH_2.CH_2.CO.H$ . [167°]. Formed by bromination of *o*-amido-styryl-propionic acid dissolved in chloroform. Small microscopic needles. V. sol. alcohol, ether, and acetic acid, insol. water and CS<sub>2</sub>. (Dichl a. Einhorn, *B.* 20, 379).

**BROMO-*o*-AMIDO-QUINOLINE**

$C_8H_6N(Br)(NH_2)$ . [164°]. Large monoclinic prisms, or long colourless needles (containing aq.). Sol. alcohol and ether.

*Salts*.— $B^2HNO_3$ : glistening yellow needles. — $B^2HCl$ : soluble red prisms. — $B^2H_2Cl_4PtCl_4$ : microscopic orange needles.

*Acetyl derivative*  $C_8H_6N(Br)(NHAc)$ . [105°]. Thin colourless plates (La Coste, *B.* 15, 1920).

**DI-BROMO-AMIDO-RESORCIN**

$C_6H_3Br_2(NH_2)(OH)_2$  [1:2:3]. *Di-ethyl ether*  $C_6H_3Br_2(NH_2)(OEt)_2$  [112°]; glistening needles or plates (Will a. Pakull, *B.* 20, 1126).

**BROMO-AMIDO-STYRENE**

$C_8H_7Br(NH_2).C_6H_5$ . *Acetyl derivative* [183°]; felted needles, sol. alcohol, ether, and acetic acid; formed by bromination of *p*-amido-cinnamic acid dissolved in AcOH (Gabriel a. Liezberg, *B.* 16, 2043).

**BROMO-AMIDO-SUCCINIC ACID**

$C_8H_7Br(NH_2)(CO_2H)_2$  [140°]. From di-bromo-succinic acid and alcoholic NH<sub>3</sub> (Claus, *B.* 15, 1850). Radiating needles; v. sol. water and alcohol.— $Ag^2A$ .

**BROMO-AMIDO-THYMOL**

$C_8H_7Br.MePr(NH_2)(OH)$ . Prepared by adding Na<sub>2</sub>CO<sub>3</sub> to dilute solution of its hydrobromide (*infra*). Long colourless prisms, rapidly turning deep violet.

moderately strong HBr to thymoquinone-chloroimide (q. v.) a yellow flocculent pp. is formed. Ether extracts bromo-thymoquinones from this, leaving the above salt, which is soluble in water and alcohol, but is thrown down as needles when HBr is added to its concentrated aqueous solution (Andresen, *J. pr.* 131, 182).

**Bromo-amido-thymol** (c. 90%). From bromo-nitro-thymol, zinc-dust, and HCl (Mazzara & Discalzo, *G.* 16, 196). Scales. Converted by nitrous acid gas into bromo-thymoquinone [48°].

**BROMO-AMIDO-TOLUENE** v. **BROMO-TOLUIDINE**.

**Bromo-di-amido-toluene** v. **BROMO-TOLYLENE DIAMINE**.

**BROMO-AMIDO-TOLUENE SULPHONIC ACID**  $C_6H_4Me(CH_2)(NH_2)BrSO_3H$  [1:2:3:5]. *Bromo-toluidine sulphonic acid*. From *o*-toluidine sulphonic acid and bromine-water (Neville & Winther, *C. J.* 37, 627). Prisms.

*Reactions.* 1. Converted by diazo-reaction into a bromo-toluene sulphonic acid whose sulphochloride melts at 56° and whose amide at 147°. 2. Heated with HCl at 160° it gives dibromo-*o*-toluidine [41°] and two mono-bromo-toluidines, an oil and a crystalline body, [54°-57°]. One of these bromo-toluidines must be obtained from the acid by displacement of  $SO_3H$  by  $H$ , and must subsequently give rise to the other mono- and the di-bromo-toluidine. Inasmuch as oily bromo-toluidine,  $C_6H_4Me(NH_2)Br$  [1:2:3], heated with HCl at 160° gives a substance [40°-47°] and crystals [53°-55°], while the crystalline bromo-toluidine [54°-57°] is not affected by this treatment, we must suppose the sulphonic acid to be  $C_6H_4(CH_2)(NH_2)BrSO_3H$  [1:2:3:5] rather than [1:2:5:3]. When it is heated with HCl the oily bromo-toluidine is first formed, but this being unstable changes into its crystalline isomeric and the crystalline dibromo-toluidine.

**Bromo-amido toluene sulphonic acid**  $C_6H_4Me(NH_2)Br(SO_3H)$  [1:4:2:3 or 5]. S. 532 at 21°. From *o* bromo toluene by sulphonation, nitration, and reduction (Schäfer, *A.* 174, 360). Trimetric laminae (from hot water) or nodules (from alcohol). Converted by bromine-water into tri-bromo-toluidine [82°].

Salts.  $BaA'_2$  aq.  $PbA'_2$  aq.

**Bromo-amido-toluene sulphonic acid**  $C_6H_4Me(NH_2)Br(SO_3H)$  [1:5:3:4:3]. From (1,4,2)-bromo-toluene sulphonic acid by nitration and reduction (S.). Needles (from water). V. sl. sol. water.  $-BaA'_2$  aq.

**Bromo-amido-toluene sulphonic acid**

$C_6H_4Me(NH_2)Br(SO_3H)$  [1:2:4:6]. S. 3-2. From (1,4,3)-bromo toluene sulphonic acid by nitration and reduction (Schäfer, *A.* 174, 360). Prisms (from water). Bromine-water gives tri-bromo-toluidine [72°].  $-BaA'_2$  2aq.  $-NaA'_2$  2aq.

**Bromo-amido toluene sulphonic acid**

$C_6H_4Me(NH_2)Br(SO_3H)$  [1:4:2:2]. S. 23 at 20°. From boiling aqueous *p*-toluidine *o*-sulphonic acid and bromine (Jensen, *A.* 172, 230; *B.* 7, 65). Needles (from water). V. sl. sol. boiling water.  $-KA'$  aq.  $-BaA'_2$  7aq.

**Bromo-amido-toluene sulphonic acid**

$C_6H_4Me(NH_2)Br(SO_3H)$ . S. 19 at 20°. From *o*-toluidine sulphonic acid by conversion into *o*-bromo toluene sulphonic acid, nitration, and re-

duction (Pagel, *A.* 176, 800). Minute thin prisms.  $-BaA'_2$  aq.

**Bromo-amido-toluene sulphonic acid**

$C_6H_4Me(NH_2)Br(SO_3H)$  [1:4:5:3]. Formed, together with di-bromotoluidine, by passing bromine-vapour into cold aqueous *p*-toluidine *m*-sulphonic acid (v. Pechmann, *A.* 173, 210; Limpricht, *B.* 7, 452). Clumps of needles. V. e. sol. water. Converted by diazo-reaction into (3 or 5, 1, 2) bromo-toluene sulphonic acid.  $-KA'$ .  $-BaA'_2$  2aq.  $-PbA'_2$ .  $-AgA'$ .

**Di-bromo-*o*-amido-toluene sulphonic acid**

$C_6H_4Me(NH_2)Br_2SO_3H$  [1:2:3:7:4]. S. 64 at 13-5°. From *o*-toluidine *p*-sulphonic acid  $C_6H_4Me(NH_2)(SO_3H)$  [1:2:4] and bromine (Hayduck, *B.* 7, 1353; *A.* 172, 211). Capillary needles containing aq (from water).  $-BaA'_2$  9aq.

**Di-bromo-amido-toluene sulphonic acid**

$C_6H_4Me(NH_2)Br_2(SO_3H)$  [1:2:3:7:5:7]. From *o*-toluidine by sulphonation and bromination. Needles (containing aq). V. sol. hot water and hot alcohol. Gives tri-bromo-toluidine [112°] when distilled with KOH.  $-BaA'_2$  4aq.  $-PbA'_2$  3aq (Gerver, *A.* 169, 380).

**Bromo-di-amido-toluene sulphonic acid**

$C_6H_4Me(NH_2)_2BrSO_3H$  [1:2:7:6:3:4]. From toluene *p*-sulphonic acid by nitration and reduction (Schwanert, *A.* 186, 360). Tables; sl. sol. water.  $-KA'$  2aq.

**DI-BROMO-AMYL ALCOHOL**  $C_5H_{11}Br_2O$  i.e.  $CH_3Br.CHBr.CHBr.OH$ . *Di-bromo-di-ethyl-carbinol*. From vinyl-di-ethyl-carbinol and bromine (Wagner, *J. R.* 16, 320). Non-volatile liquid.

**BROMO-*o*-AMYL-ANTHRACENE**

$C_{10}H_7Br$  i.e.  $C_6H_4 \begin{array}{c} \diagup C(C_2H_5) \\ | \\ CBr \end{array} C_2H_5$  [76°]. Yellow needles. Fluorescent. Prepared by bromination of amyl-anthracene in  $CS_2$ .

*Picric acid compound*. [110°]. Orange-yellow needles (Liebermann, Tobias, *B.* 14, 797).

**BROMO-*sec*-AMYL-BENZENE**  $C_{11}H_{15}Br$  i.e.

$C_6H_5.CHBr.CHBr.CH_2(2)$ . (c. 79°) at 40 mm. S.G. 21 1.28. Oil. Obtained by brominating *sec*-amyl-benzene (Daferet, *M.* 4, 620). Decomposed slowly by boiling water into HBr and pentenyl-benzene.

**$\gamma$ -3-di-bromo-amyl-benzene** [53°-54°]

$Ph.CHBr.CHBr.CH_2.CH_2.CH_3$ . From phenyl-amylene (q. v.) and bromine. Needles or plates.

**$\gamma$ -3-di-bromo-isoamyl-benzene**

$Ph.CHBr.CHBr.CH(CH_3)_2$ . [128°-129°]. From phenyl-iso-amylene and Br (Schraumm, *A.* 218, 391). Needles (from alcohol).

**Tri-bromo-isoamyl-benzene**  $C_{11}H_{13}Br_3$ . [140°].

Obtained by brominating iso-amyl-benzene at 100° (Bigot & Fittig, *A.* 141, 151). Needles.

**BROMO-ISOAMYLENE**  $C_{10}H_{17}Br$ . *Pentenyl-*

*bromide*. (100°-110°). From 'isoamylene' by successive treatment with bromine and alcoholic KOH (Bauer, *A.* 120, 167). Successive treatment with conc.  $H_2SO_4$  and water forms amylene dibromide and a ketone  $C_{10}H_{18}O$  (Bouchardat, *C. R.* 93, 316).

**$\alpha$ -Bromo-iso-amylene** (111°)  $Pr.CH:CHBr$ .

From isovaleric aldehyde by successive treatment with  $PCl_5$  and alcoholic KOH (Bruylants, *B.* 8, 406).

**$\gamma$ -Bromo-*n*-amylene**  $CH_3.CBr.CH_2.CH_2.CH_3$ . [123°]. S.G. 21 1.10. From methyl propyl ketone

by successive treatment with  $\text{PCl}_5\text{Br}_2$  and alcoholic KOH (B.).

**Bromo-amylenes**  $\text{C}_6\text{H}_4\text{Br}_2$ . (111°). From di-bromo-hexaol acid  $\text{CH}_2\text{CHBr.CBrEt.CO}_2\text{H}$  and cold aqueous  $\text{Na}_2\text{CO}_3$  (Fittig, *A.* 200, 36).

**Bromo-amylenes**  $\text{C}_6\text{H}_4\text{Br}_2$ . (115°). From isovalerylene and HBr (Reboul, *Z.* 1867, 173).

**Bromo-amylenes**  $\text{C}_6\text{H}_4\text{Br}_2$ . (c. 106°). S.G. 1.5178. From isoprene  $\text{C}_5\text{H}_8$  and HBr (Bouchardat, *J.* 1879, 577).

**Di-bromo-amylenes**  $\text{C}_6\text{H}_3\text{Br}_3$ . (c. 170°). From isovalerylene and bromine (Reboul, *A.* 135, 372).

**Di-bromo-amylenes**  $\text{C}_6\text{H}_3\text{Br}_3$ , i.e.  $\text{Pr.CBr.CHBr}$ . (175°). From isopropyl-acetylene and Br (Bruylants, *B.* 8, 407).

**Di-bromo-amylenes**  $\text{C}_6\text{H}_3\text{Br}_3$ , i.e.  $\text{Pr.CBr.CHBr}$ . (190°). From *n*-propyl-acetylene and Br (B.).

**BROMO-AMYLENE GLYCOL**  $\text{C}_6\text{H}_4\text{Br}_2(\text{OH})_2$ . From amylenes dibromide by successive treatment with  $\text{AgOAc}$  and solid KOH (Bauer, *J.* 1861, 664).

#### TRI-BROMO-*p*-ISOAMYL-TOLUENE

$\text{C}_{10}\text{H}_{13}\text{Br}_3$ , i.e.  $\text{C}_6\text{H}_4\text{Br}_3\text{CH}_2\text{CH}_2\text{CH}_3$ . From *p*-isoamyl-toluene and bromine at 100°. Sticky liquid (Bigot a. Fittig, *A.* 141, 135).

**TRI-BROMO-ANETHOL**  $\text{C}_{10}\text{H}_7\text{Br}_3\text{O}$ . From anethol and Br. Crystals (Cahours, *A.* 41, 60).

**BROMO-ANILIC ACID** v. DI-BROMO-*o*-OXYQUINONE.

#### *o*-BROMO-ANILINE $\text{C}_6\text{H}_4\text{BrNH}_2$ i.e.

$\text{C}_6\text{H}_4\text{Br}(\text{NH}_2)$  (122). Mol. w. 172. (31°). (229° i. v.). From *o*-bromo-nitro-benzene by reduction with tin and HCl (Fittig a. Mager, *B.* 7, 1175).

**Acetyl derivative**  $\text{C}_6\text{H}_4\text{BrNHAc}$ . *o*-Bromo-acetanilide. (99°). Long needles (Körner, *G.* 4, 330).

***m*-Bromo-aniline**  $\text{C}_6\text{H}_4\text{Br}(\text{NH}_2)$  (133). (189°). (251°). **Formation.**—1. From *m*-bromo-nitro-benzene (Fittig a. Mager, *B.* 8, 361).—2. *m*-Nitro-diazo-benzene sulphate (from *m*-nitroaniline) is treated with a hot solution of cuprous bromide and the crude *m*-bromo-nitro-benzene reduced with tin and HCl (Sandmeyer, *B.* 18, 1495).

**Acetyl derivative**  $\text{C}_6\text{H}_4\text{BrNHAc}$ . (88°). Needles (from dilute alcohol) (Scheutelen, *A.* 231, 175).

***p*-Bromo-aniline**  $\text{C}_6\text{H}_4\text{Br}(\text{NH}_2)$  (144). (62°). (Mills, *P. M.* [5] 14, 27). (66°) (Körner, *J.* 1875, 342).

**Formation.**—1. By reducing *p*-bromo-nitro-benzene with tin and HCl (Riche a. Bérard, *A.* 133, 52; Fittig a. Mager, *B.* 7, 1175; 8, 361).—2. By bromination of acetanilide and distillation of the product with KOH (Mills, *P. M.* [4] 19, 21; *Pr.* 10, 589).—3. By distilling bromoisatin with KOH (Hofmann, *A.* 53, 42).—4. In small quantity by brominating aniline with Br vapour or in benzene solution (Kekulé, *Z.* 1866, 387).

**Properties.**—Trimetric crystals; insol. cold water, v. sol. alcohol and ether. Decomposed on boiling, giving aniline, and di- and tri-bromo-aniline.

**Reactions.**—1. HCl at 160° gives aniline and di-bromo-aniline (Fittig a. Buchner, *A.* 188, 23). 1. Sodium acts on it in ethereal solution forming benzene-azo-benzene, aniline, and NaBr (Anschütz a. Schultz, *B.* 9, 1398; Claus a. Loques, *B.* 16, 909).—2. By dissolving in cooled aqueous  $\text{HNO}_3$  it is converted into tri-nitro-aniline (pietamide) (Hager, *B.* 18, 2578).—4. By nitra-

tion of *p*-bromaniline dissolved in 10 pts. of  $\text{H}_2\text{SO}_4$  bromo-nitro-aniline  $\text{C}_6\text{H}_3\text{Br}(\text{NO}_2)(\text{NH}_2)$  (4:3:1) is produced (Nöling a. Collin, *B.* 17, 266).—5. Cyanogen forms a compound  $\text{C}_6\text{H}_4\text{Br.NHC}(\text{CN})_2$  (NH). $\text{C}(\text{NH})_2\text{NHC}(\text{CN})_2$  (245°); white plates (from alcohol) (Sant, *J. pr.* [2] 55, 530).

**Salts.**— $\text{B}^+\text{HCl}$ : monoclinic. — $\text{B}^+\text{H}_2\text{PbCl}_2$ . — $\text{B}^+\text{HBr}$  aq: monoclinic prisms (Staedel, *B.* 16, 28). — $\text{B}^+\text{H}_2\text{SO}_4$ : laminae. — $\text{B}^+\text{H}_2\text{CO}_3$ .

**Formyl derivative**  $\text{C}_6\text{H}_4\text{Br.NH}(\text{CO.H})$ . (119°). Long white needles. Insol. cold water, sl. sol. hot water, v. sol. alcohol and ether. Prepared by heating *p*-bromaniline with formic ether, or by brominating formanilide (Dennstedt, *B.* 13, 234).

#### Thioformyl derivative

$\text{C}_6\text{H}_4\text{Br.NH}(\text{CS.H})$  (190°). Needles. V. sol. hot ether and alcohol. Prepared by the action of  $\text{P}_2\text{S}_5$  on the preceding body (Dennstedt, *B.* 13, 236).

**Acetyl derivative** (166°). From acetanilide in glacial  $\text{HOAc}$  and Br (Remmers, *B.* 7, 346; Gürke, *B.* 8, 1114). Also from *p*-bromo-aniline and  $\text{AcCl}$  (Körner, *G.* 4, 329), or acetamide (Kelbe, *B.* 16, 1200). Monoclinic prisms;  $a:b:c = 1.538:1:1.435$  (Pancbianco, *G.* 9, 357). M. sol. alcohol, v. sl. sol. water.

#### Isobutyryl derivative

$\text{C}_6\text{H}_4\text{Br.NH.C}_4\text{H}_9\text{O}$  (128°). From isobutyryl-aniline and Br vapour (Norton, *Am.* 7, 117). Needles (from alcohol).

#### Benzoyl derivative $\text{C}_6\text{H}_4\text{Br}(\text{NHBr}_2)$

(202°). From benzanilide and Br (Meinecke, *B.* 8, 564).

#### Oxalyl derivative $\text{C}_6\text{O}_4\text{NH.C}_6\text{H}_4\text{Br}$

(above 200°). From Br and oxalide in  $\text{HOAc}$  (Dyer a. Mixer, *Am.* 8, 351).

#### Di-bromo-aniline $\text{C}_6\text{H}_3\text{Br}_2(\text{NH}_2)$ (133:4). (70°).

**Formation.**—1. By acetylating dibrominated acetanilide (Griess, *A.* 121, 266), or brominated *o*- or *p*-L.o.ac-acetanilide (Körner, *G.* 4, 329).—2. Together with mono- and tri-bromo-aniline by brominating aniline (Kekulé, *K.* 2, 635).—3. By distilling di-bromo-isatin with KOH (Hofmann, *A.* 53, 47).—4. Together with mono- and tri-bromo-aniline by heating nitrobenzene with conc.  $\text{HBrAq}$  at 190° (Baumbauer, *B.* 2, 122; *Z.* [2] 5, 198).—5. By reducing di-bromo-nitro-benzene (Wurster, *B.* 6, 1491).

#### Properties.—Needles or long plates.

**Salts.**— $\text{B}^+\text{HCl}$ . — $\text{B}^+\text{H}_2\text{PbCl}_2$ . — $\text{B}^+\text{H}_2\text{SO}_4$ .

#### Acetyl derivative $\text{C}_6\text{H}_3\text{Br}_2\text{NHAc}$ (146°).

**Benzoyl derivative**  $\text{C}_6\text{H}_3\text{Br}_2\text{NHBr}_2$  (133:4)? (131°). From benzanilide and Br (Hübner, *B.* 10, 1710).

#### *s*-di-bromo-aniline $\text{C}_6\text{H}_3\text{Br}_2(\text{NH}_2)$ (13:5).

(57°). From *p*-nitro acetanilide, by successive conversion into nitro-aniline, di-bromo-nitro-aniline, and di-bromo-nitro-benzene, and reduction of the product (Körner, *G.* 4, 368; Janger, *A.* 215, 116). Needles.

#### Di-bromo-aniline $\text{C}_6\text{H}_3\text{Br}_2(\text{NH}_2)$ (12:4).

(80°). From the corresponding di-bromo-nitro-benzene (58°) (Körner, *G.* 4, 370).

#### Di-bromo-aniline $\text{C}_6\text{H}_3\text{Br}_2(\text{NH}_2)$ (14:3).

(52°). From the corresponding nitro-compound (85°) (Riche a. Bérard, *C. R.* 69, 141; Meyer a. Stuber, *A.* 165, 180).

#### Tri-bromo-aniline $\text{C}_6\text{H}_2\text{Br}_3(\text{NH}_2)$ (13:5:6).

(119°). (306°).

aniline or on an aqueous solution of a salt of aniline (Fritzsche, *A.* 44, 291; *J. pr.* 28, 204; Hofmann, *A.* 53, 50).—2. By the action of Br on *o*- or *p*-bromo-aniline (Körner, *G.* 4, 305).—3. By reduction of tri-bromo-nitro-benzene (K.). 4. Together with aniline and di-bromo-aniline by the dry distillation of *p*-bromo-aniline or by heating it with HClAq at 160° (Buchner, *Z.* 8, 861).

**Preparation.**—Bromine (500 g.) is gradually added to aniline (100 g.); as soon as a solid mass is formed glacial acetic acid is added and the addition of bromine continued until the mass has a red colour. The product is washed with dilute alcohol and water and crystallised from alcohol (H. Silberstein, *J. pr.* [2] 27, 101). Yield 80 per cent.

**Properties.**—Long colourless needles.

**Reactions.**—1. N<sub>2</sub>O<sub>5</sub> passed into tri-bromo-aniline half dissolved, half suspended in alcohol, gives a yellow pp. of tribromo-diazo-benzene nitrate.—2. Converted by diazo-reactions into *o*-tri-bromo-benzene and into *u*-tetra-bromo-benzene.—3. Conc. HNO<sub>3</sub> gives di-bromo-di-nitro-methane, tetra-bromo quinone, *u*-tetra-bromo-benzene, picric acid, and oxalic acid (Losanitsch, *B.* 15, 472).

**Salts.** The salts are very unstable, and cannot be formed in aqueous solution. BrHBr: small white needles (190°), insol. ether and benzene; decomposed by water.—BrHCl: small white needles (Gattermann, *B.* 16, 635).

**Acetyl derivative** C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>NIHAc. [232°] (Remmers, *B.* 7, 349).

**Diacetyl derivative** C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>NAc<sub>2</sub>. [123°].

**Tri-bromo-aniline** C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>(NH<sub>2</sub>) [123.5°]. [above 130°]. From tri-bromo-nitro-benzene [112°] (Körner, *G.* 4, 325). Its salts are not decomposed by water.

**Tetra-bromo-aniline** C<sub>6</sub>HBr<sub>4</sub>(NH<sub>2</sub>) [123.5-6°]. [115°]. Formed by brominating *m*-bromo-aniline, or (1, 4, 3)-di-bromo-aniline (Körner, *G.* 4, 328; Wurster a. Nötling, *B.* 7, 1564). Is a by-product in the action of bromine on nitro-benzene in presence of FeBr<sub>3</sub> (Schenfelen, *A.* 231, 161). Needles. Converted by the diazo-reaction into *u*-tetra-bromo-benzene.

**Penta-bromo-aniline** C<sub>6</sub>Br<sub>5</sub>NH<sub>2</sub>. [222°]. Obtained by brominating (1, 3, 5)-di-bromo-aniline (Körner, *G.* 4, 368). Large needles (from alcohol mixed with toluene).

**BROMO-ANILINE SULPHONIC ACID** *v.* BROMO-AMIDO-BENZENE SULPHONIC ACID.

**BROMO-ANISIC ACID** *v.* Methyl derivative of BROMO-OXY-BENZOIC ACID.

**BROMO-ANISIDINE** *v.* Methyl-Bromo-AMIDO-PHENOL.

**BROMO-ANTHRACENE** C<sub>14</sub>H<sub>8</sub>Br<sub>2</sub>. [100°]. Obtained by warming anthracene dibromide. Needles. Forms a red picric acid compound.

(A. 1, 2)-Di-bromo-anthracene C<sub>14</sub>H<sub>6</sub>Br<sub>2</sub>. [221°]. From Br and anthracene in CS<sub>2</sub> (Graebe a. Liebermann, *A. Suppl.* 7, 273). From triphenyl-methane in CS<sub>2</sub> and bromine in sunlight (triphenyl-methyl bromide being also formed) (Allen a. Kölliker, *A.* 227, 109; 228, 251). Golden needles (from toluene); may be sublimed. *V. sl. sol.* alcohol and ether. Alcoholic KOH at 100° forms anthracene. Dilute HNO<sub>3</sub> gives anthra-

quinone. The compound with picric acid is red. Combines with Br forming C<sub>14</sub>H<sub>4</sub>Br<sub>4</sub>, [170°-180° decomposed at 180° into tri-bromo-anthracene HBr, and Br.

**Di-bromo-anthracene** C<sub>14</sub>H<sub>8</sub>Br<sub>2</sub> [B. 1, 2]? [192°]. From di-bromo-anthraquinone, HI, and P at 150° (Miller, *A.* 182, 367). Golden tables (from alcohol). Oxidises to di-bromo-anthraquinone.

**Tri-bromo-anthracene** C<sub>14</sub>H<sub>6</sub>Br<sub>3</sub>. (A. 1, 2, B.) [169°]. Formed by heating (A. 1, 2)-di-bromo-anthracene tetrabromide (G. a. L.). Yellow needles (from benzene). Oxidised by HNO<sub>3</sub> to bromo-anthraquinone (Claus a. Hertel, *B.* 14, 979).—Bromide: C<sub>14</sub>H<sub>5</sub>Br<sub>3</sub>.

**Tetra-bromo-anthracene** C<sub>14</sub>H<sub>4</sub>Br<sub>4</sub> (A. 1, 2, B. 1, 2)? [254°]. From di-bromo-anthracene tetrabromide and alcoholic KOH (Anderson, *A.* 122, 304; G. a. L.). Yellow needles (from xylene). Gives di-bromo-anthraquinone on oxidation.—Bromide: C<sub>14</sub>H<sub>3</sub>Br<sub>4</sub>. [212°] (Hammerschlag, *B.* 10, 1212).

**Penta-bromo-anthracene** C<sub>14</sub>H<sub>2</sub>Br<sub>5</sub>. [212°]. Formed by heating tetra-bromo-anthracene tetrabromide at 230° (II). Yellow powder. Oxidises to tetra-bromo-anthraquinone.

**Hexa-bromo-anthracene** C<sub>14</sub>HBr<sub>6</sub>. [310°-320°]. Prepared by the action of Br in presence of 1 on di-bromo-anthracene (Diehl, *B.* 11, 178). Oxidised by K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and H<sub>2</sub>SO<sub>4</sub> to tetra-bromo-anthraquinone [c. 300°].

**Hexa-bromo-anthracene** C<sub>14</sub>H<sub>2</sub>Br<sub>6</sub>. [above 370°]. From C<sub>14</sub>H<sub>2</sub>Br<sub>5</sub> and alcoholic NaOH (H.). Silky yellow needles (from kerosene). Oxidation gives tetra-bromo-anthraquinone [above 370°].

**Hepta-bromo-anthracene** C<sub>14</sub>HBr<sub>7</sub>. [above 350°]. Prepared by the prolonged action of Br at 200° in presence of 1 on di-bromo-anthracene (D.). Yellow needles. Insol. alcohol and ether.

**Octo-bromo-anthracene** C<sub>14</sub>HBr<sub>8</sub>. Formed by very prolonged action of iodine bromide at 360° on hepta-bromo-anthracene (D.). Needles. Insol. most ordinary solvents, *sl. sol.* nitro-benzene and aniline.

(A. 1)-BROMO-ANTHRACENE-(A. 2)-CARBOXYLIC ACID C<sub>14</sub>H<sub>5</sub>Br(COOH)C<sub>6</sub>H<sub>4</sub>. [266°].

Formed by the action of bromine upon anthracene-(A.)-carboxylic acid in acetic acid. Long glistening yellow needles. Sublimable. *Sol.* alcohol, ether, and acetic acid, *v. sl. sol.* benzene and water. Its solutions have a blue fluorescence. Evolves CO<sub>2</sub> at its melting-point leaving bromo-anthracene.

**Salts.**—AgA': yellow microscopic prisms.—KA': long very slender yellow needles.—BaA<sub>2</sub>: yellowish needles (Behla, *B.* 20, 704).

**DI-BROMO-ANTHRACENE DISULPHONIC ACID** C<sub>14</sub>H<sub>6</sub>Br<sub>2</sub>(SO<sub>3</sub>H)<sub>2</sub>. From di-bromo-anthracene and fuming H<sub>2</sub>SO<sub>4</sub> (Perkin, *J.* 24, 19). Oxidises to anthraquinone disulphonic acid.

**Salts.**—NaA'.—BaA'.

**BROMO-ANTHRANOL** C<sub>14</sub>H<sub>9</sub>OBr *ide.*

C<sub>14</sub>H<sub>8</sub>Br(COOH)C<sub>6</sub>H<sub>4</sub> or C<sub>14</sub>H<sub>8</sub>Br(CO)C<sub>6</sub>H<sub>4</sub>.

[148°-151°]. Formed by the action of (1 mol. of) bromine upon anthranol (1 mol.) dissolved in CS<sub>2</sub>. Yellowish crystals. Insol. boiling aqueous, but converted by cold alcoholic KOH into an orange K salt (Goldmann, *B.* 20, 2437).

# BROMO-BARBITURIC ACID.

581

**Di-bromo-anthranol**  $C_8H_4OBr_2$ , *q.*

$O_6H_2 \begin{smallmatrix} CO \\ \diagup \diagdown \\ CBr \end{smallmatrix} O_6H_2$ . **Anthraquinone-bromide**.

[1877]. Formed by the action of (rather more than 2 mol. of) bromine upon anthranol (1 mol.) dissolved in  $CS_2$ . Large rhombic crystals. Insol. aqueous alkalis. By boiling with acetic acid it is readily converted into anthraquinone.

(B. 1)-**BROMO-ANTHRAQUINONE**

$C_{14}H_8BrO_2$ . [1887]. Yellow needles. Sublimable. Prepared by heating *o*-bromo-benzoylbenzoic acid  $C_6H_4Br.CO.C_6H_4.CO_2H$  with  $H_2SO_4$  to 180°. On fusion with KOH it gives *erythro*-oxy-anthraquinone (Pechmann, *B.* 12, 2127).

(B. 2)-**Bromo-anthraquinone**  $C_{14}H_8BrO_2$ . [1877]. Formed by oxidation of tri-bromo-anthracene with  $CrO_3$  and HOAc (Graebe & Liebermann, *A. Suppl.* 7, 290). Yellow needles; may be sublimed; sl. sol. alcohol, m. sol. hot benzene. Converted by potash-fusion into alizarin.

**Di-bromo-anthraquinone**  $C_{14}H_6Br_2O_2$ . [2655].

**Formation.**—1. By brominating anthraquinone (Graebe & Liebermann, *A. Suppl.* 7, 289; Diehl, *B.* 11, 181).—2. By oxidation of tetra-bromo-anthracene or di-chloro-di-bromo-anthracene with  $CrO_3$  (G. & L.; Hammerschlag, *B.* 19, 1107).

**Properties.**—Boils with slight decomposition, sl. sol. boiling alcohol, m. sol. glacial HOAc. Potash-fusion at 250° gives alizarin. According to Perkin (*C. J.* 37, 554; *priv. com.*) the di-bromo-anthraquinone formed by the first method melts at 215° (or 250° cor.) and differs from that formed by the second method, which melts at 275° (or 281-5° cor.) by giving, on potash-fusion, not only alizarin but also flavopurpurin and anthrapurpurin (tri-oxy-anthraquinone).

**Tri-bromo-anthraquinone**  $C_{14}H_3Br_3O_2$ . [1867]. Prepared by the action of Br in presence of I upon anthraquinone or di-bromo-anthraquinone at 260° (Diehl, *B.* 11, 182). Yellow needles; insol. alcohol.

**Tri-bromo-anthraquinone**  $C_{14}H_3Br_3O_2$ . [3655]. From penta-bromo-anthracene,  $CrO_3$ , and HOAc (Hammerschlag, *B.* 10, 1213). Flat needles (by sublimation).

**Tetra-bromo-anthraquinone**  $C_{14}H_2Br_4O_2$ . [2955-3007]. Formed by oxidising hexa-bromo-anthracene [320] or by brominating tri-bromo-anthraquinone [1867] in presence of I (D.). Yellow needles.

**Tetra-bromo-anthraquinone**  $C_{14}H_2Br_4O_2$ . [above 370°]. Formed by oxidising hexa-bromo-anthracene [above 370°] (H.). Yellow needles.

**Penta-bromo-anthraquinone**  $C_{14}H_1Br_5O_2$ . Formed by oxidation of hepta-bromo-anthracene (D.). Sublimes with difficulty without melting; sl. sol. boiling toluene.

**DI-BROMO-DIANTHRYL**  $C_{18}H_8Br_2$ , [far above 300°]. Yellow prisms (from toluene). Formed by bromination of dianthryl dissolved in  $CS_2$  (Liebermann & Gimbel, *B.* 20, 1855).

**DI-BROMO-APOPHYLLIC ACID**  
 $C_8H_4Br_2NO_2$ , i.e.  $C_8H_4Br_2(CO_2H)(CO_2Me)$  or  $O_6NH_2MeBr(CO_2H) \begin{smallmatrix} CO \\ \diagup \diagdown \\ CBr \end{smallmatrix} CO$ . **Methyl-ether of bromo-pyridine dicarboxylic acid?** From bromo-tarconine (a derivative of narcotine) and Br (v. Gerichten, *A.* 210, 91). Hard prisms (con-

taining 2aq); sol. hot water. Its solutions give no pps. with salts of Pb, Ag, or Cu. Heated with conc. HCl it forms  $CO_2$ , MeCl, and a bromo-pyridine carboxylic acid (?) [1997].  
\* Salt.— $BaA_2$ , 3aq.

**DI-BROMO-APOPHYLLIN**  $C_{14}H_8Br_2N_2O_2$ . [2297]. From bromo-tarconine or bromo-apophyllenic acid and bromine-water (v. Gerichten, *A.* 210, 94). Six-sided tables (containing 4aq); sol. water, insol. ether. Alkalis form a deep-red solution. HCl at 150° gives  $CO_2$ , MeCl, di-bromo-pyridine, and di-bromo-pyridine methylochloride.

**Salts.**— $B^+HCl$ .— $B^{2+}HCl$ .— $Li^+H_2P_2Cl_4$ .— $B^+HBr$ .— $B^{2+}HBr$ .

**DI-BROMO-ATROLACTIC ACID** *v.*  $\beta$ -Di-bromo- $\alpha$ -oxy- $\beta$ -phenyl-propionic acid.

**BROMO-ATROPIC ACID**  $C_{11}H_9BrO_2$ , i.e. Ph.C<sub>6</sub>H<sub>4</sub>Br.CO<sub>2</sub>H. *Ezo-bromo- $\alpha$ -phenyl-acrylic acid*. [130]. From the compound of atropic acid (1 mol.) with HBr (2 mols.) by boiling with water (Fittig & Wurster, *A.* 195, 162). Slender needles (from water).

**TETRA-BROMO-AURIN**  $C_{14}H_6Br_4O_2$ . Formed by brominating aurin dissolved in HOAc (Dale & Schorlemmer, *C. J.* 35, 152; cf. Zulkowsky, *M.* 3, 465). Bronzed crystals. Alkalis form violet solutions.

**Salt.**— $A^+Ag_2$ ; dark violet insoluble pp.

**Ethyl ether  $A^+Et_2$** . [110°-115°]; microscopic reddish crystals; sol. alcohol, ether, and benzene (Ackermann, *B.* 17, 1626).

**BROMO-AZO BENZENE** *v.* pp. 374, 379.

**TETRA-BROMO-AZOPHENINE**  $C_{14}H_4Br_4N_2$ . [2437]. Formed by heating *p*-nitroso-di-phenylamine with *p*-bromo-aniline and *p*-bromo aniline hydrochloride at 100°. Greatly resembles azophenine (O. Fischer & Hepp, *B.* 20, 2181).

**BROMO-AZO-TOLUENE** *v.* p. 394.

**DI-BROMO-AZOXY-BENZENE** *v.* p. 427.

**BROMO-AZOXY-TOLUENE** *v.* p. 428.

**BROJO-BARBITURIC ACID**  $C_{14}H_8Br_2N_2O_2$ , i.e.  $CHBr \begin{smallmatrix} CO.NH \\ \diagup \diagdown \\ CO.NH \end{smallmatrix} CO$ . **Bromo-malonyl-urea.**

**Ureide of bromo malonic acid.** From di-bromo-barbituric acid by reduction with Na or Zn, or by evaporating with aqueous HCN (Bayer, *A.* 130, 184). Small needles; sl. sol. cold water.

**Salts.**— $NH_4A'$ .— $ZnA_2$ , 8aq. —  $ZnA_2$ , 6aq (Mulder, *B.* 12, 2309).

**Di-bromog-barbituric acid**  $C_4H_2Br_2N_2O_2$ . **Di-bromo-malonyl-urea.** Formed by the action of Br on barbituric, nitro-barbituric, nitroso-barbituric, and hydantonic acids (Bayer, *A.* 127, 199; 130, 130).

**Preparation.**—From di-bromo-oxy-methyl-uracil and fuming  $HNO_3$  (Behrend, *A.* 236, 62).

**Properties.**—Trimetric crystals. Sol. water, v. sol. hot alcohol and ether.

**Reactions.**—1. Boiling water forms alloxan and HBr.—2. HBr reduces it to hydantonic and barbituric acids.—3.  $H_2S$  forms dialuric acid.—4. Bromine water forms  $CO_2$  and tri-bromo-acetyl urea.—5. Alkalis form  $CO_2$ , tri-bromo-acetyl urea, and bromo-barbituric acid.—6. Thio-urea forms so-called thio-pseudo-uric acid  $C_4N_2H_2O_2S$  (Trzcinski, *B.* 16, 1057).—7. **Potassium sulphocyanide** forms sulphocyno-barbituric acid  $C_4N_4H_2SO_2$  (T.).

**Di-bromo-di-barbituric acid**  $C_4H_2Br_2N_4O_4$ , eq. Prisms (Bayer, A. 130, 145; cf. p. 440). —  $C_4H_2Br_2N_4O_4 \cdot HBr$ . Prisms, v. al. sol. water.

**DI-BROMO-BEHENIC ACID**  $C_{22}H_{34}Br_2O_2$ . [48°]. From erucic acid  $C_{22}H_{42}O_2$  and bromine (Hauksnecht, A. 143, 40; Otto, A. 135, 226). Nodules. Converted by alcoholic KOH to bromo-erucic acid,  $C_{22}H_{36}BrO_2$ , and behenic acid  $C_{22}H_{44}O_2$ . Moist  $Ag_2O$  forms oxy-erucic acid and di-oxy-behenic acid. Sodium amalgam forms erucic acid. Salts a.— $BaA^{+}$ ,  $PbA^{+}$ .

**Di-bromo-behenic acid**  $C_{22}H_{34}Br_2O_2$ . [54°]. From brassic acid and bromine (H.). Reduced by sodium-amalgam to brassic acid. Alcoholic KOH at 220° gives behenic acid.

**Tri-bromo-behenic acid**  $C_{22}H_{32}Br_3O_2$ . [32°]. From bromo-erucic acid and bromine (H.).

**Tetra-bromo-behenic acid**  $C_{22}H_{30}Br_4O_2$ . [78°]. From behenic acid and bromine (H.). Laminar (from alcohol).

**BROMO-BENZALDEHYDE** v. Bromo-benzoto ALDEHYDE.

**BROMO-BENZAMIDE** v. Amide of Bromo-benzoic acid.

**BROMO-BENZANILIDE** v. Anilide of Bromo-benzoic acid.

**BROMO-BENZENE**  $C_6H_5Br$ . Phenyl bromide. Mol. w. 157. [156°]. S.G.  $d_4^{20}$  1.4911.  $\mu_D$  1.5736. B. 55-81 (Brühl). S.V. 119-9 (Schiff, B. 19, 564). Vapour pressure: Ramsay & Young, C. J. 47, 616.

**Formation.**—1. From bromine and benzene, either boiling or in sunlight (Couper, A. Ch. [3] 52, 309; Schraun, B. 18, 606). The reaction is promoted by the presence of I (Ador & Rilliet, B. 8, 1287) or  $AlCl_3$  (Greene, C. R. 90, 40; Leroy, Bl. [2] 48, 210).—2. Formed by running a solution of  $NaNO_2$  into a hot solution of  $Cu_2Br_2$  and aniline in dilute  $H_2SO_4$  (Sandmeyer, B. 17, 2652).—3. By heating diazobenzene with a large excess of strong  $HBr$ ; the yield is 32 p.c. of the theoretical (Gassiorowski & Wajss, B. 18, 1938).—4. From phenol and bromide of phosphorus (Riche, A. 121, 357).

**Properties.**—Oil; not attacked by KOH, KCy, or  $AgOAc$ .

**Reactions.**—1. Boiling with  $AlCl_3$  produces benzene and di-bromo-benzenes (Dumreicher, B. 15, 1867).—2. Converted in the animal system into *p*-bromo-phenyl-mercapturic acid  $C_6H_4BrNSO_3$ , *p*-bromo-phenol, bromo-pyrocatechin, and bromo-hydroquinone (Mullmann & Preusse, H. 3, 156; Jaffé, B. 12, 1092).—3. Converted by conc.  $H_2SO_4$  into di-bromo-benzene sulphonic acid and bromo-benzene di-sulphonic acid (Herzig, M. 2, 192).—4.  $ClSO_3H$  forms  $C_6H_4Br(SO_3H)$  [14] and  $C_6H_3Br_2SO_3$   $C_6H_3Br_2$  (Beckurts & Otto, B. 11, 2061).—5. Heating with  $MeONa$  gives  $C_6H_4OMe$  and phenol (Blau, M. 7, 621). According to Mittica (B. 17, 2634) there is a second bromo-benzene [c. 62°].

***o*-Di-bromo-benzene**  $C_6H_4Br_2$ . [1:3]. [−1°]. [234°]. S.G.  $d_4^{20}$  2.003. Formed in small quantity in preparing *p*-di-bromo-benzene from benzene and Br (Riese, B. 2, 61; A. 164, 176). Formed also from *o*-nitroaniline *via* *o*-bromo-nitro-benzene (Körner, G. 4, 833).  $HNO_3$  forms chiefly di-bromo-nitro-benzene [58°].

***m*-Di-bromo-benzene**  $C_6H_4Br_2$ . [1:3]. (219°). S.G.  $d_4^{20}$  1.955.

**Formation.**—1. From (1,3,4)-di-bromo-aniline (Meyer & Stüber, A. 165, 169).—2. From *s*-di-bromo-aniline.—3. From *m*-di-nitro-benzene *via* *m*-nitro-aniline, *m*-bromo-nitro-benzene, and *m*-bromo-aniline (K.).—4. Together with the *p*-isomeride by the action of Br on benzene in presence of  $AlCl_3$  (Leroy, Bl. [2] 48, 211).

**Properties.**—Has not been solidified. Yields with  $HNO_3$  two nitro-derivatives [62°] and [83°]. Sodium acting on an ethereal solution forms diphenyl,  $C_{12}H_{10}Br_2$  [220°] and  $C_{18}H_{12}Br_2$  [250°] (Goldschmidt, M. 7, 45).

***p*-Di-bromo-benzene**  $C_6H_4Br_2$ . [1:1]. [80°]. (219°). S.V.S. 127-8 (Schiff).

**Formation.**—1. By bromination of benzene or bromo-benzene (Couper, A. Ch. [3] 52, 309; Riche & Bérard, A. 133, 51; Riese, A. 164, 162; Jannasch, B. 10, 1355).—2. From *p*-diazobromo-benzene perbromide by heating with alcohol (Griss, C. J. 20, 60).—3. From *p*-bromo-phenol and  $PBr_3$  (A. Mayer, A. 137, 219).—4. From benzene, Br, and  $FeCl_3$  (Scheufelen, A. 231, 188).

**Preparation.**—1. By treating benzene with Br and a little I.—2. Bromine (960 g.) is added slowly to benzene (240 g.) and  $AlCl_3$  (30 g.). On adding water in excess, the product deposited consists of crystals of the para-compound, with an oil, consisting chiefly of the meta-compound. This oil, however, contains some para-di-bromo-benzene in solution. To separate this, the oil is treated with fuming  $H_2SO_4$ . The meta-derivative is easily sulpho-nated in this way, but the para- is not affected. On adding a large excess of water, the solid  $C_6H_4Br_2$  (1:1) is pptd., and the clear solution of the meta-sulphonate distilled with steam gives  $C_6H_4Br_2$  [1:3] (Leroy, Bl. [2] 48, 211).

**Properties.**—Prisms or plates, isomorphous with *p*-di-chloro-benzene (Friedel, Bl. [2] 11, 38). Sublimable. Sl. sol. alcohol.

**Reactions.**—1. Heated for 30 minutes with  $AlCl_3$  (1 part) gives  $C_6H_3Br$ ,  $C_6H_4Br_2$  [1:3], and two tribromobenzenes,  $C_6H_3Br_2$  [1:2:4] and [1:3:5] (L.).—2.  $HNO_3$  forms a nitro-derivative [85°].—3. In ethereal solution sodium forms diphenyl, di-phenyl-benzene, and  $C_{12}H_{10}Br_2$  [265°] and  $C_{18}H_{12}Br_2$  [300°] (Riese, A. 164, 164; Goldschmidt, M. 7, 42).—4.  $MeI$  and Na form *p*-xylene.—5.  $NaOEt$  at 190° gives  $C_6H_4BrOEt$ , bromo-benzene, and benzene (Balbiano, G. 11, 401).—6.  $NaOMe$  forms  $C_6H_4BrOMe$ ,  $C_6H_3Br_2(OMe)_2$  and  $C_6H_3Br_2(OMe)(OH)$  (Blau, M. 7, 621).—7. Converted by conc.  $H_2SO_4$  into tetra- and hexa-bromo-benzene (Herzig, M. 2, 192).

***c*-Tri-bromo-benzene**  $C_6H_3Br_3$ . [1:2:3]. Mol. w. 315. [87°]. From (1,3,5,2)-di-bromo-nitro-aniline *via* tri-bromo-nitro-benzene, and tri-bromo-aniline (Körner, G. 4, 401). Tables (from alcohol); may be sublimed.

***s*-Tri-bromo-benzene**  $C_6H_3Br_3$ . [1:3:5]. [119°]. (278°). **Formation.**—1. From ordinary tri-bromo-aniline (Stüber, B. 4, 956; A. 165, 173; Reinke, A. 186, 271; Bässmann, A. 191, 206; Silberstein, J. pr. [2] 27, 104).—2. From (1,3,5)-di-bromo-aniline (K.).—3. In small quantity by the action of light on bromo-acetylene (Sabanejeff, J. R. 17, 176).

**Properties.**—Needles (from alcohol); sl. sol. alcohol. Boiling conc.  $H_2SO_4$  forms hexa-bromo-benzene (Herzig, M. 2, 197).  $NaOMe$

forms  $C_6H_4Br_2(OH)$  and  $C_6H_4Br_2OMe$  [77°] (Blau, *M.* 7, 621).

***o*-Tri-bromo-benzene**  $C_6H_3Br_3$  [1:2:4]. [44°]. (275°). *Formation*.—1. From hexa-bromo-benzene and alcoholic KOH (Mitscherlich, *P.* 35, 374; Lassaing, *Rev. Scient.* 5, 360).—2. From (1,3,4)-di-bromo-phenol and PBr<sub>3</sub> (Mayer, *A.* 137, 224).—3. From (1,3,4)-di-bromo-aniline (Griess, *Tr.* 154, 667).—4. From *o*-, *m*-, and *p*-di-bromo-benzene by nitration, reduction, and diazotisation (K.).—5. Got from each of the dibromobenzenes by heating with water and bromine at 250° (Wroblewsky, *A.* 192, 220).—6. From benzene, bromine, and FeCl<sub>3</sub> (Scheufelen, *A.* 231, 188).—7. As a by-product, in the preparation of  $C_6H_5Br$  by the action of Br upon  $C_6H_6$  in presence of AlCl<sub>3</sub> (Leroy, *Bl.* [2] 48, 213). *Properties*.—Needles; sl. sol. alcohol.

***s*-Tetra-bromo-benzene**  $C_6H_2Br_4$  [1:2:4:5]. Mol. w. 394. [175°]. *Formation*.—1. From *p*-di-bromo-benzene and Br at 150° (Riche a. Bérard, *A.* 133, 51).—2. From *o*-tri-bromo-benzene and Br. 3. From nitro-benzene and Br at 250° (Meyer, *B.* 15, 161).—4. From benzene (30 g.), FeCl<sub>3</sub> (5 g.), and bromine (210 g.); the mixture must be cooled (Scheufelen, *A.* 231, 187). *Properties*.—Long needles (from alcohol).

***u*-Tetra-bromo-benzene**  $C_6H_2Br_4$  [1:2:3:5]. [98.5°]. (329°). *Formation*.—1. From (1,3,5,2)-tri-bromo-phenol and PBr<sub>3</sub> (Körner, *A.* 137, 218; Mayer, *A.* 137, 227).—2. From (1,3,5,2)-tri-bromo-aniline (Würster a. Nölting, *B.* 7, 1561; V. v. Richter, *B.* 8, 1128; Silberstein, *J. pr.* [2] 27, 118).—3. From  $C_6H_4Br_2SO_2H$  by heating with HCl (Bäzmann, *A.* 191, 224).—4. One of the products obtained by heating tri-bromo-diazo-benzene nitrate with benzene (Silberstein, *J. pr.* [2] 27, 110). *Properties*.—Long needles, v. sl. sol. alcohol. HNO<sub>3</sub> (S.G. 1.50) gives a nitro-derivative [96°]; fuming HNO<sub>3</sub> (S.G. 1.51) gives a di-nitro-derivative [228°].

**Tetra-bromo-benzene**  $C_6H_2Br_4$ . [160°]. From *p*-nitro-benzoic acid and Br at 280° (Halberstadt, *B.* 14, 911). Needles (from alcohol).

**Tetra-bromo-benzene**  $C_6H_2Br_4$ . [138°]. From *p*-di-bromo-benzene and boiling conc. H<sub>2</sub>SO<sub>4</sub> (Herzig, *M.* 2, 195). One, if not both, of the two last-mentioned bodies is, doubtless, a mixture.

**Penta-bromo-benzene**  $C_6HBr_5$ . Mol. w. 473. [260°]. *Formation*.—1. From Br and nitro-benzene or di-nitro-benzene at 250° (Kekulé, *A.* 137, 172).—2. From *s*-tri-bromo-benzene and fuming H<sub>2</sub>SO<sub>4</sub> at 100° (Bäzmann, *A.* 191, 208).—3. From alizarin and BrI at 250° (Diehl, *B.* 11, 191). *Properties*.—Silky needles; v. sl. sol. alcohol, sol. benzene.

**Hexa-bromo-benzene**  $C_6Br_6$ . *Per-bromo-benzene*. [above 315°]. *Formation*.—1. By the action of Br containing I upon benzene, toluene, or benzene-azo-benzene at 250°–400° (Gessner, *B.* 9, 1505).—2. From tetra-bromo-quinone and PBr<sub>3</sub> at 280° (Raoult, *B.* 10, 403).—3. From *p*-di-bromo-benzene (or tri-bromo-benzene) and conc. H<sub>2</sub>SO<sub>4</sub> (Herzig, *M.* 2, 192).—4. By heating at 360° per-bromo-methane, per-bromo-ethane, per-bromo-butane, per-bromo-pentane, or per-bromohexane (Merz a. Weith, *B.* 11, 2235).—5. By heating benzene with bromine and Al<sub>2</sub>Br<sub>3</sub>.—6. By heating pentabromo-phenol with PBr<sub>3</sub> at 260° (Merz a. Weith, *B.* 16, 2890).—7. From bromine

(800 g.), FeCl<sub>3</sub>, and benzene (17 g.) in the cold. Good yield (110 g. instead of 119 g.) (Scheufelen, *A.* 231, 189). *Properties*.—Long needles (from toluene). V. sl. sol. alcohol and toluene.

#### \* BROMO-BENZENE *o*-SULPHONIC ACID

***o*-Bromo-benzene-*o*-sulphonic acid**  $C_6H_4BrSO_3H$  [1:2]. From *o*-amido-benzene sulphonic acid (Berndsen a. Limprieth, *A.* 177, 101; Bahlmann, *A.* 181, 203; 186, 315). Long deliquescent needles; v. e. sol. alcohol. — $KA'$  aq. — $BaA'$  aq. — $BaA'$  2aq. — $CaA'$  2aq. — $PbA'$  3aq. — $AgA'$ .

*Chloride*  $C_6H_4BrSO_3Cl$  [51°].

*Amide*  $C_6H_4BrSO_3NH_2$  [186°].

#### Bromo-benzene *m*-sulphonic acid

***m*-Bromo-benzene-*m*-sulphonic acid**  $C_6H_4BrSO_3H$  [1:3]. From amido-benzene *m*-sulphonic acid (Berndsen, *A.* 177, 92). Formed also by brominating benzene sulphonic acid or its silver salt (Ross Garriek, *Z.* [2] 5, 519; Genz, *B.* 2, 405; Nölting, *B.* 8, 819; Thomas, *A.* 186, 133). Very deliquescent. — $KA'$  aq. S. (of  $KA'$ ) 4.4 at 0°. — $PbA'$  2aq. — $PbA'$  3aq. —S. (of  $PbA'$ ) 5.78 at 7°. — $BaA'$  2aq. S. (of  $BaA'$ ) 3.5 at 14°.  $CaA'$ . — $AgA'$ .

*Chloride*  $C_6H_4BrSO_3Cl$ . Oil.

*Amide*  $C_6H_4BrSO_3NH_2$ . [154°].

#### Bromo-benzene *p*-sulphonic acid

***p*-Bromo-benzene-*p*-sulphonic acid**  $C_6H_4BrSO_3H$  [1:4] [88°]. Deliquescent needles. *Formation*.—1. By sulphonating bromo-benzene with H<sub>2</sub>SO<sub>4</sub>, ClSO<sub>3</sub>H, or SO<sub>3</sub> (Couper, *C. R.* 45, 230; Ross Garriek, *Z.* [2] 5, 549; Armstrong, *Z.* [2] 7, 321; Nölting, *B.* 8, 594).—2. From *p*-amido-benzene sulphonic acid (Meyer, *A.* 156, 291; Berndsen, *A.* 177, 92).

*Reactions*.—The K salt distilled with K<sub>2</sub>FeCy<sub>4</sub> gives terephthalonitrile.

*Salts*.—(Goslich, *B.* 8, 352; *A.* 180, 93). — $NH_4A'$ . — $KA'$ . — $CaA'$  2aq. — $BaA'$ . — $PbA'$  2aq. — $PbA'$ . — $ZnA'$  6aq. — $CuA'$  6aq. — $AgA'$ .

*Chloride*  $C_6H_4BrSO_3Cl$  [75°].

*Amide* [161°] (Bäzmann, *A.* 191, 217).

*Acetyl-amide*  $C_6H_4BrSO_3NHAc$  [199°].

*Amide*  $C_6H_4BrSO_3NHPh$  [119°].

#### Bromo-benzene *disulphonic acid*

***p*-Bromo-benzene-*p*-disulphonic acid**  $C_6H_3Br(SO_3H)_2$  [1:3:4?]. From the corresponding amido-benzene disulphonic acid (Zander, *A.* 198, 28). Deliquescent needles. — $BaA'$  3aq. — $PbA'$  aq.

*Chloride*  $C_6H_3Br(SO_3Cl)_2$  [101°].

*Amide*  $C_6H_3Br(SO_3NH_2)_2$  [210°].

#### Bromo-benzene *disulphonic acid*

***o*-Bromo-benzene-*o*-disulphonic acid**  $C_6H_3Br(SO_3H)_2$  [1:2:4].

*Formation*.—1. From the corresponding amido-benzene disulphonic acid (Zander, *A.* 198, 10).—2. From bromo-benzene *p*-sulphonic acid and SO<sub>3</sub> at 210° (Nölting, *B.* 7, 1311).

*Properties*.—Slender deliquescent needles.  $KA'$  aq. — $BaA'$  4aq. S. (of  $BaA'$ ) 6 at 22°. — $Ag_2A'$ .

*Chloride*  $C_6H_3Br(SO_3Cl)_2$  [103°].

*Amide*  $C_6H_3Br(SO_3NH_2)_2$  [239°].

#### Bromo-benzene *disulphonic acid*

***m*-Bromo-benzene-*m*-disulphonic acid**  $C_6H_3Br(SO_3H)_2$  [1 or 4:5:3]. From the corresponding amido-benzene disulphonic acid (Heinzelman, *A.* 188, 177). Deliquescent needles.

*Salts*.—( $NH_4$ ) $A'$ . — $BaA'$  2aq. — $PbA'$  2aq.

*Chloride*  $C_6H_3Br(SO_3Cl)_2$  [199°].

*Amide*  $C_6H_3Br(SO_3NH_2)_2$  [245°].

#### *o*-Di-bromo-benzene sulphonic acid

***o*-Di-bromo-benzene-*o*-sulphonic acid**  $C_6H_3Br_2SO_3H$  [1:2:3]. From the corresponding di-amido-benzene sulphonic acid (Sachse, *A.* 189, 153). Deliquescent prisms.

Salts.— $\text{KA}'$ .— $\text{BaA}'$ , 3aq. S. (of  $\text{BaA}'$ ) 143 at  $10^\circ$ .— $\text{CaA}'$ , 2aq.— $\text{PbA}'$ , 3aq.

Chloride  $\text{C}_6\text{H}_4\text{Br}_2\text{SO}_2\text{Cl}$  [127°].

Amide  $\text{C}_6\text{H}_4\text{Br}_2\text{SO}_2\text{NH}_2$  [215°].

*o*-Di-bromo-benzene sulphonic acid

$\text{C}_6\text{H}_3\text{Br}_2(\text{SO}_3\text{H})$  [1:2:4]. [67°]. From silver bromo-benzene *m*- or *p*-sulphonate and bromine (Limpricht a. Goslich, A. 186, 145). From  $\text{C}_6\text{H}_3\text{Br}(\text{NH})\text{SO}_3\text{H}$  by diazo-reaction (Langfurth, A. 191, 179; Spiegelberg, A. 197, 263). The free acid crystallises with 3aq. [68°].

Salts.— $\text{KA}'$ .— $\text{NH}_4\text{A}'$ .— $\text{BaA}'$ , 2aq.— $\text{BaA}'$ , 3aq. S. (of  $\text{BaA}'$ ) 3 at  $11^\circ$ .— $\text{CaA}'$ , 2aq.— $\text{PbA}'$ , 2aq. S. (of  $\text{PbA}'$ ) 26 at  $7^\circ$ .— $\text{AgA}'$ .

Chloride  $\text{C}_6\text{H}_3\text{Br}_2\text{SO}_2\text{Cl}$ . Oil.

Amide  $\text{C}_6\text{H}_3\text{Br}_2\text{SO}_2\text{NH}_2$  [175°].

*m*-Di-bromo-benzene sulphonic acid

$\text{C}_6\text{H}_3\text{Br}_2(\text{SO}_3\text{H})$  [1:3:5]. From dibrominated *o*- or *p*-amido-benzene sulphonic acid by the diazo-reaction (Limpricht, B. 8, 1066; A. 181, 201; Schmitt, A. 120, 154; Ienz, A. 181, 23). It is also a product of the action of conc.  $\text{H}_2\text{SO}_4$  on bromo-benzene (Herzig, M. 2, 192). Crystalline. Salts.— $\text{NH}_4\text{A}'$ .— $\text{KA}'$ .— $\text{BaA}'$ , 3½aq. S. (of  $\text{BaA}'$ ) 28 at  $18^\circ$ .— $\text{CaA}'$ , 3½aq.— $\text{PbA}'$ , 1½aq. S. (of  $\text{PbA}'$ ) 21 at  $18^\circ$ .

Chloride  $\text{C}_6\text{H}_3\text{Br}_2\text{SO}_2\text{Cl}$  [57-5°].

Amide  $\text{C}_6\text{H}_3\text{Br}_2\text{SO}_2\text{NH}_2$  [203°].

*m*-Di-bromo-benzene sulphonic acid

$\text{C}_6\text{H}_3\text{Br}_2\text{SO}_3\text{H}$  [1:3:4]. [80° when hydrated]; [110° anhydrous]. From  $\text{C}_6\text{H}_3\text{Br}_2(\text{NH})\text{SO}_3\text{H}$  [1:3:4:6] by diazo-reaction (Langfurth, A. 191, 184; Bässmann, A. 191, 232). Slender deliquescent needles (containing aq.). Sol. alcohol, insol. ether. With  $\text{HBr}$  at  $180^\circ$  gives  $\text{H}_2\text{SO}_4$  and *m*-di-bromo-benzene.

Salts.— $\text{NH}_4\text{A}'$ .— $\text{KA}'$ .— $\text{BaA}'$ , 2½aq. (L.).— $\text{BaA}'$ , 2aq. (B.). S. (anhydrous) 2 at  $10^\circ$  (L.); 1 at  $20^\circ$  (B.).— $\text{CaA}'$ , 3aq. S. (anhydrous) 8.34 at  $10^\circ$ .— $\text{PbA}'$ , 3aq. S. (anhydrous) 1.43 at  $8^\circ$ .— $\text{AgA}'$ .

Chloride  $\text{C}_6\text{H}_3\text{Br}_2\text{SO}_2\text{Cl}$  [79°].

Amide  $\text{C}_6\text{H}_3\text{Br}_2\text{SO}_2\text{NH}_2$  [190°] (anhydrous).

*p*-Di-bromo-benzene sulphonic acid

$\text{C}_6\text{H}_3\text{Br}_2(\text{SO}_3\text{H})$  [1:4:2]. [128°].  
Formation.—1. By bromination of silver *o*- or *m*-bromo-benzene sulphonate (Bahlmann, A. 181, 206; Limpricht, A. 186, 139).—2. By sulphonation of *p*-di-bromo-benzene (Douglas Williams, Z. [2] 7, 302; Hübner a. Williams, A. 167, 117; Wolz, A. 168, 81).—3. From nitrated bromo-benzene *o*- or *m*-sulphonic acid (Thomas, A. 186, 129; B.).—4. From brominated amido-benzene *o*-sulphonic acid (B.). Prisms (containing 3aq.) [98°]. Conc.  $\text{HBr}$  at  $250^\circ$  gives  $\text{H}_2\text{SO}_4$  and *p*-di-bromo-benzene.

Salts.—(cf. Borns, A. 187, 350).— $\text{NH}_4\text{A}'$ .— $\text{NaA}'$ , 1½aq.— $\text{KA}'$ , aq. S. (of  $\text{KA}'$ ) 5.79 at  $21^\circ$ .— $\text{AgA}'$ , 1½aq.— $\text{AgA}'$ , 3aq. S. (of  $\text{AgA}'$ ) 1.69 at  $10^\circ$ .— $\text{BaA}'$ , 1½aq. S. 1.01 at  $16^\circ$ .— $\text{BaA}'$ , aq.— $\text{BaA}'$ , 2aq.— $\text{BaA}'$ , 5aq.— $\text{CaA}'$ , 4aq. S. (of  $\text{CaA}'$ ) 6.90 at  $22^\circ$ .— $\text{CaA}'$ , 6aq.— $\text{CaA}'$ , 10aq.— $\text{PbA}'$ , 3aq. S. (of  $\text{PbA}'$ ) 2.56 at  $21^\circ$ .— $\text{PbA}'$ , 4aq.— $\text{CuA}'$ , 1½aq.

Chloride  $\text{C}_6\text{H}_3\text{Br}_2(\text{SO}_2\text{Cl})$  [72°].

Amide  $\text{C}_6\text{H}_3\text{Br}_2(\text{SO}_2\text{NH}_2)$  [193°].

Anhydride ( $\text{C}_6\text{H}_3\text{Br}_2\text{SO}_3$ ).O. Obtained by the action of fuming sulphuric acid upon *p*-di-bromo-benzene. Amorphous powder. Nearly insol. alcohol, ether, and benzene. By boiling alkalis it is converted into salts of the acid; very slowly attacked by boiling water.  $\text{PCl}_5$  con-

verts it into the chloride (Rosenberg, B. 19, 658).

*m*-Di-bromo-benzene di-sulphonic acid

$\text{C}_6\text{H}_2\text{Br}_2(\text{SO}_3\text{H})_2$ . From  $\text{C}_6\text{H}_2(\text{NO}_2)_2(\text{SO}_3\text{H})_2$  (Limpricht, B. 8, 290). Deliquescent.

*p*-Di-bromo-benzene disulphonic acid

$\text{C}_6\text{H}_2\text{Br}_2(\text{SO}_3\text{H})_2$ . Formed by sulphonating *p*-di-bromo-benzene (Borns, A. 187, 366). Small columns.— $\text{KA}'$ .— $\text{BaA}'$ , 4½aq.

Chloride  $\text{C}_6\text{H}_2\text{Br}_2(\text{SO}_2\text{Cl})_2$  [161°].

Amide  $\text{C}_6\text{H}_2\text{Br}_2(\text{SO}_2\text{NH}_2)_2$  [210°].

Tri-bromo-benzene sulphonic acid

$\text{C}_6\text{H}_2\text{Br}_3\text{SO}_3\text{H}$  [1:3:5:6]. [145°] (anhydrous). Formed by sulphonating *s*-tri-bromo-benzene (Reinke, A. 186, 271; Bässmann, A. 191, 206). Also from  $\text{C}_6\text{H}(\text{NH})\text{Br}_2\text{SO}_3\text{H}$  [1:2:4:6:3] by diazo-reaction (Langfurth, A. 191, 191). Six-sided tables (containing aq.) [95°]. Water at  $180^\circ$  forms  $\text{H}_2\text{SO}_4$  and *s*-tri-bromo-benzene.

Salts.— $\text{NH}_4\text{A}'$ , aq.— $\text{KA}'$ , 3aq.— $\text{KA}'$ , aq. S. (of  $\text{KA}'$ ) 81 at  $5.5^\circ$  (B.).— $\text{BaA}'$ , 9aq.— $\text{BaA}'$ , 6aq.— $\text{BaA}'$ , 2aq. S. (of  $\text{BaA}'$ ) 41 at  $5.5^\circ$  (L.); 22 at  $7.5^\circ$  (B.).— $\text{CaA}'$ , 8aq. S. (of  $\text{CaA}'$ ) 1.95 at  $7^\circ$  (L.); 3.5 at  $2.5^\circ$  (B.).— $\text{CaA}'$ , 4aq.— $\text{CaA}'$ , 7aq.— $\text{PbA}'$ , 2aq.— $\text{PbA}'$ , 9aq.— $\text{PbA}'$ , 2aq. S. (of  $\text{PbA}'$ ) 36 at  $7^\circ$  (B.).— $\text{AgA}'$ , aq.

Chloride  $\text{C}_6\text{H}_2\text{Br}_3\text{SO}_2\text{Cl}$  [65°].

Amide  $\text{C}_6\text{H}_2\text{Br}_3\text{SO}_2\text{NH}_2$ . Decomposes above  $220^\circ$ .

Tri-bromo-benzene sulphonic acid

$\text{C}_6\text{H}_2\text{Br}_3\text{SO}_3\text{H}$  [1:2:4:5]. [140° anhydrous]. From (1, 2, 4, 5)- or (2, 4, 1, 5)-di-bromo-amido-benzene sulphonic acid by diazo-reaction (Langfurth, A. 191, 188; Reinke, A. 186, 288; Knuth, A. 186, 303; Spiegelberg, A. 197, 282). Needles (containing 3aq.) [80°]. With  $\text{HBr}$  at  $200^\circ$  gives  $\text{H}_2\text{SO}_4$  and  $\text{C}_6\text{H}_2\text{Br}_3$  [1:2:4].

Salts.— $\text{NH}_4\text{A}'$ , aq.— $\text{KA}'$ , aq. S. (of  $\text{KA}'$ ) 1.03 at  $20^\circ$  (B.); 77 at  $22^\circ$  (S.).— $\text{BaA}'$ , 3aq. S. 1.22 at  $12^\circ$ .— $\text{BaA}'$ , 2aq.— $\text{BaA}'$ , 6aq.— $\text{CaA}'$ , 6aq.— $\text{PbA}'$ , 4aq.— $\text{AgA}'$ .

Chloride  $\text{C}_6\text{H}_2\text{Br}_3\text{SO}_2\text{Cl}$  [86-5°].

Amide  $\text{C}_6\text{H}_2\text{Br}_3\text{SO}_2\text{NH}_2$  [c. 225°].

Anhydride ( $\text{C}_6\text{H}_2\text{Br}_3\text{SO}_3$ ).O. Obtained by the action of fuming sulphuric acid upon tri-bromo-benzene (1:2:4). Amorphous powder. Almost insol. alcohol, ether, and benzene. By boiling aqueous alkalis it is converted into salts of the acid; only very slowly attacked by boiling water.  $\text{PCl}_5$  converts it into the chloride (cf. *supra*) (Rosenberg, B. 19, 651).

Tri-bromo-benzene sulphonic acid

$\text{C}_6\text{H}_2\text{Br}_3\text{SO}_3\text{H}$  [1:2:3:5]. From di-brominated amido-benzene *p*-sulphonic acid (Lenz, B. 8, 1067; A. 181, 29).— $\text{NH}_4\text{A}'$ .— $\text{KA}'$ .— $\text{CaA}'$ , 2½aq. S. 39 at  $20^\circ$ .— $\text{BaA}'$ , 3aq. S. (of  $\text{BaA}'$ ) 0.21 at  $18^\circ$ .— $\text{PbA}'$ , 3½aq. S. 0.56 at  $21^\circ$ .

Chloride  $\text{C}_6\text{H}_2\text{Br}_3\text{SO}_2\text{Cl}$  [127°].

Amide  $\text{C}_6\text{H}_2\text{Br}_3\text{SO}_2\text{NH}_2$  [210°].

Tri-bromo-benzene sulphonic acid

$\text{C}_6\text{H}_2\text{Br}_3\text{SO}_3\text{H}$  [1:2:3:5]. From silver (1, 2, 4)-di-bromo-benzene sulphonate and  $\text{Br}$  (Goslich, A. 186, 154). Is perhaps identical with the preceding.— $\text{BaA}'$ , 3½aq.

Chloride [121°]. Amide [152°].

Tri-bromo-benzene sulphonic acid

$\text{C}_6\text{H}_2\text{Br}_3\text{SO}_3\text{H}$  [1:3:4:5]. From nitrated (1, 3, 5)-di-bromo-benzene sulphonic acid (Lenz, A. 181, 39).— $\text{KA}'$ , aq.— $\text{BaA}'$ , aq.

Chloride  $\text{C}_6\text{H}_2\text{Br}_3\text{SO}_2\text{Cl}$  [86°].

Amide  $\text{C}_6\text{H}_2\text{Br}_3\text{SO}_2\text{NH}_2$ . Blackens at  $285^\circ$ .

**Tri-bromo-benzene-sulphonic acid**  
 $C_6H_3Br_3SO_3H$ . Possibly identical with the preceding. From nitrated (1, 4, 2)-di-bromo-benzene sulphonic acid (Borns, *A.* 187, 364).— $KA'$  3/4aq.— $BaA'$  2aq.

*Amide* [above 220°].

**Tri-bromo-benzene sulphonic acid**  
 $C_6H_3Br_3SO_3H$ . From silver bromo-benzene *o*-sulphonate and Br (Bahlmann, *A.* 181, 207).

*Chloride*  $C_6H_3Br_3SO_3Cl$ . [56°].

*Amide*  $C_6H_3Br_3SO_3NH_2$ . [202°].

**Tri-bromo-benzene sulphonic acid**  
 $C_6H_3Br_3SO_3H$ . Formed at the same time as the preceding (B.).

*Chloride*  $C_6H_3Br_3SO_3Cl$ . [72°].

*Amide*  $C_6H_3Br_3SO_3NH_2$ . [187°].

Nine tri-bromo-benzene sulphonic acids are here described, but only six are indicated by theory.

**Tri-bromo-benzene di-sulphonic acid**  
 $C_6H_2Br_3(SO_3H)_2$ . From benzene *m*-di-sulphonic acid by nitration, reduction, bromination to  $C_6H_2Br_3(NH_2)(SO_3H)_2$  and diazotisation (Heinzmann, *A.* 188, 183).—Salt:  $K_2A'$ .

**Tetra-bromo-benzene-sulphonic acid**

$C_6H_2Br_4SO_3H$  5aq [1:2:3:5:6].

*Formation*.—1. From  $C_6H_2Br_3(NH_2)SO_3H$  [1:3:5:4:6] by diazo-reaction (Bockurts, *A.* 181, 216; Langfurth, *A.* 191, 199; Knuth, *A.* 186, 229; Reinecke, *A.* 186, 282).—2. From  $C_6H_4Br_2$  and  $H_2SO_4$  (Bässmann, *A.* 191, 223). Needles. Not hygroscopic but v. sol. alcohol and water.

*Reaction*.—With conc.  $HBr$  at 150° gives  $H_2SO_4$  and (1,2,3,5)-tetra-bromo-benzene [98-5°].

*Salts*.— $KA'$ . S. 63 at 6°.— $BaA'$ . S. 37 at 12° (L.); 16 at 15° (Bä.).— $BaA'_2$  1/2aq.— $CaA'_2$  8aq. S. (of  $CaA'_2$ ) 54 at 3°; 66 at 19° (Bä.).— $NH_4A'$ .— $PbA'_2$  1/2aq. S. (of  $PbA'_2$ ) 89 at 11° (Bä.).— $PbA'_2$  4aq.

*Chloride*  $C_6H_2Br_4SO_3Cl$ . [96°].

*Amide*  $C_6H_2Br_4SO_3NH_2$ . Minute needles. Not melted at 300°.

**Tetra-bromo-benzene sulphonic acid**  
 $C_6H_2Br_4SO_3H$  [1:2:3:4:5]. [160°]. From (1,2,3,5)-tri-bromo-benzene sulphonic acid by nitration, reduction, and diazotisation (Lenz, *A.* 181, 23). Also in the same way from (1,2,4,5)-tri-bromo-benzene sulphonic acid (Spiegelberg, *A.* 197, 292). Laminæ (containing 2aq).

*Salts*.— $KA'$  aq. S. (of  $KA'$ ) 194 at 11°.— $NH_4A'$ . S. 95 at 11°.— $BaA'$  aq. S. (of  $BaA'$ ) 0204 at 10-5°.— $CaA'_2$  3aq. S. (of  $CaA'_2$ ) 159 at 11°.— $PbA'_2$  3aq. S. (of  $PbA'_2$ ) 0184 at 11°.— $AgA'_2$  aq. S. (of  $AgA'_2$ ) 146 at 11°.— $AgA'_2$  aq.

*Chloride*  $C_6H_2Br_4SO_3Cl$ . [120°].

*Amide*  $C_6H_2Br_4SO_3NH_2$ . Turns brown at 210°.

**Penta-bromo-benzene sulphonic acid**  
 $C_6HBr_5SO_3H$ . S. 518 at 10°. From either tetra-bromo-amido-benzene sulphonic acid by diazo-reaction (Bockurts, *A.* 181, 226; Heinzmann & Spiegelberg, *A.* 197, 306; Langfurth, *A.* 191, 205). Needles or plates (containing 2aq).

*Salts*.— $NH_4A'$ .— $KA'$  aq. S. (of  $KA'$ ) 116 at 10-5°.— $CaA'_2$  4aq. S. (of  $CaA'_2$ ) 78 at 14°.— $BaA'_2$  aq. S. (of  $BaA'_2$ ) 0088 at 13°.— $BaA'_2$  1/2aq.  $AgA'_2$  1/2aq.

*Chloride*  $C_6HBr_5SO_3Cl$ . [154°].

*Amide*  $C_6HBr_5SO_3NH_2$ . Decomposes at 250°.

**BROMO-BENZIDINE** v. BROMO-DI-AMINO-DIPHENYL.

***o*-BROMO-BENZOIC ACID**  $C_6H_4BrCO_2H$ , *o*.  
 $C_6H_4BrCO_2H$  [1:2]. Mol. w. 201. [148°].  
 (Z.; J. a. W.); [150°] (R.).

*Formation*.—1. From *o*-amido-benzoic acid (Richter, *B.* 4, 465).—2. By heating  $C_6H_4Br(NO_2)$  [1:3] with  $KCy$  at 180° (R.).—3. By oxidation of *o*-bromo-toluene (Zincke, *B.* 7, 1502; Rablis, *A.* 198, 99), *o*-bromo-diphenyl (Schultz, *A.* 207, 353), or *o*-bromo-benzyl alcohol (Jackson & White, *Am.* 2, 316).

*Properties*.—Long needles (from water); m. sol. water, v. sol. alcohol, and ether; slightly volatile with steam.

*Salts*.— $BaA'$ .— $BaA'_2$  2H<sub>2</sub>O. Et.— $CaA'_2$  3aq.— $KA'_2$  2aq.— $ZnA'_2$ .— $PbA'_2$ . HOEt.— $CuA'_2$  aq. [257°].— $HOCuA'$ .

*Methyl ether*  $MeA'$ . (247°).

*Ethyl ether*  $EtA'$ . (255°).

*Anilide*  $C_6H_4Br.CONHPh$ . [142°].

***m*-Bromo-benzoic acid**  $C_6H_4BrCO_2H$  [1:3]. [155°]. (280°).

*Formation*.—1. From  $AgOBz$  and Br (Peligot, *A.* 28, 246; Angerstein, *A.* 158, 2).—2. From benzoic acid and Br in the sunshin (Herzog, *N. Br. Arch.* 23, 16) or by heating them with water at 100° or 160° (Reinecke, *Z.* 1865, 116; 1869, 100; Hübner, *A.* 143, 233; 142, 131).—3. By heating benzamide with Br and water (Reinecke, *Z.* 1866, 367; Friedburg, *A.* 158, 26).—4. From *m*-amido-benzoic acid by diazo-reaction (Griess, *A.* 117, 25; Hübner, *A.* 222, 100).—5. From  $C_6H_4Br(NO_2)$  [1:4],  $KCy$ , and alcohol at 200° (Richter, *B.* 4, 464).—6. By oxidation of *m*-bromo-toluene (Wroblewsky, *Z.* [2] 5, 332; *A.* 168, 156) or *m*-bromobenzyl alcohol (Jackson, *Am.* 1, 93).—7. By the action of a hot solution of cuprous cyanide in potassium cyanide upon *m*-bromo-diazo-benzene-chloride (from *m*-bromaniline), and saponification of the crude nitrile (Sandmeyer, *B.* 18, 1496).—8. From *m*-di-bromo-benzene,  $ClCO_2Na$ , and  $Na$  (Wurster, *A.* 176, 149).

*Properties*.—Crystalline; very slightly volatile with steam; sl. sol. water, v. sol. alcohol.

*Reactions*.—1. *Polash-fusion* gives *m*- and a little *o*-oxy-benzoic acid (Richter, *Z.* 1869, 157; Barth, *A.* 159, 236).—2. The K salt fused with sodium formate gives isophthalic acid (V. Meyer & Ador, *A.* 159, 15).

*Salts*.— $CaA'_2$  3aq.— $BaA'_2$  4aq; needles.

*Methyl ether*  $MeA'$ . [32°].

*Ethyl ether*  $EtA'$ . (259°).

*Phenyl ether*  $PhA'$ . [65°].

*Chloride*  $C_6H_4Br.COCl$ . (239°).

*Amide*  $C_6H_4Br.CONH_2$ . [150°].

**Nitrile**  $C_6H_4BrCN$ . [38°]. (225°). From the amide (Engler, *B.* 1, 708). Formed also by the action of a hot solution of potassium cuprous cyanide upon *m*-bromo-diazo-benzene chloride (from *m*-bromaniline) (Sandmeyer, *B.* 18, 1496).

***p*-Bromo-benzoic acid**  $C_6H_4BrCO_2H$  [1:4]. [251°].

*Formation*.—1. By oxidation of *p*-bromo-toluene (Hübner, *A.* 143, 247; Jackson & Rolfe, *Am.* 9, 84), *p*-bromo-ethyl-benzene (Fittig & König, *A.* 144, 283), or *p*-bromo-benzyl bromide (Jackson, *Am.* 1, 93).—2. From *p*-bromaniline *via* *p*-bromo-thio-carbamide, the latter when heated with copper at 190° giving *p*-bromo-benzonitrile (Weith & Landolt, *B.* 8, 715).

*Properties*.—Small needles (from ether) or

plates (from water). V. sl. sol. water, v. sol. alcohol and ether.—AgA'.

*Ethyl ether* EtA' (236° uncor.) at 713 mm. Formed, together with *p*-bromo-benzyl-alcohol, by boiling *p*-bromo-benzyl bromide with alcoholic KOH (Ellis, J. pr. [2] 84, 341).

*Phenyl ether* PhA'. [117°]. Scales.

*Pyrogallyl ether* C<sub>6</sub>H<sub>3</sub>A'. [140°].

*Chloride*. [30°]. (246°). Needles.

*Amide* C<sub>6</sub>H<sub>4</sub>Br.CONH<sub>2</sub>. [186°].

*Anilide* C<sub>6</sub>H<sub>4</sub>Br.CONPhH. [197°]. Plates. On nitration it gives a dinitro-derivative. [214°]. (Raveill, A. 222, 178).

*Anhydride* (C<sub>6</sub>H<sub>4</sub>BrCO)<sub>2</sub>O. [213°]. From *p*-bromo-benzoyl chloride and sodium *p*-bromobenzoate (J. a. R.). Minute oblong rectangular plates (from CHCl<sub>3</sub>). Insol. water. Converted by hot H<sub>2</sub>OEt into the ethyl ether.

**Di-bromo-benzoic acid** C<sub>6</sub>H<sub>3</sub>Br<sub>2</sub>CO<sub>2</sub>H [1:2:3] [147°]. From (a)-bromo-amido-benzoic acid [1:2:3] by diazo-reaction (Hübner, A. 222, 105). From (1, 2, 3)-di-bromo-toluene (Neville a. Winther, B. 13, 965). Silky needles (from water). V. sol. hot water. Heated with H<sub>2</sub>SO<sub>4</sub> (3 vols.) and H<sub>2</sub>O (1 vol.) at 225° it gives *o*-di-bromobenzene [218.5°].

**Salts**.—BaA', 4¼aq. S. (of BaA') 4.44 at 16°. SrA', 4aq. —A'CuOH. —KA'raq.

This acid is perhaps identical with the di-bromo-benzoic acid [148°] prepared from *o*-nitrobenzoic acid, Br, and water at 200° (Claus a. Lade, B. 14, 1170).

**Di-bromo-benzoic acid** C<sub>6</sub>H<sub>3</sub>Br<sub>2</sub>CO<sub>2</sub>H [1:4:3] [153°]. From (β)-bromo-amido-benzoic acid [1:4:3] by passing nitrous acid gas into a mixture of the acid, HBr, glacial acetic acid and alcohol (Hübner, A. 222, 108). From nitro-*p*-di-bromo-benzene and alcoholic KCy (Richter, B. 7, 1146). From (1, 4, 3)-di-bromo-toluene by oxidation (Neville a. Winther, B. 13, 963). Long silky needles (from water). Volatile with steam. Heated with H<sub>2</sub>SO<sub>4</sub> (3 vols.) and water (1 vol.) at 225° gives *p*-di-bromo-benzene [89°].

**Salts**.—BaA', 1¼aq. —SrA', 4aq. —ZnA', —CaA', 3¼aq. —KA'aq.

This acid is probably identical with the di-bromo benzoic acid [153°] from *o*-nitro benzoic acid, Br, and water at 200° (Claus a. Lade, B. 14, 1170).

**Di-bromo-benzoic acid** C<sub>6</sub>H<sub>3</sub>Br<sub>2</sub>CO<sub>2</sub>H [1:3:2] [150°-167°]. By oxidising di-bromo-toluene from di-bromo-*m*-toluidine, [35°] (Neville a. Winther, G. J. 37, 441).

**Di-bromo-benzoic acid** C<sub>6</sub>H<sub>3</sub>Br<sub>2</sub>CO<sub>2</sub>H [1:3:4] [169°]. By oxidising di-bromo-toluene from di-bromo-*m*-toluidine [76°] (Neville a. Winther, C. J. 37, 441).

**Di-bromo-benzoic acid** C<sub>6</sub>H<sub>3</sub>Br<sub>2</sub>CO<sub>2</sub>H [1:3:5] [207°-210°] (N. a. W.); [209°] (R.); [214°] (H.).

**Formation**.—1. By oxidation of di-bromo-toluene [39°] from di-bromo-*p*-toluidine [73°] (Neville a. Winther, C. J. 37, 437).—2. From *m*-di-bromo-benzene by nitration and treatment with alcoholic KCy at 250° (V. v. Richter, B. 8, 1423).—3. From di-brominated *p*-amido-benzoic acid (Beilstein a. Geitner, A. 139, 4).—4. From C<sub>6</sub>H<sub>3</sub>Br(NH<sub>2</sub>)CO<sub>2</sub>H, aqueous HBr (S.G. 1.48), glacial acetic acid and N<sub>2</sub>O<sub>5</sub> at 15° (Hesemann a. Kohler, A. 222, 171).

**Properties**.—Plates (from alcohol) Needles (from other solvents).

**Salts**.—BaA', 4aq. —CaA', 5aq. —CdA', 4a —CaA', 6aq. —NaA' aq. —CdA', 4aq.

**Di-bromo-benzoic acid** C<sub>6</sub>H<sub>3</sub>Br<sub>2</sub>CO<sub>2</sub>H [1:8:2] [223°-227°]. Formed by heating benzoic acid with Br and water at 220° (Angerstein, A. 158, 10). Needles.—BaA', 2aq.

**Di-bromo-benzoic acid** C<sub>6</sub>H<sub>3</sub>Br<sub>2</sub>CO<sub>2</sub>H [1:2:4] [229°-230°] (B.); [233°] (N. a. W.).

**Formation**.—1. C<sub>6</sub>H<sub>3</sub>Br(NH<sub>2</sub>)CO<sub>2</sub>H [4:3:1] i treated with ether and N<sub>2</sub>O<sub>5</sub> and the diazo-derivative treated with HBr (Burghard a. Beutnagel, A. 222, 181).—2. By oxidising the corresponding di-bromo-toluene from brominated *p*-toluidine (Neville a. Winther, C. J. 37, 439).—3. A product of the action of Br on *p*-nitro-benzoic, or (1, 2, 4)-di-nitro-benzoic, acid (Halberstadt, B. 14, 908, 2215).

**Properties**.—Colourless needles (from water), tables (from alcohol).

**Salts**.—BaA', 4aq. —SrA', 4aq. —HOCuA'. —AgA'. —KA'raq.

*Ethyl ether* EtA'. [38°].

*Amide* C<sub>6</sub>H<sub>3</sub>Br<sub>2</sub>CONH<sub>2</sub>. [151°-152°].

**Tri-bromo-benzoic acid** C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>(CO<sub>2</sub>H). [235°]. From *m*-bromo-benzoic acid and Br (Reinecke, Z. [2] 5, 110). Tufts of slender silky needles; v. sl. sol. water. —NH<sub>4</sub>A'. —CaA', 5aq.

**Tri-bromo-benzoic acid** C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>CO<sub>2</sub>H. [1:3:5:6]. [187°]. From tri-brominated *m*-amido-benzoic acid (Vollbrecht, B. 10, 1708). Needles. —BaA', 5¼aq.

**Tri-bromo-benzoic acid** C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>CO<sub>2</sub>H. [195°]. From (1, 2, 4)-di-bromo-benzoic acid [229°] by nitration, reduction, and diazotisation (Smith, B. 10, 1706). Needles (from alcohol). —BaA', 5aq.

**Tri-bromo-benzoic acid** C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>CO<sub>2</sub>H. [178°]. From (1, 4, 5)-bromo-amido-benzoic acid (Lawrie, B. 10, 1705). Needles. —BaA', 3aq.

**Penta-bromo-benzoic acid** C<sub>6</sub>Br<sub>5</sub>CO<sub>2</sub>H. [235°]. From tri-bromo-benzoic acid and Br at 200° (Reinecke, Z. [2] 5, 110). Thin plates or flat needles (from alcohol); thick needles (from benzene); v. sl. sol. water. —NH<sub>4</sub>A'. —CaA', 6aq.

**Nitrile** C<sub>6</sub>Br<sub>3</sub>CN. [above 300°]. Obtained by brominating benzonitrile (Merz a. Weith, B. 16, 2892).

#### **o-BROMO-BENZOIC ALDEHYDE**

C<sub>6</sub>H<sub>3</sub>Br.CHO [1:2]. A heavy oil; formed by boiling *o*-bromo-benzyl bromide with aqueous lead nitrate (Jackson a. White, Am. S. 33; P. Am. A. 15, 269).

*o*-Bromo-benzoic aldehyde C<sub>6</sub>H<sub>3</sub>Br.CHO [1:3]. Oil (J. a. W.).

*p*-Bromo-benzoic aldehyde C<sub>6</sub>H<sub>4</sub>Br.CHO [1:4]. [57°] (Jackson a. White, B. 11, 57).

#### **BROMO-BENZOIC SULPHINIDE v. BROMO-SULPHO-BENZOIC ACID.**

**BROMO-BENZOPHENONE** C<sub>6</sub>H<sub>4</sub>BrO i.e. C<sub>6</sub>H<sub>4</sub>(CO.C<sub>6</sub>H<sub>4</sub>)Br. [81.5°]. From benzoic acid, bromo-benzene and P<sub>2</sub>O<sub>5</sub> at 190° (Kollarits a. Merz, B. 6, 547).

#### **BROMO-BENZOYL CHLORIDE v. Chloride of BROMO-BENZOIC ACID.**

#### **BROMO-DI-BENZYL v. BROMO-DI-PHENYLETHANE.**

**o-BROMO-BENZYL ALCOHOL** C<sub>6</sub>H<sub>3</sub>Br.OH i.e. C<sub>6</sub>H<sub>3</sub>Br.CH<sub>2</sub>.OH. [80°]. Prepared by digesting *o*-bromo-benzyl acetate with aqueous ammonia at 160°. Crystallises in white needles. Sol. hot water, ligroin, alcohol, ether, benzol, and CS<sub>2</sub>.

Volatile with steam (Jackson & White, *Am. J.* 2, 816; *B.* 13, 1218).

*m*-Bromo-benzyl alcohol  $C_6H_4Br.CH_2OH$ . From *m*-bromo-benzyl bromide and water at 130° (J. a. W.).

*p*-Bromo-benzyl alcohol  $C_6H_4Br.CH_2OH$ . [77°]. Prepared by boiling *p*-bromo-benzyl bromide with water for 3 days. Long elastic transparent needles. Sol. alcohol, ether, benzene, and  $CS_2$  (Jackson & Lowery, *Am. J.* 3, 246; *B.* 10, 1209).

*o*-BROMO-BENZYL-AMINE  $C_6H_4Br.CH_2NH_2$ . Prepared by acting on *o*-bromo-benzyl bromide with alcoholic ammonia at 100° for 2 hours (Jackson & White, *Am. J.* 2, 318). Colourless oil; sol. ether. Salts.— $BHCl$ : [208°]; needles.— $B_2H_4.PtCl_6$ .— $B_2H_4.CO_2$ : [95°].

*p*-Bromo-benzyl-amine  $C_6H_4Br.CH_2NH_2$ . From *p*-bromo-benzyl bromide and cold alcoholic  $NH_3$  (Jackson & Lowery, *Am. J.* 3, 251). Oil; volatile with steam.— $BHCl$ : [160°].— $B_2H_4.PtCl_6$ .— $B_2H_4.CO_2$ : [131°–133°]; small prisms.

Di-*o*-bromo-di-benzyl-amine  $(C_6H_4Br.CH_2)_2NH$ . [36°]. From *o*-bromo-benzyl bromide and alcoholic  $NH_3$  at 100°. Trimetric crystals; insol. water (Jackson & White, *Am. J.* 2, 318; *B.* 13, 1219).  $BHCl$ : [166°].— $B_2H_4.PtCl_6$ .

Di-*p*-bromo-di-benzyl-amine  $(C_6H_4Br.CH_2)_2NH$ . [50°].— $BHCl$ : [183°].— $B_2H_4.PtCl_6$  (J. a. W.).

Tri-*o*-bromo-tri-benzyl-amine  $(C_6H_4Br.CH_2)_3N$ . [122°]. From *o*-bromo-benzyl bromide and alcoholic  $NH_3$  at 100° (J. a. W.). Small prisms.— $B_2H_4.PtCl_6$ .

Tri-*p*-bromo-tri-benzyl-amine  $(C_6H_4Br.CH_2)_3N$ . Crystals (from ligroin) [92°]; (from ether) [78°]. Slender needles; the hydrochloride could not be obtained.— $BHBr$ : [270°]; insol. water.— $B_2H_4.PtCl_6$  (Jackson & Lowery, *Am. J.* 3, 252).

*o*-BROMO-BENZYL BROMIDE  $C_6H_4Br.CH_2Br$  [1:2]. [30°]. (250°–260°). Di-bromo-toluene. Prepared by brominating *o*-bromo-toluene (Jackson, *Am. J.* 1, 93; 2, 315; *B.* 13, 1218). Very pungent; volatile with steam. Converted in ethereal solution by Na into anthracene, phenanthrene, *s*-di-phenyl-ethane, and other products.

*m*-Bromo-benzyl bromide  $C_6H_4Br.CH_2Br$  [1:3]. [41°]. From *m*-bromo-toluene and Br (Jackson, *Am. J.* 1, 93; *B.* 9, 932). Pungent plates; slightly volatile with steam; very volatile with ether-vapour.

*p*-Bromo-benzyl bromide  $C_6H_4Br.CH_2Br$  [1:4]. [62°]. Formed by brominating *p*-bromo-toluene or benzyl bromide (Jackson, *Am. J.* 1, 93; Schramm, *B.* 17, 2922; 18, 350). Needles (from alcohol); volatile with steam; very pungent. Alcoholic KOH forms *p*-bromo-benzyl alcohol and *p*-bromo-benzoic ether (Elbs, *J. pr.* [2] 31, 340).

BROMO-BENZYL CYANIDE *v.* Nitrile of Bromo-phenyl-acetic acid.

BROMO-BENZYLIDENE-PHTHALIMIDINE  $C_{12}H_9ONBr$ . Phthalimidy-bromo-benzyl. [210°]. Glistening needles. Formed by the action of bromine upon decybenzoic-carboxylamide  $C_{10}H_7(CO.NH_2).CO.CH_2.C_6H_5$  dissolved in chloroform (Gabriel, *B.* 18, 2435).

TETRA-BROMO-BENZYLIDENE-DI-TOLYL-DIAMINE  $(PhCH_2)_2N(C_6H_4Br)_2$ . [160°–165°]. From benzylidene-di-*p*-tolyl-diamine and Br (Massara, *G.* 10, 370).

# *p*-BROMO-BENZYL MERCAPTAN

$C_6H_4Br.CH_2SH$ . [25°]. From *p*-bromo-benzyl bromide and alcoholic KHS (Jackson & Hartshorn, *Am. J.* 5, 268). Crystalline mass; insol. water and glacial HOAc; sol. alcohol, ether, and benzene.— $Hg(SC_2H_5)_2$ : sol. hot alcohol.

DI-BROMO-BENZYL-PHENOL  $C_6H_3Br_2.OH$ . [175°]. From benzyl-phenol in  $CS_2$  and Br (Paterno & Fietti, *G.* 3, 251). Amorphous.

BROMO-*o*-BENZYL-PHENOL SULPHONIC ACID  $C_6H_3Br(OH)BrSO_3H$ . Salt. KA'. From Br and  $C_6H_3Br_2(OH)SO_3K$  (Rennie, *C. J.* 49, 409).

Bromo-*p*-benzyl-phenol sulphonic acid  $C_6H_3Br(OH)BrSO_3H$  [1:4x:2].

Salt.—KA' (Rennie, *C. J.* 41, 35).

*p*-BROMO-BENZYL SULPHIDE  $(C_6H_4Br.CH_2)_2S$ . [59°]. Prepared by boiling *p*-bromo-benzyl bromide with alcoholic Na<sub>2</sub>S. Large thin plates. Aromatic odour. Insol. water. Sol. ether, benzene, and  $CS_2$  (Jackson & Hartshorn, *Am. J.* 5, 267).

*p*-Bromo-benzyl disulphide  $(C_6H_4Br.CH_2)_2S_2$ . [88°]. Prepared by exposing the mercaptan to air, and also by acting on *p*-bromo-benzyl bromide with alcoholic Na<sub>2</sub>S. Needles. Insol. water; sol. ether, benzene, and  $CS_2$  (Jackson & Hartshorn, *Am. J.* 5, 269).

*p*-BROMO-BENZYL SULPHOCYANIDE  $C_6H_4Br.SCN$ . [25°]. From *p*-bromo-benzyl bromide and potassium sulphocyanide. The *o*-isomeride is an oil (Jackson & Lowery, *B.* 10, 1209; *Am. J.* 3, 250).

DI-*p*-BROMO-DI-BENZYL SULPHONE  $(C_6H_4Br.CH_2)_2SO_2$ . [180°]. From the sulphide and  $ClO_2$  in HOAc. Needles (Jackson & Hartshorn, *Am. J.* 5, 269).

BROMO-BENZYL SULPHONIC ACID *v.* Bromo-toluene sulphonic acid.

DI-BROMO-BETORCIN  $C_{12}Br_2Me_2(OH)_2$ . [155°]. From tetra-bromo-betorein and  $H_2O$ . Also by boiling a mixture of betorein (3 pts.), bromine (8 pts.) and  $Cl_2$  (100 vols.). The product is recrystallised from light petroleum (Stenhouse & Groves, *C. J.* 37, 341). Long needles.

Tetra-bromo-betorein  $C_{12}Br_4Me_4(OH)_4$ . [101°]. From bromine (5 pts.), water (100 vols.) and betorein (1 pt.). Dissolved in water (50 pts.). Crystallised from light petroleum (S. a. G.).

Large colourless prisms. V. sol. ether, benzene and  $CS_2$ , less so in petroleum.

BROMO-BRASILIN  $C_{12}H_{13}BrO_2$ . Obtained by brominating acetyl-brasilin and saponifying the product. Glistening red plates. V. sol. water. Dissolves in KOH with a red colour.

Tetra-acetyl derivative  $C_{12}H_9Br(OAc)_4O$ . [201°] (Bachka & Erck, *B.* 17, 685; 18, 1140).

Tri-bromo-brasilin  $C_{12}H_{11}Br_3O_2$ .

Tetra-acetyl derivative  $C_{12}H_9Br(OAc)_4O$ . [147°]. Small white needles; very oxidisable (B. a. E.).

Tetra-bromo-brasilin  $C_{12}H_{11}Br_4O_2$ . Slender red needles. Dissolves in alkalis with a violet colour. Obtained by bromination of brasilin.

Tetra-acetyl derivative  $C_{12}H_9Br(OAc)_4O$ . [222°] (B. a. E.).

BROMO-BUTANE *v.* Butyl bromide.

*n*-Di-bromo-butane  $C_4H_8Br_2$ , *i.e.*  $CH_3Br.CHBr.CH_2CH_3$ , Butylenebromide. (166°). S.G. 1.820. Formed by the action of Br on *n*-butylene or *n*-butyl bromide (Wurtz, *A.* 162, 38).

- Lienemann, *A.* 161, 199; Grabowsky a. Saytzeff, *A.* 179, 882). Na forms  $\text{CH}_3\text{CHBrCH}_2\text{CH}_3$ .  
*as*-Di-bromo-butane  $\text{CH}_3\text{CHBrCHBrCH}_3$ . (188°). S.G. 2.182. From  $\text{CH}_3\text{CHBrCH}_2\text{CH}_3$  and Br. Converted by  $\text{PhO}$  and excess of water at 150° into methyl ethyl ketone (Wurtz, *A.* 144, 236; Etteckoff, *J. R.* 10, 219).  
 Di-bromo-isobutane  $(\text{CH}_3)_2\text{CBrCH}_2\text{Br}$ . *Isobutylene bromide*. (149°). S.G. 1.18; 1.7434; 2.17308. M. M. 11-890 at 14.75° (Perkin). From isobutylene and Br (Lienemann, *A.* 162, 36). By heating with excess of water at 150° it is converted into isobutyric aldehyde; if  $\gamma\text{-bO}$  is also present some di-oxy-butanone is also formed (Etteckoff, *J. R.* 10, 214).  
 Di-bromo-butane  $\text{C}_4\text{H}_8\text{Br}_2$ . (153°-162°). Formed by brominating butane (Carius, *A.* 126, 215).  
 Tri-bromo-isobutane  $\text{C}_4\text{H}_7\text{Br}_3$ . *i.e.*  $(\text{CH}_3)_2\text{CBrCH}_2\text{Br}$ . (173°-183°) at 235 mm. S.G. 2.15. From isobutylene and Br (Norton a. Williams, *Am.* 9, 88).  
 Tri-bromo-isobutane  $\text{C}_4\text{H}_7\text{Br}_3$ . *i.e.*  $(\text{CH}_3)_2\text{CBrCH}_2\text{Br}$ . (155°-161°) at 235 mm. From  $(\text{CH}_3)_2\text{CCHBr}$  and Br (N. a. W.).  
 Tri-bromo-butane  $\text{C}_4\text{H}_7\text{Br}_3$ . (208°-215°). From bromo-butylene (82°-92°) (Caventou, *A.* 127, 93).  
 Tetra-bromo-butane  $\text{C}_4\text{H}_6\text{Br}_4$ . *i.e.*  $\text{CH}_2\text{BrCHBrCHBrCH}_2\text{Br}$ . *Butinene- or pyrrolylene-tetra-bromide*. (119°). Formed by combination of bromine with the butinene from di-methyl-pyrrolidine or from erythrite. From erythrite, vinyl-ethylene, or gas oils (Caventou, *A.* 127, 95; B. 6, 70; Henninger, *B.* 6, 70; Grimaux a. Cloez, *C. R.* 104, 1446; *Bl.* 2, 48, 31). From the gas obtained by passing acetylene mixed with ethylene through a red-hot tube (Fruhier, *Bl.* 2, 20, 72). On distillation it is partially converted into the following body. Colourless needles (from alcohol). Insol. cold petroleum-ether (Ciamician a. Magnaghi, *B.* 19, 566).  
 Tetra-bromo-butane  $\text{CH}_2\text{CBr}_2\text{CBr}_2\text{CH}_2$  (?) (40°). *Erythrene isobromide*. *Erythrite tetra-bromhydrin*. Formed, together with the isomeride (119°), by combining butinene from erythrite with bromine. Large colourless tri-metric prisms or tables,  $\text{ac} = 9776:1:1682$  (Ciamician a. Magnaghi, *B.* 19, 569). V. sol. ether, alcohol, and petroleum-ether. Alcoholic KOH converts both this and the preceding into the same di-bromo-butinene  $\text{C}_4\text{H}_6\text{Br}_2$ , which rapidly polymerises. The latter absorbs Br, forming  $\text{C}_4\text{H}_5\text{Br}_3$  [67°] and  $\text{C}_4\text{H}_4\text{Br}_4$  [170°].  
 Tetra-bromo-butane  $\text{C}_4\text{H}_6\text{Br}_4$ . From Br and di-bromo-butylene (140°-150°) from fusel oil *and* butylene (Caventou, *A.* 127, 93). Crystalline; decomposes at 200°.  
 Tetra-bromo-butane  $\text{CH}_3\text{CH}_2\text{CBr}_2\text{CHBr}_2$ . From butinene prepared from methyl ethyl ketone by successive treatment with  $\text{PCl}_5$  and alcoholic KOH. Sublimes at 105° (Bruylants, *B.* 8, 410).  
 Tetra-bromo-isobutane  $\text{C}_4\text{H}_8\text{Br}_4$ . [205°]. From di-bromo-isobutylene (155°) (Norton a. Williams, *Am.* 9, 87).  
 Hexa-bromo-butane  $\text{C}_4\text{H}_4\text{Br}_6$ . [109°]. Obtained by brominating isobutyl bromide at 170°. The yield is 90 p.c. of the theoretical (Merz a. Weith, *B.* 11, 2245).  
 Hexa-bromo-butane  $\text{C}_4\text{H}_4\text{Br}_6$ . *i.e.*  $\text{Br}_2\text{CHBrCHBrCHBrCH}_2\text{Br}$ . S.G. 1.29. Forms together with the following, by heating erythritetabromhydrin with Br at 180° (Colson, *Z.* [2] 48, 62). Liquid; v. sol. ether, sl. sol. alcohol. Dilute KOH at 130° converts it into potassium erythrate.  
 Hexa-bromo-butane  $\text{C}_4\text{H}_4\text{Br}_6$ . [170°]. S.C. 3-4. Formed in small quantity as above (C. Pearly scales, sl. sol. ether and alcohol. Fumin  $\text{HNO}_3$  forms an oil  $\text{C}_4\text{H}_2(\text{NO}_2)_6$  (S.G. 1.81).  
 DI-BROMO-BUTYL ALCOHOL  $\text{C}_4\text{H}_9\text{Br}_2\text{O}_2$ . *i.e.*  $\text{CH}_3\text{CHBrCHBrCH}_2\text{OH}$ . Oil. From butenyl alcohol  $\text{CH}_3\text{CHCH}_2\text{CH}_2\text{OH}$  and Br (Lieben a. Zeisel, *M.* 1, 828). Boiling water forms tri-oxybutane.  
*as*-DI-BROMO-*n*-BUTYL-BENZENE  $\text{C}_{10}\text{H}_{12}\text{Br}_2$ . *i.e.*  $\text{C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{CHBrCH}_2\text{Br}$ . From phenyl-butylene and Br (Aronheim, *A.* 171, 229). Oil. *Reactions*.—1. Red-hot soda-lime forms naphthalene.—2.  $\text{HNO}_3$  forms a little bromophenyl-propionic acid.  
*By*-Di-bromo-*n*-butyl-benzene  $\text{C}_{10}\text{H}_{12}\text{Br}_2$ .  $\text{CH}_3\text{CH}_2\text{CHBrCH}_2\text{Br}$ . [67°]. From butenyl-benzene and Br (Perkin, *C. J.* 32, 668).  
*By*-Di-bromo-*n*-butyl-benzene  $\text{C}_{10}\text{H}_{12}\text{Br}_2$ .  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{Br}_2$  (?). From butyl-benzene and Br in sunlight. Unstable oil (Schramm, *B.* 18, 1276).  
 Di-bromo-*n*-butyl-benzene  $\text{C}_{10}\text{H}_{12}\text{Br}_2$ . [70°]. From *n*-butyl-benzene and Br first in sunlight, then heated in the dark (Radziszewski, *B.* 9, 261).  
*as*-Di-bromo-isobutyl-benzene  $\text{C}_{10}\text{H}_{12}\text{Br}_2$ .  $\text{C}_6\text{H}_5\text{CHBrCHBrMe}$ . From phenyl-isobutylene and Br (Perkin, *C. J.* 35, 138).  
 Tri-bromo-isobutyl benzene  $\text{C}_{10}\text{H}_{11}\text{Br}_3$ . [64°]. From the preceding by successive treatment with alcoholic KOH and Br (P.).  
 BROMO-BUTYLENE  $\text{C}_4\text{H}_6\text{Br}$ . *i.e.*  $(\text{CH}_3)_2\text{CCHBr}$ . (91°). *Isocrotyl bromide*. From isobutylene bromide and alcoholic KOH (Butlerow, *Z.* 1870, 521). Alcoholic KOH at 170° forms  $(\text{CH}_3)_2\text{CCHBr}$ . Moist  $\text{Ag}_2\text{O}$  at 100° gives isobutyric acid.  $\text{NH}_3$  has no action.  
 Bromo-butylene  $\text{C}_4\text{H}_6\text{Br}$ . (82°-92°). From fusel oil butylene by successive treatment with Br and alcoholic KOH (Caventou, *A.* 127, 93).  
 Bromo-butylene  $\text{C}_4\text{H}_6\text{Br}$ . (87° i.v.). From di-bromo-methyl-ethyl-acetic acid and aqueous  $\text{Na}_2\text{CO}_3$  (Jaffé, *A.* 135, 300; Pagenstecher, *A.* 125, 126).  
 Bromo-butylene  $\text{C}_4\text{H}_6\text{Br}$ . (97°). Formed by boiling the di-bromide of angelic acid with water (Jaffé, *A.* 135, 300).  
 Di-bromo-iso-butylene  $\text{C}_4\text{H}_6\text{Br}_2$ . (155°). From tri-bromo-iso-butane (155°-161°) at 235 mm. (Norton a. Williams, *Am.* 9, 87).  
 Di-bromo-butylene  $\text{C}_4\text{H}_6\text{Br}_2$ . (140°-150°). From tri-bromo-butane (208°-215°). Forms a crystalline di-bromide  $\text{C}_4\text{H}_4\text{Br}_4$ , which decomposes without melting at 200° (Caventou, *A.* 127, 93).  
 Di-bromo-butylene  $\text{C}_4\text{H}_6\text{Br}_2$ . (148°-168°). From crotonylene and Br (Caventou, *A.* 127, 349).  
 Di-bromo-butylene  $\text{C}_4\text{H}_6\text{Br}_2$ . From tetra-bromo-butane [119°] (from erythrite) and alcoholic KOH. Rapidly polymerises. Combines readily with bromine (Grimaux a. Cloez, *Bl.* [2] 48, 31).  
 Di-bromo-butylene  $\text{C}_4\text{H}_6\text{Br}_2$ . *i.e.*  $\text{CH}_3\text{CHCHBrCH}_2\text{Br}$ . (190°-200°). From the

oils deposited by compressed gas, by adding less than the calculated quantity of Br and fractionally distilling. Combines readily with Br, forming  $C_4H_5Br$  [119°] (G. a. C.).

Hexabromobutylene  $C_4Br_6H_2$ . [53°]. Prepared by further bromination of hexabromoisobutane (Merz a. Weith, B. 11, 2240).

**$\alpha$ -BROMO- $n$ -BUTYRIC ACID**  $C_4H_7BrO_2$ , i.e.  $CH_3CH_2CHBrCO_2H$ . (214°-217°). (110°) at 8 mm. S.G.  $\frac{4}{4}$  1.51. S. 7.

**Formation.**—1. By heating butyric acid with Br at 140°; or by the action of Br on silver butyrate (Friedel a. Machuca, A. 120, 279; Suppl. 2, 70; Gorup-Besanez a. Klinksieck, A. 118, 248; Naumann, A. 119, 115; Ley, J. R. 9, 129; Urech, A. 165, 93; Tupoleff, A. 171, 249). — 2. From crotonic acid and HBr. — 3. From the bromide and water (Kaschirski, C. C. 1881, 278).

**Properties.**—Oil; mixes with alcohol and ether. NEt., whether dry or in aqueous solution, forms  $\alpha$ -oxy-butyric acid (Duvillier, Bl. [2] 48, 3). NaOHAg acts similarly.

**Salts.**— $PbA_2$ .— $PbA_2 \cdot 2H_2O$ .— $AgA$ .  
**Methyl ether** MeA'. (165°-172°).

**Ethyl ether** EtA'. (178°) (Löwen, J. pr. [2] 33, 102). S.G.  $\frac{4}{4}$  1.345. Dry NaOEt forms an ether  $C_4H_9O_2(OR)_2$ . (252°) (Krestownikoff, A. 208, 348).

**Bromide**  $C_4H_6Br_2O_2$ . (173°). From butyryl bromide and Br.

**$\beta$ -Bromo-butyric acid**  $CH_3CHBrCH_2CO_2H$ . Formed in small quantity in the preparation of the  $\alpha$ -acid from crotonic acid and HBr (Hemilian, A. 174, 325).

**$\gamma$ -Bromo-butyric acid**  $CH_3BrCH_2CH_2CO_2H$ . [33°]. From butyrolactone and HBr (Henry, C. R. 102, 368). Tables or plates; sl. sol. water, v. sol. ether.

**Methyl ether** MeA'. (187°). S.G.  $\frac{4}{4}$  1.15.  
**Ethyl ether** EtA'. (197°). S.G.  $\frac{4}{4}$  1.36.

**$\alpha$ -Bromo-isobutyric acid**  $(CH_3)_2CBrCO_2H$ . [48°]. (199°). S.G.  $\frac{4}{4}$  1.52. From isobutyric acid and Br (Markownikoff, A. 153, 229; Hell a. Waldauer, B. 10, 448). Tables. Boiling water converts it into  $\alpha$ -oxy-isobutyric acid, KHS acts similarly (Löwen, J. pr. [2] 33, 105); boiling baryta-water forms also  $CH_3CMeCO_2H$  (Engelhorn, A. 200, 68).

**Ethyl ether** EtA'. (164° cor.). S.G.  $\frac{4}{4}$  1.13. Oil; smelling of raspberries and peppermint (Markownikoff, A. 182, 336; Hell a. Wittekind, B. 7, 320; Löwen, J. pr. [2] 33, 106).

**Bromide**  $(CH_3)_2CBrCO_2Br$ . (163°).

**$\beta$ -Bromo-isobutyric acid**  $CH_3BrCHMeCO_2H$ . [22°]. From  $\alpha$ -methyl-acrylic acid and cold conc. HBr. Crystals (from CS.). Boiling alkalis convert it into  $\alpha$ -methyl-acrylic acid and a little propylene (Fittig a. Engelhorn, A. 200, 65).

**$\alpha$ , $\beta$ -Di-bromo-butyric acid**  $CH_3CH_2CBr_2CO_2H$ . (140°) at 3 mm. S. 3. S.G. 1.96. From bromo-butyric acid and bromine (Schneider, J. 1861, 458; Michael a. Norton, Am. 2, 15; Otto a. Fromme, A. 233, 375). Thick oil. Water or baryta-water at 120° forms  $\alpha$ -bromo-crotonic acid (Erl-nmeyer a. Müller, B. 15, 49). Converted by reduced silver into di-ethyl-maleic or xeronic acid  $CO_2H.CEt:C.Et.CO_2H$ , butyric acid being formed.

**$\alpha$ , $\beta$ -Di-bromo-butyric acid**

$CH_3CHBrCHBrCO_2H$ . [87°].

**Preparation.**—From Br and crotonic or isocrotonic acid dissolved in CS. (Körner, A. 187, 234; Michael a. Norton, Am. 2, 12; B. 14, 1209; C. Kolbe, J. pr. 133, 386).

**Properties.**—Large transparent prisms (from CS.); sol. alcohol, ether, and hot water.

**Reactions.**—1. Boiled with water or NaCO<sub>3</sub>, it gives  $\beta$ -bromo-propylene, bromo-oxy-butyric acid, di-oxy-butyric acid, and bromo-crotonic acid. Water gives chiefly bromo-oxy-butyric acid; NaCO<sub>3</sub> gives more bromo-propylene, but no propionic aldehyde. — 2. Warmed with a solution of NaOH it gives bromo-crotonic acid.

**Di-bromo-iso-butyric acid**

$CH_3Br.CBrMe.CO_2H$ . [48°].

**Preparation.**—By adding Br to methacrylic acid dissolved in CS. (C. Kolbe, J. pr. [2] 25, 373). Long prisms (from CS.). Boiling with water or NaCO<sub>3</sub> produces CO<sub>2</sub>, acetone, some propionic aldehyde, a very little bromo-methacrylic acid, 63°, and bromo-oxy-iso-butyric acid (q. v.). Warmed with solution of NaOH it gives bromo-methacrylic acid and HBr.

**Tri-bromo-butyric acid**  $C_4H_3Br_3O_2$ , i.e.

$CH_3CBr_2CHBrCO_2H$ ? [114°]. From  $\beta$ -bromo-crotonic acid in CS. and Br (Michael a. Norton, Am. 2, 14). Rhombic plates; sol. alcohol and hot water; sublimes readily.

**Tri-bromo-butyric acid**  $C_4H_3Br_3O_2$ , i.e.

$CH_3CHBr.CBr_2CO_2H$ ? [111°]. From  $\alpha$ -bromo-crotonic acid and Br. V. sol. water and alcohol (M. a. N.).

**Tri-bromo-isobutyric acid**  $C_4H_3Br_3O_2$ . From bromo- $\alpha$ -methyl-acrylic acid and Br (Calhoun, A. Suppl. 2, 319). Prisms.

**Tetra-bromo-butyric acid**  $C_4H_2Br_4O_2$ . [115°]. From mucobromic acid and Br (Limpricht, A. 165, 293). Monoclinic tables; sl. sol. water.

**Tetra-bromo-isobutyric acid**  $C_4H_2Br_4O_2$ . From di-bromo- $\alpha$ -methyl-acrylic acid and Br (C.).

**BROMO-ISO-BUTYRIC para-ALDEHYDE**  $((CH_3)_2CBrCHO)_n$ . [129°]. When the product of the action of NH<sub>3</sub> on iso-butyric aldehyde (q. v.) is distilled a product  $C_4H_9N$  is got. This must be combined with bromine, and the compound,  $(CH_3)_2CH.CH.N.CHBr.Br(CH_3)_2$ , after keeping for 3 months, is decomposed by water (Lipp, A. 211, 353). Needles (from alcohol). Insol. water, acids or alkalis, v. sol. ether, m. sol. alcohol. Does not reduce ammoniacal AgNO<sub>3</sub>.

**BROMO-CATECHOL** v. BROMO-PYROGATECHIN.

**BROMO-CAFFEINE**  $C_8H_7BrN_2O_2$ . [206°].

Caffeine combines with Br forming the orange-red bromide  $C_8H_5Br_2N_2O_2$ , which is decomposed at 150° into HBr and bromo-cafeine (Fischer, B. 14, 639; Schultzen, Z. 1867, 614; Maly a. Anbreusch, M. 3, 85). Crystals, sl. sol. cold water, v. sol. NH<sub>4</sub>Aq. Reduced by zinc-dust to caffeine. Alcoholic KOH forms ethoxy-cafeine.

**BROMO-CAMPHOR** v. CAMPHOR.

**BROMO-CAMPHORIC ACID** v. CAMPHORIC ACID.

**BROMO-CAPRIC ACID** v. BROMO-DECOIC ACID.

**BROMO-CAPROIC ACID** v. BROMO-HEXOIC ACID.

**BROMO-CARBANILIC ACID** v. PHENYL-CARBAMIC ACID.

**BROMO-CARBAZOLE**  $C_{12}H_7BrN$ . [199°]. From its acetyl derivative and alcoholic KOH. Rhombic plates, v. sol. water.

*Acetyl derivative*  $C_{14}H_9AcBrN$ . [128°]. From acetyl-carbazole and Br. Laminæ, v. sol. alcohol and boiling toluene (Ciamician a. Silber, G. 12, 276).

**TRI-BROMO-CARBOPIRROLIC ACID** v. TRI-BROMO-PIRROL-CARBOXYLIC ACID.

**$\gamma$ -BROMO-CARBOSTYRIL**  $C_8H_7NOBr$  i.e.

$C(H) \begin{matrix} C(H) \\ | \\ N: \end{matrix} \begin{matrix} C(H) \\ | \\ C(OH) \end{matrix}$ . (Py. 1, 3)-Bromo-oxy-

quinoline. [268°]. Formed by boiling o-amido-phenyl-propionic acid with dilute HBr (Baeyer a. Bloem, B. 15, 2149). Prepared by the action of bromine on carbostyryl-ether and saponification of the product by heating with HCl (Friedländer a. Weinberg, B. 15, 2682). Needles; may be sublimed. The Br is not replaced by boiling with alcoholic KOH, but requires to be fused with KOH at 200°C.

**BROMO-CARVACROL**  $C_{10}H_{11}BrO$  i.e.  $C_6H_5Me(OH)Br(C_2H_5)$  [12:3 or 5:1]. From bromo-cymidine and  $HNO_3$ . Oil (Mazzara, G. 16, 194).

**BROMO-CHLORAL** v. DI-CHLORO-BROMO-ALDEHYDE.

**BROMO-CHLORO-** v. CHLORO-BROMO-

**BROMO-CHLOROFORM** v. DICHLORO-BROMO-METHANE.

**BROMO-DICHROMAZIN** v. TRI-AMIDO-PHENOL, p. 172.

**BROMO-CHRYSENE** v. CHRYSENE.

**BROMO-CHRYSOQUINONE** v. CHRYSO-QUINONE.

**BROMO-CINCHONINE** v. CINCHONINE.

**BROMO-CINNAMENE** v. BROMO-STYRENE.

**DI-BROMO-CINNAMENYL-THIENYL-**

**KETONE** v. THIENYL-DI-BROMO-STYRYL KETONE.

**$\alpha$ -BROMO-CINNAMIC ACID**  $C_9H_7BrO_2$  i.e.  $C_6H_5.CH:CH.Br.CO_2H$  [131°].

*Formation*.—1. Together with *allo-a*-bromo-cinnamic acid by the action of alcoholic KOH on the di-bromide of cinnamic acid  $C_6H_5.CHBr.CHBr.CO_2H$  (Glaser, A. 143, 325).—2. From *exo*-tri-bromo- $\beta$ -phenyl-propionic acid and water at 100° (Kinnicutt a. Palmer, Am. J. 26, 386).

*Preparation*.—Dibromide of cinnamic acid (50 grms.) is dissolved in hot alcohol and mixed with the calculated quantity (2 equivalents) of potash dissolved in alcohol. The liquid is neutralised with HCl and the alcohol boiled off. The solution of the mixed potassium salts is filtered from bromo-styrene [218°]. The two acids are separated by partial precipitation with HCl, the  $\alpha$ -acid coming down first (Barisch, J. pr. 128, 178).

*Properties*. Long needles (from water or chloroform). V. e. sol. alcohol.

*Salts*.— $NH_4A'$ : fluorescent groups of flat needles, sl. sol. cold water.— $AgA'$ : sl. sol. water.— $BaA'_2$ : thin rhombic laminæ. S. 12 at 6°. Insol. alcohol.

*Reactions*.—1. Sodium-amalgam reduces it to  $\beta$ -phenyl-propionic acid.—2. Alcoholic KOH gives phenyl-propionic acid.—3. Br gives a tri-bromo-phenyl-propionic acid [132°].—4. Both  $\alpha$  and *allo-a*-bromo-cinnamic acids may be reduced by zinc-dust and glacial acetic acid to cinnamic acid, which seems to be the same in both cases

(Michael, J. pr. [3] 85, 857).—5. Is not altered by dissolving in  $H_2SO_4$  and pouring into water.

*Methyl ether*  $A'Me$ : (159°) at 14 mm. Formed by distillation of the isomeric methyl ether corresponding to the acid [120°] under ordinary atmospheric pressure (A. a. S.).

*Ethyl ether*  $A'Et$ : (290°); (202°) at 30 mm.; (160°) at 10 mm.; (188°) at 30 mm. V.D. = 8.715 (obs.) (Michael a. Browne, B. 20, 551). Formed by distillation of the isomeric ethyl-ether corresponding to the acid [120°] under ordinary atmospheric pressure (Anschütz a. Selden, B. 20, 1384). Prepared by passing HCl into a solution of the acid in alcohol (4 pts.) (Barisch, loc. cit.). By cold conc.  $H_2SO_4$  it is converted into benzoyl-acetic ether (Michael a. Browne, B. 19, 1392).

*Chloride*: (153°) at 12 mm.; clear oily liquid. Formed by the action of PCl<sub>5</sub> upon salts of the acid [131°] or of its isomeride [120°].

*Amide*: (119°); very thin pearly plates; sl. sol. hot water.

*Anilide*: [80°]; small white needles, which change into six-sided plates (A. a. S.).

*Eco-Bromo-cinnamic acid*  $C_9H_7BrO_2$ . [134°]. Formed, together with the isomeride [159°] by the addition of HBr to phenyl-propionic acid. Long needles (from water). Thick rhombic prisms (from chloroform). V. sol. alcohol and hot benzene, sl. sol. CS<sub>2</sub>, hot petroleum-ether and hot water.— $NH_4^+$ : flat needles, sol. hot water, sl. sol. cold.  $Ag^+$ : glistering rhombic plates; S. 776 at 6°, n. sol. hot water. It is doubtful whether this acid is a distinct isomeride or is identical with the preceding acid; the solubility of the barium salt appears to point to the former conclusion (Michael a. Browne, B. 20, 550).

*Allo-a-Bromo-cinnamic acid*  $C_9H_7.CH:CH.Br.CO_2H$ . [120°]. Formed, together with  $\alpha$ -bromo-cinnamic acid (v. Preparation) by boiling the dibromide of cinnamic acid with alcoholic KOH (Glaser, A. 143, 330). Six-sided laminæ (from water) or thick prisms (from ether). V. sol. boiling water.

*Salts*.— $KA'$ : deliquescent needles.— $AgA'$ . The ammonium salt is deliquescent and v. sol. water (difference from  $\alpha$  acid).

*Reactions*.—1. Reactions 1, 2, and 4 described under  $\alpha$ -bromo-cinnamic acid are also exhibited by the *allo-a* acid. Reaction 3 gives, however, a different tri-bromo-phenyl-propionic acid [45° 48°].—2. On dissolving in  $H_2SO_4$  and pouring into water two products are obtained: (a) A substance  $C_{10}H_9O_4$ ; yellow needles (above 260°), sol. alkalis, alcohol, ether and benzene. (b) A substance  $C_{11}H_9BrO_2$ ; large pearly plates (above 260°), insol. alkalis, sol. phenol, nitrobenzene and aniline, insol. most other solvents, forms a crystalline molecular compound with phenol; on reduction with zinc-dust and acetic acid E gives a substance  $C_{11}H_9O_2$ , which forms colourless crystals, [127°], sol. alcohol, sl. sol. hot water (Leuekart, B. 15, 16).

*Methyl ether*  $A'Me$ : (146°) at 11 mm.; from  $A'Ag$  and MeI; by distillation at ordinary pressure it is converted into the methyl ether of the isomeric acid [131°] (Anschütz a. Selden, B. 20, 1383).

*Ethyl ether*  $A'Et$ : (174°) at 30 mm.; (177°) at 30 mm.; V.D. = 8.828 (obs.) (Michael a.

Browne, *B.* 20, 551). From  $\text{A}^{\circ}\text{Ag}$  and  $\text{EtI}$ . By distillation under ordinary pressure it is converted into the ethyl ether of the isomeric acid [131°] (Anschütz a. Seiden, *B.* 20, 1384).

**$\beta$ -Bromo-cinnamic acid**

$\text{C}_6\text{H}_5\text{Br} \cdot \text{CH} \cdot \text{CO}_2\text{H}$  (?) [159°]. Formed, together with the acid [134°], by the action of aqueous  $\text{HBr}$  upon phenyl-propionic acid at 0°. Long flat needles (from water); or rhombic plates (from alcohol). Sl. sol. cold alcohol and benzene. By cold conc.  $\text{KOH}$  or  $\text{NH}_3$  it is at once converted into an indifferent insoluble oil. Heating with  $\text{HBr}$  forms phenyl-acetic aldehyde and acetophenone. It combines with  $\text{Br}$  forming a tri-bromo-hydro-cinnamic acid [148°].

**Salts.**— $\text{NH}_4\text{A}^{\circ}$ : long soluble needles.— $\text{BaA}^{\circ}_2$ : soluble concentric prisms.— $\text{PbA}^{\circ}_2$ : amorphous pp.— $\text{CdA}^{\circ}_2$ : concentric needles (Michael a. Browne, *B.* 19, 1378).

**Ethyl ether  $\text{A}^{\circ}\text{Et}$ :** (151°) at 15 mm.;  $\text{V.D.}$ —8.948 (obs.) (*M. a. B.*, *B.* 20, 551).

**Bromo-cinnamic acid [153°].** This was obtained by Erlenmeyer a. Stockmeier by the addition of  $\text{HBr}$  to phenyl-propionic acid. Aqueous  $\text{Na}_2\text{CO}_3$  converted it into phenyl-acetylene,  $\alpha$ -bromo-styrene  $\text{C}_6\text{H}_5\text{Br} \cdot \text{CH}$ , and phenyl-propionic acid. Successive treatment with conc.  $\text{H}_2\text{SO}_4$  and water gave benzyl-acetic acid and bromo-acetophenone. Heating with  $\text{HBr}$  gave acetophenone and a little phenyl-acetic aldehyde (Erlenmeyer, *B.* 19, 1336). According to Michael a. Browne this acid is a mixture of the two acids [159°] and [134°].

**$\alpha$ -Bromo-cinnamic acid [1:2]**

$\text{C}_6\text{H}_5(\text{Br}) \cdot \text{CH} \cdot \text{CH} \cdot \text{CO}_2\text{H}$ . **Bromo- $\beta$ -phenyl-acrylic acid.** [213°]. Formed by diazotising  $\alpha$ -amido-cinnamic acid and boiling the diazo-compound with  $\text{HBr}$  (Gabriel, *B.* 15, 2294). Flat colourless needles or scales. Sol. alcohol, ether and acetic acid, sl. sol. chloroform, benzene and  $\text{CS}_2$ .

**$m$ -Bromo-cinnamic acid**

[1:3]  $\text{C}_6\text{H}_4(\text{Br}) \cdot \text{CH} \cdot \text{CH} \cdot \text{CO}_2\text{H}$ . [179°]. Formed like the preceding from  $m$ -amido-cinnamic acid (Gabriel, *B.* 15, 2296). Long needles. Sol. alcohol, acetic acid, hot benzene, chloroform, and  $\text{CS}_2$ .

**$p$ -Bromo-cinnamic acid**

[1:4]  $\text{C}_6\text{H}_4(\text{Br}) \cdot \text{CH} \cdot \text{CH} \cdot \text{CO}_2\text{H}$ . [c. 253°]. Fine needles. From  $p$ -amido-cinnamic acid (Gabriel, *B.* 15, 2300).

**Di-bromo-cinnamic acids  $\text{C}_6\text{H}_3\text{Br}_2 \cdot \text{O}_2$  *is.***  $\text{C}_6\text{H}_3\text{Br}_2 \cdot \text{CH} \cdot \text{CO}_2\text{H}$ . Bromine unites with phenyl-propionic acid producing di-bromo-cinnamic [139°] and allo-di-bromo-cinnamic acid [100°]. The acid [139°] is not converted into an indonaphthene derivative by conc.  $\text{H}_2\text{SO}_4$ , whereas the acid [100°] forms  $\text{C}_6\text{H}_4 \cdot \text{CO} \cdot \text{C}_6\text{H}_4 \cdot \text{Br}$ .

[123°] (whence hydroxylamine forms an oxim [195°]) and aniline forms an anilide [174°] (W. Roser, *B.* 20, 1273, 1376).

**$\alpha$ -BROMO-CINNAMIC ALDEHYDE  $\text{C}_6\text{H}_5\text{Br} \cdot \text{CH} \cdot \text{CH} \cdot \text{CHO}$  [73°].** Formed from cinnamic-aldehyde-di-bromide by splitting off  $\text{HBr}$  (Zincke a. Hagen, *B.* 17, 1815). Thick tables or large monoclinic prisms.  $\text{CrO}_3$  gives bromo-cinnamic acid [131°].

**Phenyl-hydrasine**

$\text{C}_6\text{H}_5 \cdot \text{CH} \cdot \text{CH} \cdot \text{CH} \cdot \text{N} \cdot \text{HC}_6\text{H}_5$  [130°], glistening yellow plates

**BROMO-CITRACONIC ACID  $\text{C}_6\text{H}_7\text{BrO}_4$  *is.*  $\text{CH}_3 \cdot \text{C}(\text{CO}_2\text{H}) \cdot \text{CH} \cdot \text{Br} \cdot \text{CO}_2\text{H}$  (?)**

**Formation.**—1. From its anhydride by boiling with water.—2. From *citra*-di-bromo-pyrotartaric acid, water, and  $\text{Ag}_2\text{O}$  in presence of a trace of  $\text{HCl}$ :  $\text{C}_6\text{H}_7\text{Br}_2\text{O}_6 = \text{HBr} + \text{C}_6\text{H}_7\text{BrO}_4$  (Bourgoin, *C. R.* 88, 342; 89, 418; *A. Ch.* [5] 19, 285).

**Properties.**—Very unstable, giving off water even over  $\text{H}_2\text{SO}_4$  and changing to the anhydride.

**Reactions.**—1. *Sodium anhydride* forms pyrotartaric acid.—2. Boiling  $\text{KOH}$  forms a syrupy dibasic acid  $\text{C}_6\text{H}_7\text{O}_6$ .—3. *Evaporation* of its solution produces bromo-citraconic  $\alpha$ -hydride and, at a low temperature, the acid  $\text{C}_6\text{H}_7\text{O}_6$ , but at a high temperature 'bromo citronic acid'  $\text{C}_6\text{H}_7\text{BrO}_2$  (*B.*).—4. The aqueous solution treated with the equivalent of *aniline* gives a crystalline pp. of the acid anilide  $\text{C}_6\text{H}_7(\text{Br} \cdot \text{CO} \cdot \text{NHPh}) \cdot \text{CONHPh}$  [212°] (Michael, *B.* 19, 1373).

**phenylimide**  $\left\{ \begin{array}{l} \text{CBr} - \text{CO} \\ \text{C}(\text{CH}_3) - \text{CO} \end{array} \right\} \text{NPh}$ . [145°]. This forms stellate groups of prismatic needles. Sl. sol. hot water; v. sol. hot alcohol; in-sol. dilute  $\text{HCl}$  (Michael, *Am.* 9, 180). An intermediate body is the acid anilide  $\text{C}_6\text{H}_7(\text{Br} \cdot \text{CO} \cdot \text{NH}) \cdot \text{CONHPh}$  [212°] (Michael, *B.* 19, 1373).

**Salts.**— $(\text{NH}_4)\text{A}^{\circ}$ .— $\text{KA}^{\circ}$ .— $\text{CaA}^{\circ}_2$  aq.— $\text{CaA}^{\circ}_2$  14aq.— $\text{BaA}^{\circ}_2$  aq.— $\text{Ag}_2\text{A}^{\circ}$ . Decomposed by water at 130° giving off  $\text{CO}_2$  and allylene.

**Anhydride  $\text{C}_6\text{H}_7\text{BrO}_6$ .** [100°]. (220°). *S.G.* 1.935 (Kekulé, *A. Suppl.* 1, 130; 2, 97; Lagermark, *Z.* 1870, 299; Fittig a. Krasenmark, *A.* 206, 19; Bourgoin, *Bl.* [2] 31, 252; 32, 388).

**Formation.**—1. From citraconic anhydride and  $\text{Br}$  at 140°.—2. By distilling *citra*-dibromo-tartaric acid.—3. From pyrotartaric acid,  $\text{Br}$ , and water at 120°. **Properties.** Laminar (from  $\text{CS}_2$ ); sl. sol. cold water, v. c. sol. alcohol and ether; volatile with steam.

**Imide  $\text{C}_6\text{H}_7\text{Br}_2\text{O}_4\text{NH}$ .** [c. 181°]. From pyrotartarimide or citraconimide and  $\text{Br}$  at 150° (Mendini, *G.* 15, 182). Laminar; may be sublimed.— $\text{C}_6\text{H}_7\text{Br}_2\text{O}_4\text{NAg}$ .

**Di-bromo-citraconic acid. Imide.**  $\text{C}_6\text{H}_7\text{Br}_2\text{O}_4\text{NH}$ . [144°]. From pyrotartarimide or citraconimide and  $\text{Br}$  (*M.*). Laminar; may be sublimed.— $\text{C}_6\text{H}_7\text{Br}_2\text{O}_4\text{NAg}$ .

**BROMO-CODEINE *v.* CODEINE.**

**DI-BROMO-COLLIDINE *v.* DI-BROMO-TRIMETHYL-PYRIDINE.**

**BROMO-COMPOUNDS.** Bromine unites directly with most unsaturated compounds, but there are some cases in which it does not combine with them in the cold, *e.g.* fumaric, mesaconic, teraconic, terablenic, aconic, *o*- and *p*-coumaric, and (8)-hydroxypiperic acids (*cf.* Fittig, *A.* 227, 29). Aromatic compounds combine with  $\text{Br}$  with difficulty with bromine, but when reduced to their di- or tetrahydrides they take up bromine as readily as the ordinary unsaturated compounds. Bromine displaces hydrogen in saturated compounds, the displaced hydrogen being given off as  $\text{HBr}$ ; this reaction usually requires the aid of heat; the substance is generally heated with bromine and a little water in a sealed tube.

**Hydroxyl** may be displaced by bromine by treatment with  $\text{HBr}$  or  $\text{PBr}_3$ ; instead of  $\text{PBr}_3$ ,

red phosphorus and bromine may be used, one of the two being added gradually.

**Chlorine** may be displaced by bromine by treatment with the bromide of K, Mg, Ca, Sr, Ba, Al, Mn, or Co (Köhnelein, A. 225, 194).  $\text{CdBr}_2$ ,  $\text{SbBr}_3$ , and  $\text{AsBr}_3$  sometimes act similarly; thus  $\text{AsBr}_3$  at  $115^\circ$  completely converts chloroacetic acid and benzyl chloride into bromoacetic acid and benzyl bromide respectively.

**Iodine** may be displaced by bromine by means of the bromides of Cu, Ag, Hg, Sn, Pb, As, and Sb.  $\text{BiBr}_3$  at  $160^\circ$  only partially converts  $\text{EtI}$  into  $\text{EtBr}$ . Bromine itself can displace iodine (R. Meyer, J. pr. [2] 31, 104).

**Amidogen** may be displaced by bromine by using the diazo-reactions (p. 399). In aromatic compounds it is sufficient to add  $\text{HNO}_3$  to a hot solution of the amine in  $\text{HBr}$  (Losanitsch, B. 18, 39, v. also LAMPERT).

**Carriers.**—The displacement of hydrogen by Br is assisted by the presence of carriers which first combine with the bromine, and then pass it on to the organic body. The most suitable carriers for bromine are: iodine;  $\text{AlBr}_3$  (Gustavson, B. 10, 971) for benzene and homologues; anisophen: P for fatty acids (Hell a. Gantter, B. 14, 891),  $\text{SbBr}_3$ ,  $\text{FeBr}_3$ ,  $\text{FeBr}_2$ , and, better still,  $\text{FeCl}_3$  (Schneidlen, A. 231, 151; cf. Willgerodt, J. pr. [2] 34, 264).

**Bromination of organic acids.** The following is a very convenient method, which depends upon the fact that the acid bromides and anhydrides are much more easily brominated than the acids themselves. The acid is mixed with amorphous phosphorus in quantity sufficient to convert it into the bromide or anhydride, and the corresponding quantity of bromine added together with the extra amount required for bromination. The mixture is heated to  $100^\circ$  till decolourised, when the reaction is complete (Hell, B. 14, 891). The bromination of fatty acids may also be readily effected by boiling their chlorides with Br and  $\text{CS}_2$  (Michael, J. pr. [2] 35, 32). Alkalis or water acting upon  $\alpha$ -bromo-acids usually produce  $\alpha$ -oxy-acids, with  $\beta$ -bromo-acids they form unsaturated acids, while  $\gamma$ -chloro-acids become lactones (Fittig, A. 195, 169; Erlenmeyer, B. 14, 1318; 15, 49).

#### Bromination of aromatic hydrocarbons.

Bromine in presence of a carrier enters the benzene nucleus; bromine alone, or in presence of too little iodine, enters the side-chains of boiling hydrocarbons. Sunlight promotes substitution in the side-chains (Schraumm, B. 17, 2922; 18, 350, 1272; 19, 212).

**Bromination of aromatic amines.** Bromine goes first into a position *p* to the  $\text{NH}_2$ , and then into the *o*-positions, but not into a *m*-position (Neville a. Winther, B. 13, 362; v. also AROMATIC COMPOUNDS, p. 299).

**Stability of bromo-compounds.** Bromo-compounds are less stable than the corresponding chloro-compounds; thus bromoacetic and bromopropionic acids may be converted by reduced silver into succinic and adipic acids respectively, in this they differ from the corresponding chloro- but resemble the iodo-acids. The relative stability of the alkyl bromides depends upon the reagents attacking them; thus Zn and  $\text{H}_2\text{SO}_4$  reduces iso-propyl bromide more quickly than propyl bromide, the order being

isopropyl, isoamyl, butyl, propyl, ethyl; on the other hand, alcoholic  $\text{NaOH}$  attacks propyl bromide more vigorously than isopropyl bromide the order being ethyl, propyl, isoamyl, butyl isopropyl (Remsen a. Hillyer, Am. 8, 251).

Other characteristics of bromo-compounds may be inferred from the article on CHLORO-COMPOUNDS; the bromo-compounds resemble the chloro-compounds in almost every respect.

#### BROMO-CONIINE v. CONIINE.

#### BROMO-COUMARIC ACID $\text{C}_9\text{H}_7\text{BrO}_2$ .

*Bromo-o-oxy-cinnamic acid. Methyl derivative.*  $\text{MeO.C}_6\text{H}_4\text{C}_2\text{H}_3\text{Br.CO}_2\text{H}$ . [ $171^\circ$ ]. S (CS<sub>2</sub>)  $-32$  at  $14^\circ$ . From the methyl derivative of  $\alpha$ - or  $\beta$ -di-bromo-mellilotic acid  $\text{MeO.C}_6\text{H}_3\text{C}_2\text{H}_3\text{Br}_2\text{CO}_2\text{H}$  and aqueous KOH (Perkin, C. J. 33, 422). Small prisms (from CS<sub>2</sub>); sl. sol. boiling water, v. sol. alcohol. Boiling dilute KOH forms the methyl derivative of coumarilic acid  $\text{MeO.C}_6\text{H}_4\text{C}_2\text{CO}_2\text{H}$ .

*Ethyl derivative.*  $\text{EtO.C}_6\text{H}_4\text{C}_2\text{H}_3\text{Br.CO}_2\text{H}$  and cold alcoholic KOH (P.). Flat prisms; sl. sol. boiling water, m. sol. CS<sub>2</sub>, v. sol. alcohol.

( $\alpha$ )-BROMO-COUMARIN  $\text{C}_9\text{H}_6\text{BrO}_2$ . [ $110^\circ$ ]. From coumarin dibromide and alcoholic KOH (Perkin, C. J. 23, 368). Prisms; converted by alcoholic KOH into coumarilic acid.

( $\beta$ )-Bromo-coumarin  $\text{C}_9\text{H}_6\text{BrO}_2$ . [ $160^\circ$ ]. From sodium bromo-o-oxy-benzoic aldehyde and  $\text{Ac}_2\text{O}$ . Rhombic prisms (from alcohol (Perkin, C. J. 24, 37).

( $\alpha$ )-Di-bromo-coumarin  $\text{C}_9\text{H}_4\text{Br}_2\text{O}_2$ . [ $183^\circ$ ]. From coumarin, Br, and I (P.). Needles; alcoholic KOH forms bromo-coumarilic acid.

( $\beta$ )-Di-bromo-coumarin  $\text{C}_9\text{H}_4\text{Br}_2\text{O}_2$ . [ $176^\circ$ ]. From sodium di-bromo-o-oxy-benzoic aldehyde and  $\text{Ac}_2\text{O}$ . Needles (P.).

**BROMO-o-CRESOL**  $\text{C}_7\text{H}_7\text{Br(OH)}$  [ $1:3:7:6$ ] [ $89^\circ$ ]. From bromo-o-toluidine (Wroblewsky A. 168, 165). Golden needles; v. sl. sol. water; the aqueous solution is turned green by  $\text{FeCl}_3$ — $\text{KC}_2\text{H}_3\text{BrO}$  aq: red scales.

**Bromo-m-cresol**  $\text{C}_7\text{H}_7\text{Br(OH)}$  [ $1:3:5$ ] [ $57^\circ$ ]. From *s*-bromo-toluidine by diazo-reaction (Neville a. Winther, C. J. 41, 421).

**Bromo-p-cresol**  $\text{C}_7\text{H}_7\text{(CH}_3\text{)Br.OH}$  [ $1:3:4$ ] [ $214^\circ$ ]. S.G.  $\frac{25}{20} = 1.5468$ . Liquid. Formed by the action of dry bromine upon sodium-*p*-cresol *Methyl ether*  $\text{C}_7\text{H}_7\text{Br(OMe)}$ : [ $226^\circ$ ]. S.G.  $\frac{25}{20} = 1.418$ ; liquid (Schall a. Dralle, B. 17, 2530).

**Di-bromo-o-cresol**  $\text{C}_7\text{H}_5\text{Br}_2\text{(OH)}$ . [ $57^\circ$ ]. From *o*-cresol and Br. Volatile with steam (Werner, B. [2] 46, 278).

**Di-bromo-p-cresol**  $\text{C}_7\text{H}_5\text{(CH}_3\text{)Br}_2\text{OH}$  [ $1:3:5:4$ ] [ $49^\circ$ ]. Large crystals. V. sol. alcohol, v. sl. sol. water. Excess of Br forms  $\text{C}_7\text{H}_3\text{Br}_4\text{(OH)}$  (W.).

*Benzoyl derivative*  $\text{C}_7\text{H}_5\text{Br}_2\text{(OBz)}$  [ $91^\circ$ ], white needles (Schall a. Dralle, B. 17, 2532; Werner, B. [2] 46, 278).

**Tri-bromo-m-cresol**  $\text{C}_7\text{H}_3\text{Br}_3\text{(OH)}$ . [ $82^\circ$ ]. From *m*-cresol (W.). Needles (from alcohol).

**Tetra-bromo-p-cresol**  $\text{C}_7\text{HBr}_4\text{(OH)}$ . [ $109^\circ$ ]. From *p*-cresol (Baumann a. Brieger, B. 13, 804). Plates; slowly decomposed by cold bromine-water into  $\text{CO}_2$  and tri-bromo-phenol.

**BROMO-CRESOL SULPHONIC ACID**  $\text{C}_7\text{H}_6\text{Br(OH)(SO}_3\text{H)}$  [ $1:2$  or  $6:57:3$ ]. From *o*-bromo-toluene by sulphonation, nitration, re-

duction, and diazotisation (Schäfer, A. 174, 361).  
—BaA', 4½ aq.—BaA', 8 aq.—PbA', 2 aq.

**Bromo-cresol sulphonic acid**

$C_6H_4MeBr(OH)(SO_3H)$  [1:4:57:3]. From (3,1,2)-bromo-toluene sulphonic acid by nitration, reduction, and diazotisation (S.).—BaA', 3 aq.

**Bromo-*cr*-sol sulphonic acid**

$C_6H_4MeBr(OH)(SO_3H)$  [1:4:57:2]. From (4,1,2)-bromo-toluene sulphonic acid in a similar way.  
—BaA', aq.

**Di-bromo-cresol sulphonic acid**

$C_6H_2MeBr_2(OH)(SO_3H)$ . From (2,1,4)-amido-toluene sulphonic acid and Br (Hayduck, A. 174, 353).—KA' aq. BaA', 8½ aq.

***α*-BROMO-CROTONIC ACID**  $C_3H_5BrO_2$  i.e.

$CH_3CH:CBBr.CO.H$ . [106:5°].

**Formation.**—1. From *αα*-di-bromo-*n*-butyric acid and alcoholic KOH, NH<sub>3</sub>, baryta-water, or Ag<sub>2</sub>CO<sub>3</sub> (Michael a. Norton, Am. 2, 15; Erlenmeyer a. Müller, B. 15, 49). 2. From *αβ*-di-bromo-butyric ether and alcoholic KOH (Michael a. Browne, Am. 9, 280). 3. Together with bromopyrotartaric acid by the action of bromine on propane tri-carboxylic acid (Blischoff a. Guthzeit, B. 14, 616).

**Properties.**—Long needles (from water); needles (from ligroin); m. sol. cold, v. sol. hot water.—AgA': white needles, quickly affected by light.—BaA', 2 aq.

***Allo-α*-Bromo-crotonic acid**

$CH_3CH:CBBr.CO.H$ . [90°] (K.); [92°] (M. a. N.). From *αβ*-di-bromo-butyric acid (dibromide of crotonic acid) by treatment with alcoholic KOH (Michael a. Norton, Am. 2, 15) or NaOH aq. (C. Kolbe, J. pr. [2] 25, 394).

**Properties.**—Long needles (from water); needles (from ligroin); m. sol. hot water.—AgA': needles, little affected by light.—BaA', 3½ aq.—CaA', 3 aq.

***β*-Bromo-crotonic acid**  $CH_3.CBr.CH.CO.H$ . [95°]. From tetrolic acid and cone. HBr aq. at 0° (Michael a. Browne, Am. 9, 277; J. pr. [2] 35, 258). Flat needles (from water); feathery groups of tough needles (from ligroin); sl. sol. cold water, m. sol. hot water.—AgA': amorphous, readily affected by light.—BaA', aq.—KA'.

***αβ*-Di-bromo-crotonic acid**

$CH_3.CBr:CBBr.CO.H$ . [96°]. From tetrolic acid and Br (Pinner, B. 14, 1081).—Boiling with Ag<sub>2</sub>O gives  $C_3H_5Br_2$ . [116°].

**BROMO-CUMALIC ACID**  $C_6H_4BrO_2(CO.H)$ . [176°]. Formed by the action of bromine on cumalic acid in acetic acid solution (Pechmann a. Welsh, B. 17, 2396). Colourless glistening needles. Can be distilled in small quantities. V. sol. alcohol, ether, acetic acid, and chloroform, more sparingly in benzene, insol. ligroin.

**Methyl ether** AMe: [134°], prismatic needles, sol. alcohol and benzene, sl. sol. ether, insol. water. Aqueous NH<sub>3</sub> converts it into the methyl ether of brom-oxy-nicotinic acid.

***o*-BROMO-*n*-CUMENE**  $C_9H_7Br$  i.e.  $C_6H_4Br.Pr$  [1:2]. **Bromo-*n*-propyl-benzene**. (222 i. v.). A mixture of this body with the *p*-isomeride is formed by the action of Br on propyl-benzene in the dark or on ethyl-benzene mixed with I in diffused daylight (Schramm, P. 18, 1274). KMnO<sub>4</sub> gives *o*-bromo-benzoic acid.

***p*-Bromo-*n*-cumene**  $C_9H_7Br$  [1:4]. (220° cor.) From  $C_6H_5.Pr$  and Br at 0° in presence of I (Meyer a. Müller, B. 15, 698; R. Meyer, J. pr.

[3] 84, 101). HNO<sub>3</sub> (S.G. 1-9) forms *p*-bromobenzoic acid.

***β*-Bromo-*n*-cumene**  $C_9H_7Br$   $CH_2.CH_2$ .

Formed in the cold by the action of bromine (1 mol.) upon *n*-cumene in direct sunshine. By further bromination in sunlight it gives *β*-di-bromo-*n*-cumene  $C_9H_6Br_2.CH_2.CH_2$ , but in the dark at 100° it yields *αβ*-di-bromo-*n*-cumene  $C_9H_6Br_2.CHBr.CH_2$  (Schramm, B. 18, 1275).

***ββ*-Di-bromo-*n*-cumene**  $C_9H_6Br_2$   $CHBr.CHBr.CH_2$ .

From allyl-benzene (*p. v.*) and bromine (Rügheimer, A. 172, 131; Radziszewski, C. R. 78, 1153; Perkin, C. J. 22, 668). From *n*-cumene and bromine at 160° (Wispel, Zuber, A. 218, 381; cf. S. *supra*). Silky needles (from alcohol).

***ββ*-Di-bromo-*n*-cumene**  $C_9H_6Br_2$   $CH_2.CH_2$ .

**Phenyl-ethyl-ketene-di-bromide**. Formed in the cold by the action of bromine (2 mols.) upon *n*-cumene exposed to direct sunshine (Schramm B. 18, 1275).

***ααββ*-Tri-bromo-*n*-cumene**

$C_9H_5Br_3$   $CHBr.CHBr.CH.Br$ . **Stylerin tri-bromhydrin**. [124°]. From cinnamyl bromide and Br, or by the action of HBr on the dibromide of cinnamyl alcohol (Grimaux, R. 20, 129).

**Tetra-bromo-*n*-cumene**  $C_9H_4Br_4$ . Liquid

(Fittig, A. 149, 327).

***o*-Bromo-*n*-cumene**  $C_9H_7Br$  [1:2]. **Bromo-**

**isopropyl-benzene**. (206° cor.) at 740 mm. From isopropyl-phenol and PBr<sub>3</sub> (Fiedt, G. 16, 131).

***p*-Bromo-*n*-cumene**  $C_9H_7Br$  [1:4]. (217°).

S.G. 15 1:3014. Prepared by brominating cumene at 0° in presence of I (Jacobsen, B. 12, 430). With benzene, Na, and CO, it gives cumine acid (R. Meyer, J. pr. [2] 31, 93).

**Penta-bromo-*n*-cumene**  $C_9H_3Br_5$ . [97°]. From

cumene and Br (Moulet, Z. 1867, 322; Fittig, A. 119, 326). Needles; sl. sol. cold alcohol.

**Bromo-*ψ*-cumene**  $C_9H_6Br$   $(CH_3)_2Br$  [1:2:4:5].

[73°]. (237°). White plates.

**Formation.**—1. By the action of cuprous bromide upon diazo-pseudo-cumene (Haller, B. 18, 95). 2. By the action of bromine (1 mol.) in the dark upon pseudo-cumene; the yield is 60 p.c. (Bräntem, A. 137, 323; Fittig, A. 139, 188; 145, 138; Schramm, B. 19, 216; Süssenguth, A. 215, 243). 3. By the action of bromine upon an aqueous solution of pseudo-cumene-sulphonic acid (1:2:4:5) 76 p.c. is converted into bromo-*ψ*-cumene, the remainder forming bromo-*ψ*-cumene sulphonic acid  $C_9H_6Br(SO_3H)$  [1:2:4:5:5] (Kolbe a. Pathe, B. 19, 1547).

**Bromo-*ψ*-cumene**  $C_9H_6Br$   $CH_3.Me.Br$  [1:2:4:3].

(226°-229°). Colourless oil. Formed by the hydrolysis of the sulphonic acid  $C_9H_6Br(SO_3H)$  [1:2:4:3:5], by means of superheated steam at 200°-210°. By MeI and Na it yields *c*-tetramethyl-benzene (Kolbe a. Pathe, B. 19, 1551).

**Bromo-*ψ*-cumene**  $C_9H_6Br$   $CH_3.Me.Br$  [1:2:4:3]. (237°).

Liquid; solid fluid at -15°. Obtained by hydrolysis of the sulphonic acid [1:3:4:5:2]. By sulphonation it is reconverted into the same sulphonic acid (Jacobsen, B. 19, 1223).

***ω*-Bromo-*ψ*-cumene**  $C_9H_6Br$   $(CH_3)_2.CH.Cl$ . **Pseudo-**

**cumyl bromide**. Liquid. Decomposes on distillation. Formed by the action in direct sunshine of 1 mol. of bromine upon 1 mol. pseudo-cumene (Schramm, B. 19, 217).

**Di-bromo-*ψ*-cumene**  $C_9H_4Br_2$   $CH_3.Me.Br_2$  [1:2:4:5:6].

[64°]. (294°). Formed by the action of 1 mol. of bromine upon 1 mol. mono-bromo-pseudo-

cumene by daylight, or in the dark (Schramm, B. 19, 216; Jacobsen, B. 19, 1220). Long flat needles, v. sol. alcohol.

$\alpha$ , $\alpha$ -Di-bromo- $\psi$ -cumene  $C_9H_7(CH_2)(CH_2Br)_2$  [1:2:4]. *Pseudo-cumylene bromide*. [97°]. Flat glistening needles (from petroleum-ether). V. sol. alcohol and benzene. Formed by the action of 2 mols. of bromine upon 1 mol. pseudo-cumene in direct sunshine (Schramm, B. 19, 218; Hjelt a. Gadd, B. 19, 867).

Tri-bromo- $\psi$ -cumene  $C_9H_5Br_3$  [1:2:4:3:5:6]. [226°] or [233° cor.]. V. sol. hot toluene, sl. sol. alcohol. Formed by the action of Br (3 mols.) in the dark upon  $\psi$ -cumene (1 mol.) (Fittig a. Taubinger, A. 151, 264; Schramm, B. 19, 217; Jacobsen, B. 19, 1222).

#### BROMO- $\psi$ -CUMENE-SULPHONIC ACID

$C_9H_7O_3Br(SO_3H)$  [1:2:4:5:6]. [c. 121°]. Formed by dissolving bromo- $\psi$ -cumene [73°] in warm slightly fuming  $H_2SO_4$ . Needles (containing 2aq). By treating the Na salt with zinc-dust and aqueous  $NH_3$ , it is debrominated with production of (1,2,4,6)-pseudo-cumene-sulphonic acid.

Salts. —  $NaA'$  aq. —  $A_2Ca$  3aq. —  $CuA_2$  4aq. —  $BaA_2$  4aq. —  $KA'$  aq.

Amide  $C_9H_7O_3Br(SO_2NH_2)$ : [185°]; small needles, v. sol. alcohol, nearly insol. water (Jacobsen, B. 19, 1218; Kelbe a. Pathé, B. 19, 1553).

#### Bromo- $\psi$ -cumene-sulphonic acid

$C_9H_7O_3Br(SO_3H)$  [1:2:4:5:6]. Formed, together with the di-bromo- acid, by the action of  $ClSO_3H$  upon di-bromo- $\psi$ -cumene. —  $NaA'$  aq.

Amide  $C_9H_7O_3Br(SO_2NH_2)$ : [158°]; thin needles (Jacobsen, B. 19, 1223).

#### Bromo- $\psi$ -cumene-sulphonic acid

$C_9H_7O_3Br(SO_3H)$  [1:2:4:5:6]. [116°]. Colourless needles. Formed by the action of bromine upon an aqueous solution of pseudo-cumene-sulphonic acid [1:2:4:5]; 76 p.c. of the pseudo-cumene-sulphonic acid is converted into bromo-pseudo-cumene [73°], the remainder yielding the bromo-sulphonic acid. It is also formed by sulphonation of bromo-pseudo-cumene [1:2:4:3]. The latter body is formed by the action of superheated steam upon it at 200°–210°.

Salts. —  $NaA'$  aq. —  $KA'$  aq. —  $AgA'$  aq. —  $BaA_2$  aq. —  $PbA_2$  3aq.

Amide  $C_9H_7O_3Br(SO_2NH_2)$ : [188°]; thin needles (Kelbe a. Pathé, B. 19, 1517).

#### Di-bromo- $\psi$ -cumene-sulphonic acid

$C_9H_5Br_2(SO_3H)$  [1:2:4:5:6:3]. Obtained by sulphonation of di-bromo-pseudo-cumene with sulphuric chlorhydric.

Salts. —  $NaA'$  aq. —  $NaA'$  aq. —  $BaA_2$  aq.

Amide  $C_9H_5Br_2(SO_2NH_2)$ : [above 250°]; plates (Jacobsen, B. 19, 1222).

#### BROMO- $\psi$ -CUMENOL

$C_9H_7OBr$  [1:2:4:3:5]. [35°]. Formed by bromination of pseudo-cumenol in cold acetic acid. Slender yellow needles. Insol. water, v. sol. other solvents (Reuter, B. 11, 29; Auwers, B. 18, 2637).

Bromo-iso-cumenol  $C_9H_7Br(OH)$  [2:4:1]. [49°]. *Bromo-isopropyl-phenol*. From *o*-isopropyl-phenol (*o*-isocumenol) and Br (Fileti, G. 16, 117). Decomposes at 250°.

Methyl ether  $C_9H_7PrBr(OMe)$ . (250°).

#### Di-bromo- $\psi$ -cumenol

$C_9H_5Br_2OH$  [1:2:4:3:5:6]. [149°]. Formed by bromination of pseudo-cumenol dissolved in a small quantity of acetic acid. Long colourless

prisms or needles. Insol. water, m. sol. alcohol, acetic acid, and benzene, v. sol. ether.

Methyl ether  $C_9H_7Br_2OMe$ : [96°]. Formed by methylation of the above or by bromination of pseudo-cumenol-methyl ether. White needles. Insol. water, v. sol. other solvents (Auwers, B. 18, 2657).

#### Di-bromo- $\psi$ -cumenol

$C_9H_5Br_2OH$  [1:2:4:3:5:6]. [152°]. From  $C_9H_7OBr_2$  [1:3:4:2:6] (Edler, B. 18, 630; Jacobsen, B. 19, 1220).

#### Di-bromo-iso-cumenol

$C_9H_7PrBr_2(OH)$  [2:4:6:1]. From *o*-iso-cumenol and Br (Fileti). Liquid.

Methyl ether  $C_9H_7PrBr_2(OMe)$ . (279°).  $HNO_3$  forms a nitro-derivative

$C_9H_7PrBr(NO_2)(OH)$  [2:4:6:1]. [33°].

#### BROMO-CUMINIC ACID

$C_{10}H_{11}BrO_2$  i.e.  $C_9H_7Br(C_2H_5)CO_2H$ . [151°]. *Bromo-propylbenzoic acid*. From Br and cuminic acid or silver cuminate (Naquet a. Luginin, Z. 1866, 333; Gerichten, B. 11, 1719). From bromocumene and  $HNO_3$  (Fileti a. Crosa, G. 16, 296).

Neo-bromo-cuminic acid  $C_{10}H_{11}Br(C_2H_5)CO_2H$ . From Br and cuminic acid at 120° (Czumpelik, B. 3, 478).

#### BROMO-CUMYL-BUTYRIC ACID

$C_{13}H_{19}BrO_2$  i.e.  $C_9H_7Pr.C_4H_9.CHBBr.CO_2H$ . [150°]. From cumenyl-crotonic acid and  $HBr$ . Prisms. Decomposed by  $Na_2CO_3$  giving allyl-isopropylbenzene (Perkin, C. J. 32, 662).

#### BROMO-CUMYL-PROPIONIC ACID

$C_{12}H_{17}BrO_2$  i.e.  $C_9H_7Pr.CH_2.CHBBr.CO_2H$ . [87°]. From cumyl-acrylic acid and  $HBr$  (Perkin, C. J. 32, 661). Resolved by boiling water into  $HBr$  and cumyl-acrylic acid.  $Na_2CO_3$  aq forms vinyl-isopropylbenzene.

#### Di-bromo-cumyl-propionic acid

$C_{12}H_{15}Pr.CHBBr.CO_2H$ . [190°]. From cumyl-acrylic acid and Br (Widman, B. 19, 258).

#### BROMO-CUMYL-VALERIC ACID

$C_{14}H_{21}BrO_2$  i.e.  $C_9H_7Pr.C_3H_7.CHBBr.CO_2H$ . From cumenyl-angelic acid and  $HBr$ . Prisms.  $Na_2CO_3$  aq gives isopropyl-butenylbenzene (Perkin, C. J. 32, 663).

#### BROMO-CYANO-BENZENE v. Nitrile of Bromo-benzoic acid.

#### BROMO-*p*-CYMENE

$C_{10}H_7(CH_3)(C_2H_5)Br$  [1:4:2]. *Bromo-p-methyl-n-propylbenzene*. (234° i.v.). S.G. 12° 127.

Formation. — 1. From cymene and Br (Landolph, B. 5, 267). — 2. Together with bromo-*p*-cymene-sulphonic acid  $C_{10}H_7MePr(SO_3H)$  [1:4:5:2] by the action of bromine upon an aqueous solution of *p*-cymene-sulphonic acid (Kelbe a. Koschitzsky, B. 19, 1730). — 3. The same or the following bromo-cymene is formed by hydrolysis of bromo-*p*-cymene-sulphonic acid  $C_{10}H_7MePr(SO_3H)$  [1:4:5:2] (K. a. K.).

Bromo-*p*-cymene  $C_{10}H_7(CH_3)(C_2H_5)Br$  [1:4:3]. (232°). From thymol and  $PBr_3$  (Fileti a. Crosa, G. 16, 287). Formed also by the action of bromine upon an aqueous solution of *p*-cymene-sulphonic acid ( $MePr.SO_3H$  1:4:3) (Claus a. Christ, B. 19, 2165, v. supra).

Di-bromo-*p*-cymene  $C_{10}H_5MeBr_2Pr$ . (272°). S.G. 15° 596 (Claus a. Wimmel, B. 13, 903).

(a). Bromo-*m*-isocymene  $C_{10}H_7MePrBr$  [1:3:6]. (225° cor.). Formed, together with bromo-*iso*-cymene sulphonic acid, by the action of bromine on *m*-isocymene sulphonic acid (Kelbe, A. 210,

46; 255, 261). Oxidised by dilute  $\text{HNO}_3$  to bromo-toluic acid [210°].

(8) **Bromo-isocymene**  $\text{C}_9\text{H}_7\text{Me}(\text{Pr})\text{Br}$  [1:3:4] (224°). Got by distilling  $\text{C}_9\text{H}_7\text{Me}(\text{Pr})\text{Br}(\text{SO}_4\text{K})$  [1:3:4:6] with superheated steam (Kelbe a. Czarnomski, A. 235, 293). Dilute  $\text{HNO}_3$  oxidises it to bromo-toluic acid  $\text{C}_9\text{H}_7\text{MeBrCO}_2\text{H}$  [1:4:3] [153°].

**Di-bromo-m-isocymene**  $\text{C}_{10}\text{H}_8\text{Br}_2$  (273° uncor.). Obtained by brominating (a)-bromo-m-isocymene sulphonic acid (Kelbe a. Czarnomski, A. 235, 281). Converted by fuming  $\text{HNO}_3$  into nitro-bromo-iso-cymene  $\text{C}_{10}\text{H}_7(\text{NO}_2)\text{Br}$  [83°].

**Bromo-p-cymene-sulphonic acid**  $\text{C}_{10}\text{H}_7\text{MePrBr}(\text{SO}_3\text{H})$  [1:4:5:6:2]. **Bromo-p-methyl-n-propyl-benzene sulphonic acid**. Formed, together with bromo-p-cymene  $\text{C}_{10}\text{H}_7\text{MePrBr}$  [1:4:2], by the action of bromine upon p-cymene-sulphonic acid  $\text{C}_{10}\text{H}_7\text{MePr}(\text{SO}_3\text{H})$  [1:4:2] in aqueous solution at 40°–50° (Kelbe a. Koschitzky, B. 19, 1730). Formed also from cymidine by sulphonation and diazotisation (Widman, B. 19, 248). Sodium amalgam reduces it to n-cymene sulphonic acid.

**Salts.**  $\text{KA}^+ \text{aq.}$   $\text{BaA}^+ 2 \text{aq.}$  S. 1 at 17°.— $\text{BaA}^+ 1 \text{aq.}$ — $\text{CuA}^+ 12 \text{aq.}$

**Amide**  $\text{C}_{10}\text{H}_7\text{MePrBr}(\text{SO}_2\text{NH}_2)$ : [152°].

**Bromo-p-cymene-sulphonic acid**

$\text{C}_{10}\text{H}_7\text{MePrBr}(\text{SO}_3\text{H})$  [1:4:2:5]. Formed by sulphonation of bromo-p-cymene [1:4:2] with  $\text{H}_2\text{SO}_4$  (Kelbe a. Koschitzky, B. 19, 1732; Claus a. Christ, B. 19, 2163; Remsen a. Day, Am. 5, 151), or  $\text{ClSO}_3\text{H}$  (Paterno a. Canzoneri, G. 11, 126). Long needles containing 3 aq. (e. 60°). By zinc-dust and  $\text{NH}_4$  it is easily debrominated to p-cymene-sulphonic acid [1:4:5:2].

**Salts.**  $\text{KA}^+ 3 \text{aq.}$ — $\text{PbA}^+ 2$  S. 2:1 at 30°.— $\text{AgA}^+ 4$ — $\text{CaA}^+ 8 \text{aq.}$ — $\text{NaA}^+ 4 \text{aq.}$  (R. a. D.).— $\text{ZnA}^+ 8 \text{aq.}$  (R. a. D.).— $\text{MgA}^+ 9 \text{aq.}$  (R. a. D.).— $\text{CuA}^+ 9 \text{aq.}$  (R. a. D.).— $\text{CaA}^+ 6 \text{aq.}$ — $\text{BaA}^+ 9 \text{aq.}$  (R. a. D.).— $\text{BaA}^+ 5 \text{aq.}$  S. 1:37 at 27°.— $\text{CuA}^+ 8 \text{aq.}$

**Amide**  $\text{C}_{10}\text{H}_7\text{MePrBr}(\text{SO}_2\text{NH}_2)$ : [188°] (K. a. K.) [155°] (C. a. C.).

**Chloride**  $\text{C}_{10}\text{H}_7\text{MePrBrSO}_2\text{Cl}$  [82°].

**Bromo-p-cymene sulphonic acid**

$\text{C}_{10}\text{H}_7(\text{CH}_3)(\text{C}_2\text{H}_5)\text{Br}(\text{SO}_3\text{H})$  [1:4:5:3:2]. [180° uncor.]. Formed by bromination of an aqueous solution of p-cymene-sulphonic acid  $\text{C}_{10}\text{H}_7\text{MePr}(\text{SO}_3\text{H})$  [1:4:3]. Glistening colourless plates (Claus a. Christ, B. 19, 2166).

(a) **Bromo-iso-cymene sulphonic acid**  $\text{C}_{10}\text{H}_7\text{Me}(\text{Pr})\text{Br}(\text{SO}_3\text{H})$  [1:3:6:1]. [165°] and [126°]. From (a)-bromo-iso-cymene by sulphonation, or from (b)-i-cymene sulphonic acid by bromination (Kelbe a. Czarnomski, A. 235, 277). No plates containing 3 aq. (from water). After a week's exposure over  $\text{H}_2\text{SO}_4$  it melts at 126°. **Salts.**— $\text{BaA}^+ 7 \text{aq.}$ — $\text{CuA}^+ 7 \text{aq.}$ — $\text{KA}^+ \text{aq.}$ — $\text{NaA}^+ 2 \text{aq.}$

**Amide**  $\text{C}_{10}\text{H}_7\text{MePrBr}(\text{SO}_2\text{NH}_2)$  [171°].

(b) **Bromo-m-iso-cymene sulphonic acid**  $\text{C}_{10}\text{H}_7\text{Br}(\text{SO}_3\text{H})$  i.e.  $\text{C}_9\text{H}_7\text{Me}(\text{C}_2\text{H}_5)\text{Br}(\text{SO}_3\text{H})$  [1:3:4:6]. [109°]. Formed by bromination of m-isocymene sulphonic acid (Kelbe a. Czarnomski, A. 235, 272). **Salts.**— $\text{PbA}^+ \text{aq.}$ — $\text{BaA}^+ 4$ — $\text{CuA}^+ 4 \text{aq.}$ — $\text{KA}^+ \text{aq.}$

**Amide**— $\text{C}_{10}\text{H}_7\text{Br}(\text{SO}_2\text{NH}_2)$  [162°].

**BROMO-CYMENOL**  $\text{C}_{10}\text{H}_7\text{MePrBr}(\text{OH})$  [1:4:3:2:6]. From amido-cymenol by the diazo-reaction. Oil (Mazzara, G. 16, 191).

**Tri-bromo-cymenol**  $\text{C}_{10}\text{H}_5\text{Me}(\text{C}_2\text{H}_5)\text{Br}_3(\text{OH})$  [2:4:1]. [222°]. Glistening golden plates. Formed by shaking an aqueous solution of

cymenol with a solution of bromine in  $\text{HBr}$  (Jesurun, B. 19, 1414).

**BROMO-CYRIDINE**  $\text{C}_{10}\text{H}_7\text{MeBr}(\text{C}_2\text{H}_5)\text{NH}_2$ . From bromo-nitro-cymene. Liquid (Mazzara, G. 16, 193).

**BROMO-DECANE** v. **DECYL BROMIDE**.

**Di-bromo-decane**  $\text{C}_{10}\text{H}_{18}\text{Br}_2$ . **Decylene bromide**. Oil. From petroleum decylene (Reboul a. Truchot, A. 144, 248).

\* **Di-bromo-decane**  $\text{C}_{10}\text{H}_{18}\text{Br}_2$ . **Diamylene bromide**. From diamylene and  $\text{Br}$  (Bauer, A. 135, 344). Liquid. Alcoholic  $\text{KOH}$  gives rutylene  $\text{C}_{10}\text{H}_{18}$  (150°).

**Tri-bromo-decane**  $\text{C}_{10}\text{H}_{16}\text{Br}_3$ . Oil. From diamylene and  $\text{Br}$  (Valz, Z. 1868, 316). Decomposes at 100°.

**Tetra-bromo-decane**  $\text{C}_{10}\text{H}_{14}\text{Br}_4$ . **Menthene tetrabromide**. From menthene and  $\text{Br}$  (Beckett a. Wright, Report of British Ass. 1875, ii. 88). Oil, split up by distillation into  $\text{HBr}$  and cymene.

**Tetra-bromo-decane**  $\text{C}_{10}\text{H}_{14}\text{Br}_4$ . **Decenylene tetra bromide**. From decenylene (165°) and  $\text{Br}$ . Oil (Reboul a. Truchot, A. 144, 249).

**Tetra-bromo-decane**  $\text{C}_{10}\text{H}_{14}\text{Br}_4$ . From allyl-propylidene propyl-methane (158°) and  $\text{Br}$  (Reformatsky, J. pr. [2] 27, 389).

**DI-BROMO-DECINENES**  $\text{C}_{10}\text{H}_{16}\text{Br}_2$ . Described as hydrobromides of terpenes. V. also **BONSVL BROMIDE**.

**Di-bromo-decylene**  $\text{C}_{10}\text{H}_{16}\text{Br}_2$ . From diamylene and  $\text{Br}$ , p. 211.

**Tetra-bromo-decylene**  $\text{C}_{10}\text{H}_{14}\text{Br}_4$ . **Di-bromo-camphillidene dibromide** [160°–164°]. From camphor and  $\text{PCl}_5\text{Br}$  (De la Royère, Bl. [2] 38, 579). Unctuous tables.

**γ-BROMO-DECOIC ACID**  $\text{C}_{10}\text{H}_{18}\text{BrO}_2$  i.e.  $\text{C}_9\text{H}_{17}\text{CHBr}(\text{CH}_2)_4\text{CO}_2\text{H}$ . From decenoic acid (q. v.) and  $\text{HBr}$  (Schneegans, A. 227, 92). Heavy oil.  $\text{Na}_2\text{CO}_3$  removes  $\text{HBr}$  forming the lactone of oxydecanoic acid.

**Di-bromo-decoic acid**  $\text{C}_{10}\text{H}_{16}\text{Br}_2\text{O}_2$ . **Di-bromocapric acid**. [135°]. From decenoic ('amydecylenic') acid and  $\text{Br}$  (Hall a. Schoop, B. 12, 194). Monoclinic prisms (from benzene).

**DI-BROMO-DECYL ALCOHOL**  $\text{C}_{10}\text{H}_{20}\text{Br}_2\text{O}$ . Oil. From allyl-di-isopropyl-carbinol and  $\text{Br}$  (Lebedinsky, J. pr. [2] 23, 22).

**BROMO-DECYLENE**  $\text{C}_{10}\text{H}_{16}\text{Br}$ . (215°). S.G. 1.21–1.09. Oil. From decylene bromide (v. sup.) and alcoholic  $\text{KOH}$  (Reboul a. Truchot, A. 144, 248). Alcoholic  $\text{FOH}$  forms  $\text{C}_{10}\text{H}_{16}$  (165°) and  $\text{C}_{10}\text{H}_{16}\text{OEt}$ .

**Bromo-decylene** v. **MENTHYL BROMIDE**.

**Di-bromo-decylene**  $\text{C}_{10}\text{H}_{16}\text{Br}_2$ . **Decylene bromide**. Oil. From  $\text{C}_{10}\text{H}_{18}$  and  $\text{Br}$  (R. a. T.).

**Di-bromo-decylene**  $\text{C}_{10}\text{H}_{16}\text{Br}_2$ . From terphenylene hydride and  $\text{Br}$  (Montgolfier, A. Ch. [5] 13, 154).

**Di-bromo-decylene**  $\text{C}_{10}\text{H}_{16}\text{Br}_2$ . From rutylene and  $\text{Br}$  (Bauer, A. 105, 344).

**DI-BROMO-DODECANE**  $\text{C}_{12}\text{H}_{26}\text{Br}_2$  [–15°]. **Dodecylene bromide**. Formed by the addition of  $\text{Br}_2$  to dodecylene (Kraft, B. 17, 1371).

**BROMO-ISO-DURENE**  $\text{C}_{10}\text{H}_7\text{Me}$  [1:3:4:5:6]. (253°). Liquid; solidified by cold (Bielefeldt, A. 198, 388).

**Bromo-s-durene**  $\text{C}_{10}\text{H}_7\text{MeBr}$  [1:2:4:5:3]. [617°]. By bromination of durene (Gissmann, A. 216, 210). Pearly plates (from alcohol).

**Di-bromo-*s*-durene**  $C_{10}H_6Br_2$ , *is.*  $C_6Me_4Br_2$  [1:2:3:4:5:6]. **Di-bromo-*prähnitene***. [210°]. From *s*-durene, Br, and I. Prisms (Jacobsen, *B.* 19, 1218).

**Di-bromo-iso-durene**  $C_{10}H_6Br_2$  [1:3:4:5:2:6]. [209°]. Long fine needles. Sl. sol. hot, v. sl. sol. cold alcohol. Prepared by bromination of iso-durene (Jacobsen, *B.* 15, 1853; cf. Jannasch, *B.* 8, 356).

**Di-bromo-*s*-durene**  $C_6Me_4Br_2$  [1:2:4:5:3:6]. [203°]. Needles (from alcohol) (Fittig a. Jannasch, *Z.* 1870, 161; Friedel a. Crafts, *A. Ch.* [6] 1, 515).

**BROMO-DURENOL**  $C_{10}H_7Br.OH$  [118°]. Formed by bromination of durenol in acetic acid. Long prisms. V. sol. alcohol and ether, insol. water (Jacobsen a. Schnapauß, *B.* 18, 2814).

**DI-BROMO-ENNANE**  $C_9H_7Br_2$ . *Nonylene bromide*. From lh and ennylene (from paraffin). Alcoholic KOH forms bromo-ennylene  $C_9H_5Br$  (c. 210°) (Thorpe a. Young, *A.* 165, 18).

**BROMO-ENNOIC ACID**  $C_9H_7Br.CO_2H$ . From ennoic acid  $C_9H_9O_2$  and HBr. Decomposed by warm aqueous  $Na_2CO_3$  forming an oil, probably  $C_9H_7.C_2H_5$  (Schneegans, *A.* 227, 83).

**BROMO-ENNYLENE** v. **DI-BROMO-ENNANE**.

**BROMO-ERUIC ACID**  $C_{22}H_{39}BrO_2$ . [34°]. From di-bromo-behenic acid and alcoholic KOH. Converted into behenic acid by alcoholic KOH (Haussknecht, *A.* 143, 50).

**Di-bromo-erucic acid**  $C_{22}H_{39}BrO_2$ . [47°]. From behenic acid and bromine (H.).

**BROMO-ETHANE** v. **ETHYL BROMIDE**.

**Di-bromo-ethane** v. **ETHYLENE BROMIDE** and **ETHYLIDENE BROMIDE**.

***u*-Tri-bromo-ethane**  $CHBr_2.CH_2Br$ . **Bromo-ethylene bromide**. (1884) at 752 mm. S.G.  $\frac{173}{4}$  2-6189;  $\frac{175}{4}$  2-6107 (Anschütz, *A.* 221, 138). M. M. 12-897 at 11-7°. From  $CHBr:CH$ , water, and Br (Wurtz, *A. Ch.* [3] 51, 84). Also formed by the action of Br on ethyl bromide, ethylene bromide, or iodo-ethylene (M. Simpson, *P. M.* [4] 14, 544; Caventou, *A.* 120, 323; Tawildaroff, *A.* 176, 22; Stadel, *B.* 11, 1711).

**Reactions.**—1. Alcoholic KOH gives *u*-di-bromo-ethylene, bromo-acetylene, and acetylene. 2. *u*-Di-bromo-ethylene is also formed by the action of alcoholic KOAc, water and  $PhO$ , and  $NaOEt$  (Michael, *Ann.* 5, 192).—3.  $SbCl_5$  gives  $CHCl_2.CH_2I$  (Henry, *Bl.* [2] 42, 262).—4. Benzene in presence of  $Al_2Cl_3$  produces bromo-benzene, *s*-di-phenyl-ethane, and *u*-di-phenyl-ethane (Anschütz, *A.* 235, 333).

***u*-Tetra-bromo-ethane**  $CBr_2.CH_2Br$ . **Acetylide tetra-bromide**. (103-5°) at 13-5 mm. S.G.  $\frac{223}{4}$  2-9216. From  $CBr_2.CH_2$  and Br (Anschütz, *A.* 221, 140; Lennox, *C. J.* 13, 206; Reboul, *A.* 124, 270). Also from tri-bromo-ethane and Br (Donzel, *B.* 12, 2207. Decomposed by heat, giving off Br, and HBr. Converted by benzene and  $Al_2Cl_3$  into *u*-di-phenyl-ethane, and *s*-tetra-phenyl-ethane  $CHPh.CHPh$ . [210°]: bromo-benzene and acetylene dibromide being also formed (Anschütz, *A.* 235, 196).

***s*-Tetra-bromo-ethane**  $CHBr_2.CHBr_2$ . **Acetylene tetra-bromide**. (114°) at 12 mm. S.G.  $\frac{213}{4}$  2-9629. Acetylene, from  $C_2H_2Br$ , and alcoholic KOH is passed directly into bromine. The product, containing  $CHBr_2.CH_2Br$ , is treated with

alcohol and zinc dust and  $CHBr:CHBr$  is separated from  $CH_2:CHBr$  by fractional distillation, and is then mixed with bromine (Anschütz, *A.* 221, 138; cf. Reboul, *C. R.* 54, 1229; Sabanejeff, *B.* 9, 1441; *A.* 178, 112).

**Properties.**—Smells of camphor and chloroform. Takes up moisture from air, becoming cloudy. At 185° it begins to decompose, giving off  $Br_2$  and HBr, and leaving  $C_2HBr_2$ . With water and bromine at 185° it gives  $C_2Br_4$  and  $C_2Br_6$ . Boiling alcoholic KOH forms acetylene and bromo-acetylene. Zinc added to its alcoholic solution forms acetylene dibromide in the cold, but on warming it forms acetylene. With benzene and  $Al_2Cl_3$  it forms bromo-benzene, *u*-di-phenyl-ethane, anthracene, and anthraquinone (Anschütz, *A.* 235, 161).  $Al_2Cl_3$  alone forms  $CHBr_2.CH_2Br$  and  $C_2Br_6$ . Toluene and  $Al_2Cl_3$  give di-methyl-anthracene [225°]. *o*-, *m*- and *p*-xylene appear to give tetra-methyl-anthracenes.

**Penta-bromo-ethane**  $CBr_3.CBr_2H$ . [40°] (S.); [54°] (D.); [57°] (B.). (210°) at 300 mm.

**Formation.**—1. From  $CHBr:CHBr_2$  and Br (Lennox; Sabanejeff, *A.* 216, 241).—2. From bromo-ethylene and Br (Denzel, *B.* 12, 2208).—3. From bromo-acetylene and Br (Reboul, *A.* 124, 268).—4. By spontaneous decomposition of tri-bromo-ethylene exposed to air (Demole, *Bl.* [2] 34, 204).—5. From acetylene tetrabromide and Br (Bourgoin, *Bl.* [2] 23, 173).—6. From succinic acid, water, and Br (Orlovsky, *J. R.* 9, 280).

**Hexa-bromo-ethane**  $CBr_6$ . **Carbon hexabromide**. Formed by brominating  $C_2Br_4H$  (Reboul). Formed also by the action of Br and Al on  $CCl_4$ ,  $C_2Cl_4$ , or  $C_2Cl_6$  (Gustavson, *J. R.* 13, 287). Also from micobromic acid, water, and Br at 130° (Delbrück, *A.* 165, 253). Prisms (from  $CS_2$ ); insol. alcohol. At 200°-210° it decomposes, without previous fusion, into Br and  $C_2Br_4$ . Unlike the latter, it is not volatile with steam.

**BROMO-ETHENYL-NAPHTHYLENE-DIAMINE**

[229°]. Formed by reduction of the acetyl derivative of (1:3:4)-bromo-nitro-( $\alpha$ )-naphthylamine with  $SnCl_2$ . Small white needles. V. sol. alcohol and ether, insol. water. The ethenyl group is very stable. Salts.— $BHCl$ .— $BH_2SO_4$ .— $BHNO_2$ : fine white sparingly soluble needles. (Prager, *B.* 18, 2160; cf. Meldola, *C. J.* 47, 505).

**BROMO-ETHOXY-** v. **BROMO-OXY-**.

**BROMO-ETHYL-ACETO-ACETIC ETHER** v. **BROMO-ACETO-ACETIC ETHER**.

**$\alpha$ -Bromo-ethyl-aceto-acetic-ether**  $C_6H_5BrO$ , *is.*  $CH_3.CO.CH(CO_2Et).CH_2Br$ . Heavy yellowish oil of camphor-like odour. Not distillable. Formed by dissolving trimethylene-methyl-

three times its weight of strongly cooled conc. HBr (1-85 S.G.), allowing to stand 10 mins. at 15° and pouring into iced water. By boiling

with HCl it is converted into acetyl propyl alcohol  $\text{CH}_3\text{COOCH}_2\text{CH}_2\text{CH}_2\text{OH}$  (v. p. 46) with formation of alcohol,  $\text{CO}_2$ , and HBr (Perkin, jun., a. Freer, *C. J.* 51, 833, *B.* 19, 2565).

**BROMO-ETHYL ALCOHOL** v. GLYCOL BROM-HYDRIN.

**Dibromo-ethyl alcohol**  $\text{CHBr}_2\text{CH}_2\text{OH}$ . (180°). S.G.  $\rho$  2.35. From bromo-ethylene and dilute HBrO (Demole, *B.* 9, 49). Reduces ammoniacal  $\text{AgNO}_3$ . Alcoholic KOH gives bromo-ethylene oxide. *Acetyl derivative*  $\text{CHBr}_2\text{CH}_2\text{OAc}$ . (194°). S.G.  $\rho$  1.98.

**BROMO-TRI-ETHYL-AMINE**. *Ethylbromide*  $\text{C}_2\text{H}_5\text{Br}$ ,  $\text{NEt}_3$ , Br. From  $\text{NEt}_3$  and ethylene bromide. Alcoholic KOH forms  $\text{C}_2\text{H}_5\text{NEt}_2\text{Br}$  (Hofmann, *C. R.* 49, 880).

**p-BROMO-ETHYL-ANILINE**  $\text{C}_6\text{H}_4\text{BrNH}_2$ . From p-bromo-aniline and EtBr (Hofmann, *A.* 74, 145).

**p-Bromo-di-ethyl-aniline**  $\text{C}_6\text{H}_4\text{BrNEt}_2$ . (33°). (270°). Needles or prisms. Formed by bromination of diethylaniline (Claus a. Howitz, *B.* 17, 1327).

**p-BROMO-ETHYL-BENZENE**  $\text{C}_6\text{H}_4\text{BrEt}$ . [14]. (204°). S.G.  $\rho$  1.34. From p-ethylbenzene, Br, and I (Kokulé a. Thorpe, *C. J.* 22, 866). From  $\text{C}_6\text{H}_5\text{Br}$ , EtI, and Na (Aschenbrandt, *A.* 216, 222). Does not solidify at -20°. A mixture of o- and p-ethylbenzenes is formed by the action of bromine in the dark upon ethylbenzene, or by the action of bromine in presence of 3 p. c. of iodine upon ethylbenzene in diffused daylight (Schramm, *B.* 18, 1272).

**o-Bromo-ethylbenzene**  $\text{C}_6\text{H}_4\text{CH}_2\text{CH}_2\text{Br}$ . (c. 148°) at 30 mm. S.G.  $\rho$  1.311. Formed by direct combination of styrene with HBr (Berntsen a. Bender, *B.* 15, 1983). Formed also by treating a mixture of benzene and bromo-ethylene with  $\text{AlCl}_3$  (Hanriot a. Guilbert, *C. R.* 98, 525).

**a-Bromo-ethylbenzene**  $\text{C}_6\text{H}_5\text{CHBrCH}_3$ . (87°) at 17 mm. (c. 150°) at 500 mm. From Br and ethylbenzene at 140° (Radziszewski, *B.* 6, 492; Berthelot, *C. R.* 67, 328; Anschütz, *A.* 235, 328). Formed also by passing HBr into cooled phenyl-methyl-carbinol (Engler a. Bethge, *B.* 7, 1125). Partially decomposed by distillation into styrene and HBr.

**o-a-Di-bromo-ethylbenzene**  $\text{Ph.CHBr.CH}_2\text{Br}$ . (74°). (140°) at 15 mm. *Styrene di-bromide*.

**Preparation**.—1. From styrene (10 g.), ether (25 g.) and bromine (17 g.) (Blyth a. Hofmann, *A.* 53, 306; Zincke, *A.* 218, 288).—2. From hot ethylbenzene and Br (Radziszewski, *B.* 6, 493; Friedel a. Balson, *Bl.* [2] 35, 55).

**Properties**.—White plates or needles (from 80 p. c. alcohol). V. c. sol. ether, benzene and glacial HOAc, v. sol. alcohol or benzoline.

**Reactions**.—1. KOAc and alcohol at 160° gives chiefly  $\beta$ -bromo-styrene (150°-160° at 75 mm.).—2. KOAc and glacial HOAc gives chiefly the diacetate of phenyl-glycol,  $\text{Ph.CH(OAc)CH}_2\text{(OAc)}$ .—3. Alcoholic KOH or water at 190° give  $\alpha$ -bromo-styrene (Glaser, *A.* 154, 154).—4. Gives  $\text{PhCH(OH)CH}_2\text{(OH)}$  by treatment with  $\text{AgOAc}$ , alcohol and 1 AgOBz, or aqueous  $\text{K}_2\text{CO}_3$ . AgOBz in presence of toluene forms  $\text{Ph.CH(OBz)CH}_2\text{(OBz)}$ .—5. Benzene and  $\text{AlCl}_3$  give  $\alpha$ -di-phenyl-ethane (Anschütz, *A.* 235, 328).

**Tri-bromo-ethylbenzene**  $\text{C}_6\text{H}_3\text{CHBr}_2\text{CH}_2\text{Br}$ . (38°). From  $\alpha$ -bromo-styrene and Br (Fittig a. Binder, *A.* 195, 142). Acted upon by benzene and  $\text{AlCl}_3$  in presence of  $\text{CS}_2$ , it is converted into  $\alpha$ -tetra-phenyl-ethane [209°] (A.).

**Tetra-bromo-ethylbenzene**  $\text{C}_6\text{H}_2\text{Br}_4$ . From di-bromo-ethylbenzene and Br (Kinnicutt a. Palmer, *Am.* 5, 387).

**Penta-bromo-ethylbenzene**  $\text{C}_6\text{HBr}_5$ . From ethylbenzene, Br, and  $\text{AlBr}_3$  (Gastavsen, *Bl.* [2] 30, 22).

**Di-bromo-di-ethylbenzene**  $\text{C}_6\text{H}_2(\text{C}_2\text{H}_5\text{Br})_2$ . (200°-230°) at 30 mm. From bromo-ethylene, benzene, and  $\text{AlCl}_3$  (Hanriot a. Guilbert, *C. R.* 98, 525).

**Bromo-tetra-ethylbenzene**  $\text{C}_6\text{H}(\text{C}_2\text{H}_5)_3\text{Br}$ . (284° uncor.). Heavy liquid (Galle, *B.* 16, 1745).

**Di-bromo-tetra-ethylbenzene**  $\text{C}_6(\text{C}_2\text{H}_5)_4\text{Br}_2$ . (75°). (above 330°). Prisms. V. sol. alcohol (Galle, *B.* 16, 1745).

**BROMO-ETHYL-BROMIDE** v. Di-BROMO-ETHANE.

**BROMO-ETHYL BROMO-ACETATE** v. BROMO-ACETIC ACID.

**BROMO-ETHYLENE**  $\text{C}_2\text{H}_2\text{Br}_2$  i.e.  $\text{CHBrBrCH}_2$ . *Vinyl bromide*. (16°). S.G.  $\rho$  1.5167 (Anschütz). Formed by the action of alcoholic KOH upon either di-bromo-ethane (Regnault, *A.* *Ch.* [2] 59, 358; Beilstein, *J.* 1861, 609; Glöckner, *A. Suppl.* 7, 109; Semenov, *J.* 1861, 480). Formed also from acetylene and HBr (Reboul, *C. R.* 74, 917). Gas or liquid; when kept in a sealed tube and exposed to sunlight it changes to an amorphous polymeride, insol. water, alcohol, and ether; S.G. 2.075. This substance carbonises when heated (Hofmann, *C. J.* 13, 68; Baumann, *A.* 163, 308); it is not affected by boiling alcoholic KOH. Polymerisation is arrested by the presence of MeI or EtI, but not by chlorinated or brominated hydrocarbons; a little I stops polymerisation of the liquid, but not of the gas. An line arrests, but  $\text{SO}_2$  promotes, the change (Lwow, *Bl.* [2] 35, 169).

**Reactions**.—1. Split up into HBr and acetylene by alcoholic KOH,  $\text{NaOEt}$ ,  $\text{NaOC}_2\text{H}_5$ , or ammoniacal  $\text{AgNO}_3$  (Sawitsch, *Bl.* 1861, 7; *A.* 119, 185; Miasnikoff, *Bl.* 1861, 12; *A.* 118, 330).—2. Conc. HBr at 62° forms  $\alpha$ -di-bromo-ethane; a more dilute acid gives  $\alpha$ -di-bromo-ethane (Reboul, *A.* 155, 29, 212).—3. Fuming HCl at 100° forms  $\text{CH}_2\text{CHBrCl}$ .—4. Conc. HI at 4° gives  $\text{CH}_3\text{CHBrI}$ ; at 100° it forms also  $\text{CH}_2\text{I.CH}_2\text{I}$  (R.).—5. Aqueous solutions of metallic salts either have no action or split it up into acetylene and HBr (Kutscheroff, *B.* 14, 1532; Linnemann, *A.* 143, 347; Saytzeff a. Glinsky, *Z.* [2] 3, 675).—6. Successive treatment with conc.  $\text{H}_2\text{SO}_4$  and water forms crotonic aldehyde (Zincke, *A.* 191, 379).—7. Aqueous BrOH at 0° gives  $\text{CHBr.CH(OH)CH}_2\text{CH}_2\text{Br}$ , and  $\text{C}_2\text{H}_2\text{Br}_2$  [40°-45°-90°] (Demole, *B.* 9, 49).—7. Dry oxygen at 23° has no action.—8. ICl forms  $\text{CHBrICH}_2\text{Cl}$  and a less quantity of  $\text{CHI.CHBrCl}$  (Henry, *C. R.* 98, 680).—9. With benzene and  $\text{AlCl}_3$  it produces styrene, ethylbenzene,  $\alpha$ -di-phenyl-ethane, and di-methyl-anthracene dihydride (Anschütz, *A.* 235, 331). If elevation of temperature be avoided and the  $\text{AlCl}_3$  be slowly added the products are  $\text{C}_6\text{H}_5\text{C}_2\text{H}_2\text{Br}$  and  $\text{C}_6\text{H}_4(\text{C}_2\text{H}_2\text{Br})_2$  (Hanriot a. Guilbert, *C. R.* 98, 525).

***s*-Di-bromo-ethylene**  $\text{CHBr:CHBr}$ . *Acetylene dibromide*. (110°–111°). S.G.  $\frac{17.5}{4}$  2-2714 (Anschütz, A. 221, 141);  $\frac{2}{2}$  2-268 (Sabaneff, B. 9, 1441; Plimpton, C. J. 39, 536);  $\frac{12}{12}$  2-223 (S.). V.D. 6:47 (calc. 6:44).—Formed by mixing acetylene tetrabromide (100 g.) with alcohol (20 g.) and adding zinc dust slowly, with cooling (A.; cf. Sabaneff, A. 216, 252).

*Properties*.—Oil; does not polymerize.

*Reactions*.—1. Heated for several days with 50 pts. of water at 135°, it is not affected.—2. Heated with dilute  $\text{K}_2\text{CO}_3$ , bromo-acetylene is formed, which is spontaneously inflammable. Alcoholic  $\text{KOH}$  and aqueous  $\text{KCy}$  also form bromo-acetylene.—3. Heated with dry  $\text{KOAc}$  at 160° for two days it forms  $\text{CHBr:CH(OAc)}$ , the acetate of bromo-vinyl alcohol (Sabaneff, *Bl.* [2] 41, 253).—4. Heated with  $\text{AgOAc}$  and a little  $\text{HOAc}$  at 100° it forms a compound  $\text{C}_2\text{H}_2\text{Br}_2\cdot 2\text{AgOAc}$ . This is decomposed by  $\text{HCl}$  with evolution of acetylene.—5. Combines with  $\text{AgNO}_3$ .—6. With alcoholic  $\text{KCN}$  it forms a compound which, on saponification, gives an acid  $\text{C}_2\text{H}_2\text{O}_4$  (163°–168°). Its silver salt is  $\text{C}_2\text{H}_2\text{Ag}_2\text{O}_4$  (S.).—7. Alcoholic  $\text{KOPh}$  gives  $\text{CHBr:CHOPh}$  (c. 223°); S.G.  $\frac{12}{12}$  1-485.—8. With alcoholic  $\text{NMe}_3$  at 120° it forms  $\text{NMe}_2\text{Br}$ ,  $\text{NMe}_2\text{HBr}$ ,  $\text{NMe}_2\text{I}_2\text{Br}$ , and carbonaceous bodies:  
 $2\text{NMe}_3 + \text{C}_2\text{H}_2\text{Br}_2 = 2\text{NMe}_2\text{HBr} + \text{C}_2$

(Plimpton, C. J. 39, 536).—9. With  $\text{NEt}_3$  it acts similarly.—10. Acts upon benzene in presence of  $\text{AlCl}_3$  forming  $\text{CHBr}_2\text{CH}_2\text{Br}$ , anthracene, and  $\text{CH}_2\text{Ph:CH}_2\text{Ph}$  (Anschütz, A. 235, 153).

***u*-Di-bromo-ethylene**  $\text{CBr}_2\text{CH}_2$ . *Acetylidene dibromide*. (92°) at 751 mm. in  $\text{CO}_2$ . S.G.  $\frac{29.6}{4}$  2-1780 (Anschütz). From  $\text{CHBr}_2\text{CH}_2\text{Br}$  by treatment with alcoholic  $\text{KOH}$ ,  $\text{NaOEt}$ , sodium, or solid  $\text{KOH}$  (Cahours, C. R. 31, 293; Fontaine, C. R. 70, 1361; Sawitsch, A. 119, 183; Reboul, A. 124, 270; Tawildaroff, A. 176, 22; Michael, *Ann.* 5, 192). From  $\text{CBr}_2\text{CH}_2\text{Br}$  by boiling with alcohol and  $\text{KOAc}$  (Demole, *Bl.* [2] 29, 205), or by treatment with zinc and alcohol (Sabaneff, A. 216, 255). Also from  $\text{CH}_2\text{ClCHBr}_2$  and alcoholic  $\text{KOH}$  (Henry, *Bl.* [2] 42, 262).

*Properties*.—Pungent liquid, attacking the eyes. Readily absorbs oxygen, changing to bromo-acetyl bromide. Polymerises with great ease, becoming solid.

*Reactions*.—1.  $\text{HBrO}$  forms  $\text{CBr}_2\text{CO:CH}_2\text{CBr}_2$  [90°]. S.G.  $\frac{2}{2}$  2-88 (Demole, B. 11, 1710).—2. Benzene and  $\text{AlCl}_3$  give *u*-di-phenyl-ethylene (Anschütz, A. 235, 158).

**Tri-bromo-ethylene**  $\text{CHBr:CBBr}_2$ . (163°–164°). S.G.  $\frac{29.5}{4}$  2-708 (S. a. D.);  $\frac{2}{2}$  2-69 (Demole, B. 11, 318). From di-bromo-ethylene bromide and alcoholic  $\text{KOH}$  (Lennox, A. 122, 125).

*Preparation*.—Acetylene tetra-bromide (1 mol.) is dissolved in twice its weight of alcohol and (somewhat more than 2 mols. of)  $\text{KOAc}$  and  $\text{Na}_2\text{CO}_3$  (1 mol.) are added; the mixture is heated on a water bath 24 hours with inverted condenser (Sabaneff a. Dworakowitsch, A. 216, 280; cf. Sabaneff, A. 178, 122; *Bl.* [2] 29, 207).

*Reactions*.—1. Alcoholic  $\text{KOH}$  or  $\text{Zn}$  and  $\text{HOEt}$  give a mixture of  $\text{C}_2\text{H}_2$  and  $\text{C}_2\text{H}_2\text{Br}$ .—2. Alcoholic  $\text{KOPh}$  at 100° forms phenyl di-bromo-vinyl oxide.—3. Alcoholic  $\text{KOPh}$  at 170° forms the phenyl derivative of glyoxylic acid,

$\text{PhO:CH}_2\text{CO}_2\text{H}$ .—4. Reacts upon benzene in presence of  $\text{AlCl}_3$  producing *u*-di-phenyl-ethylene and tri-phenyl-methane (Anschütz, A. 235, 336).—5. Absorbs oxygen, becoming  $\text{CHBr}_2\text{CO}_2\text{Br}$  (Demole a. Dün, B. 11, 1802).

**Tri-bromo-ethylene** ( $\text{C}_2\text{HBr}_3$ ). [174°]. A by-product in formation of  $\text{C}_2\text{H}_2\text{Br}_2$  from acetylene (Sabaneff, A. 178, 114).

**Tetra-bromo-ethylene**  $\text{C}_2\text{Br}_4$ . [54°]. (215°).

*Formation*.—1. By the action of  $\text{Br}$  on alcohol or ether (Löwig, A. 3, 292).—2. From  $\text{C}_2\text{HBr}_2$  and alcoholic  $\text{KOH}$  (Lennox, A. 122, 126).—3. From  $\text{CH}_2\text{Cl}_2$  and  $\text{I}_2$  (Höland, A. 210, 234).—4. From  $\text{CBr}_4$  by heating at 220° (11.).—5. From di-bromo-succinic acid,  $\text{Br}$ , and water at 190° (Bourgois, B. 7, 1644).

*Properties*.—Plates; volatile with steam; no. affected by oxygen even at 216° (D.).

**BROMO-ETHYL-ETHER** v. **BROMO-ETHYL OXIDE**.

**BROMO-ETHYL-KAIRINE** v. **Ethyl ether of Bromo-(B. 4)-oxy-(B. 4)-ethyl-quinoline tetrahydride**.

**$\gamma$ -BROMO-ETHYL-MALONIC ACID**

$\text{C}_2\text{H}_2\text{BrO}_2$ , i.e.  $\text{Br:CH}_2\text{CH}_2\text{CH(CO}_2\text{H)}_2$ . [116°]. From vinaconic (tri-methylene di-carboxylic) acid and  $\text{HBr}$  (Röder, A. 227, 19; Perkin, jun., C. J. 47, 814). Sl. sol. benzene,  $\text{CS}_2$  or light petroleum, sol. chloroform. Boiled with water it gives the lactone of  $\gamma$ -oxy-ethyl-malonic acid (*q. v.*).

**Bromo-ethyl-malonic acid**

$\text{CH}_2\text{CHBrCH(CO}_2\text{H)}_2$  (?). [141°]. From crotaconic acid  $\text{C}_3\text{H}_3\text{O}_4$  and  $\text{HBr}$  (Claus, A. 191, 79).

**TRIBROMO-( $\alpha$ )-ETHYL-NAPHTHALENE**

$\text{C}_{10}\text{H}_7\text{Br}_3\text{C}_2\text{H}_5$ . [127°]. Slender needles. Prepared by the action of bromine on ( $\alpha$ )-ethyl-naphthalene (Carnelutti, B. 13, 1622).

**BROMO-ETHYL ( $\beta$ )-NAPHTHYL ETHER** v.

( $\beta$ )-NAPHTHOL.

***iso*-BROMO-DI-ETHYL OXIDE**

$\text{CH}_3\text{BrCH}_2\text{OEt}$ . (128°). S.G.  $\frac{2}{2}$  1-371. V.D. 5:29 (calc. 5:28). From the iodo-compound and  $\text{Br}$  (Henry, C. R. 100, 1007).

**Di- $\omega$ -bromo-di-ethyl oxide**  $\text{CH}_2\text{BrCHBrOEt}$ . From  $\text{Br}$  and vinyl ethyl oxide. Very unstable liquid.  $\text{NaOEt}$  gives  $\text{CH}_2\text{BrCH(OEt)}_2$  (Wislizenus, A. 192, 111).

**Tetra-bromo-di-ethyl oxide**  $\text{C}_2\text{H}_2\text{Br}_4\text{O}$ . A fuming liquid obtained by saturating ethylidene oxychloride with  $\text{Br}$  at 120° (Kessel, B. 10, 1667).

**Octo-bromo-di-ethyl oxide**  $\text{C}_2\text{H}_2\text{Br}_8\text{O}$  (c. 134°) at 160 mm. By heating ethylidene oxychloride with  $\text{Br}$  for 10 hours from 100°–210° (Kessel, B. 10, 1667). Fuming oil.

**Eso-*exo*-DI-BROMO  $\alpha$ -ETHYL-PHENOL**

$\text{C}_6\text{H}_4\text{Br(C}_2\text{H}_5\text{)OH}$ . From  $\alpha$ -ethyl-phenol and  $\text{Br}$  in the cold. Decomposed by distillation into  $\text{HBr}$  and  $\text{C}_6\text{H}_4\text{Br(C}_2\text{H}_5\text{)OH}$  (Suida a. Plohn, M. 1, 175).

**Tri-bromo-( $\alpha$ )-ethyl-phenol**  $\text{C}_6\text{HBr}_3\text{EtOH}$ . [55°]. Formed, together with the following body, by treating ( $\alpha$ )-ethyl phenol with excess of  $\text{Br}$  in the cold (Fittig a. Kiesow, A. 156, 251).

**Eso-*exo*-Tri-bromo-ethyl phenol**

$\text{C}_6\text{H}_3\text{Br}_3\text{(OH)CHBr:CH}_2\text{Br}$ . [108°]. Long white needles. Obtained by the action of alcoholic  $\text{KOH}$  upon  $\text{C}_6\text{H}_4\text{Br(OH)CHBr:CHBrCO}_2\text{H}$ , the product of the action of bromine upon *p*-coumaric acid.

**Acetyl derivative**  $C_6H_4Br(OAc).C_6H_4Br$ : [94°]; needles (Eigel, B. 30, 2535).

**Tetra-bromo-ethyl phenol**  $C_6Br_4Et.OH$  [106°] (v. sup.).

**BROMO-TETRA-ETHYL-PHOSPHONIUM BROMIDE**  $CH_3Br.CH_2.PEt_3.Br$ . [235°]. From  $PEt_3$  and ethylene bromide in the cold (Hofmann, Pr. 9, 287; A. Suppl. 1, 154). Rhombic dodecahedra.

**Reactions.**—1. Moist silver oxide gives  $CH_3(OH).CH_2.PEt_3.OH$  (difference from corresponding derivatives of  $AsEt_3$  and  $NEt_3$ , which give vinyl base).—2. With silver acetate and water at 100° it gives acetate of the vinyl base  $C_2H_5.PEt_3.OAc$ .—3. Zinc and  $H_2SO_4$  give tetra-ethyl-phosphonium bromide.—4. Alcoholic potash has no effect.—5. Combines with  $PEt_3$ ,  $AsEt_3$  and  $NH_3$  forming di-acid bases.

**Salts.**— $(C_2H_5.Br.PEt_3.Cl).PtCl_6$ . Palo orange monoclinic prisms, sl. sol. cold, v. sol. hot, water.— $(C_2H_5.Br.PEt_3.Cl)AuCl_4$ .— $C_2H_5.Br.PEt_3.I$ .

**Hydrosulfide.**— $C_2H_5.Br.PEt_3.OH$ . From the sulphate by the action of baryta. Unstable, rapidly changing to  $C_2H_5.OH.PEt_3.OH$ .

#### BROMO-ETHYL-QUINOLINE

$C_8H_7(C_2H_5.Br)N$ . The hydrobromide is formed by heating quinoline with ethylene bromide.— $B.HBr$ : thick needles.— $(B.H.Cl).PtCl_6$ : orange-yellow needles (Berend, B. 14, 1349).

#### DI-BROMO-DI-ETHYL SULPHATE

$(CH_3Br.CH_2)_2SO_4$ . An oil formed by warming  $Ag_2SO_4$  with benzene and ethylene bromide (Beilstein u. Wiegand, B. 15, 1369).

#### Bromo-ethyl-sulphuric acid

$CH_3Br.CH_2.O.SO_3H$ . From ethylene bromide and  $SO_3$  (Wroblewski, Z. 1868, 563).  $BaX_2$ .— $PbA_2$  3aq, scales. An isomeric acid appears to be formed by heating ethylene bromide with  $Ag_2SO_4$  and water (B. a. W.).

#### BROMO-ETHYL-THIOPHENE

$C_6H_4(C_2H_5.Br)$ . [195° uncor.]. Oil. Formed by shaking ethyl-thiophene with bromine-water (Demuth, B. 19, 684).

**Di-bromo-( $\beta$ )-ethyl-thiophene**  $C_6SHBr_2(C_2H_5)$ . Oil. Formed by adding 2 mols. of bromine to 1 mol. of ( $\beta$ )-ethyl-thiophene dissolved in acetic acid (Bonz, B. 18, 550).

**Tri-bromo-( $\beta$ )-ethyl-thiophene**  $C_6SBr_3(C_2H_5)$ . [108°]. White plates. Sl. sol. cold alcohol and ether. Formed by complete bromination of ( $\beta$ )-ethyl-thiophene (Bonz, B. 18, 549).

**BROMO-o-ETHYL-TOLUENE**  $C_8H_7MeEtBr$  [1:2:4]. (221°). Formed by bromination of o-ethyl-toluene in presence of  $Fe.Br_3$ . Liquid. By  $HNO_3$  (1:1) at 200° it is oxidised to p-bromo-o-toluic acid [118°] (Claus u. Pieszeck, B. 19, 3088).

**Bromo-p-ethyl-toluene**  $C_8H_7MeEtBr$  [1:2:4]. From p-ethyl-toluene and  $Br$ . Oxidised to bromo-p-toluic acid (Morse u. Reinsen, B. 11, 224).

#### o-Di-bromo-m-ethyl-toluene

$C_8H_7.CHI.Br.CH_3.Br$ . [15°]. Formed by the combination of m-tolyl-ethylene (m-methylstyrene) with bromine. Colourless crystals (Müller, B. 20, 1216).

**Tri-bromo-di-ethyl-toluene**  $C_8Br_3MeEt$ . [206°]. From (1, 3, 5)-di-ethyl-toluene (Jacobsen, B. 7, 1435).

**TRI-BROMO-ETHYL-XYLENE**  $C_8Br_3EtMe_2$  [8:5:0:1:2:4]. **Tri-bromo-di-methyl-ethyl-benz-**

**ene**. [91°]. From ethyl-m-xylene (187°) (Anschütz, A. 235, 824).

**BROMO-EUGENOL**  $C_9H_7Br(OMe)(OH).C_6H_5$ . **Methyl ether**  $C_9H_7Br(OMe)_2$ . (190°) at 20 mm. S.G. 1.396. From the dibromide, hot alcohol, and Zn (Wassermann, C. R. 88, 1206). **Di-bromide**  $C_9H_7Br_2(OMe)_2$ . **Dimethyl ether of di-bromo-di-ox-propyl-benzene**. (78°). From  $Br$  and a well-cooled solution of methyl-eugenol in ether. Silky needles.

**Ethyl ether**  $C_9H_7Br(OMe)(OEt)$ . [48°]. Prepared by the action of alcohol and Zn on its dibromide (Wassermann, A. 179, 385). **Di-bromide**  $C_9H_7Br_2(OMe)(OEt)$ . [80°]. From ethyl-eugenol and  $Br$ .

**Di-bromo-eugenol**  $C_9H_7Br_2(OMe)(OH)(C_6H_5)$ . [59°]. Glistening hexagonal prisms. V. sol. alcohol. Formed by boiling an alcoholic solution of the di-bromide with zinc-dust (Chasnowitz u. Hell, B. 18, 824).

**Di-bromide**  $C_9H_7Br_2(OMe)(OH)(C_6H_5)$ . [119°]. Glistening quadrate or trimetric tables. Sparingly soluble in ether and cold alcohol. Formed by bromination of eugenol.

#### BROMO-FLUORENE

$C_{12}H_8Br$  i.e.  $\langle C_{12}H_7 \rangle CH_2Br$ . [102°]. From fluorene,  $CHCl_3$ , and  $Br$  in the cold (Hodgkinson u. Matthews, C. J. 43, 165). Needles (from alcohol). V. sol.  $CHCl_3$ . Oxidises to bromo-di-phenylene ketone.

#### (a) Di-bromo-fluorene

$C_{12}H_6Br_2$  i.e.  $\langle C_{12}H_5 \rangle CH_2Br$ . **Di-bromo-di-phenylene-methane**. [165°] (Barbier, A. Ch. [5] 7, 479; Hodgkinson u. Matthews, C. J. 43, 164). Got by adding bromine to a solution of fluorene in  $CHCl_3$ . Monoclinic crystals,  $abc = 1.167:1.1065$ ;  $\beta = 77^\circ 52'$  (Arzruni, Z. Krist. 1, 624). Sol. boiling alcohol. Turned yellowish by light.  $CrO_3$  gives di-bromo-di-phenylene ketone.

**Sulphonic acid**  $C_{12}H_6Br.SO_3H$ . [142°]. Formed by sulphonation with  $ClSO_3H$  in  $CHCl_3$ .— $BaA'$ .

**( $\beta$ )-Di-bromo-fluorene**  $C_{12}H_6Br_2$ . [163°]. Formed together with the preceding (Fitting u. Schmitz, A. 193, 131). Monoclinic crystals;  $abc = 563:1:697$ .  $\beta = 78^\circ 21'$  (A.). Readily changes into two isomeric modifications ( $\gamma$ ) and ( $\delta$ ) (Lehmann, Z. Krist. 1, 626).

#### Tri-bromo-fluorene

$C_{12}H_4Br_3$  i.e.  $\langle C_{12}H_3 \rangle CHBr$ . [162°]. From fluorene (1 mol.) in  $CS_2$  and  $Br$  (3 mols.). Oxidised by  $CrO_3$  to ( $\beta$ )-di-bromo-diphenylene ketone (B.).

**DI-BROMO-FLUORESCIN**  $C_{20}H_{16}Br_2O_3$ . [260°-270°]. From fluorescein (1 mol.) and  $Br$  (2 mols.) in  $HOAc$  (Baeyer, A. 183, 1). Reddish-brown needles with green reflex. Dyes wool and silk salmon-pink.

**Di-acetyl derivative**  $C_{20}H_{14}Ac_2Br_2O_4$ . [210°].

#### Tetra-bromo-fluorescein

$C_{20}H_{12}Br_4O_3$  i.e.  $O \langle C_{12}H_9Br_2(OH) \rangle C \langle C_{12}H_9Br_2(OH) \rangle CO$ .

**Eosin**. Formed by adding  $Br$  to a solution of fluorescein in  $HOAc$ . It is purified by conversion into the K salt (Baeyer, A. 183, 36). Prepared by dissolving fluorescein (1 mol.) in

NaOHaq, adding a solution of Br (4 mols.) in NaOHaq, and acidifying. Orange needles (containing HOEt) (from alcohol), or flesh-coloured crystals  $C_{20}H_8Br_2O_5$  (from dilute alcohol containing HCl). Tetra-bromo-fluorescein is v. sl. sol. water and benzene; its alkaline solutions are pink and show strong yellow fluorescence, they dye wool and silk pink. Zinc-dust and NaOH reduce it to a leuco-compound, which is reoxidised by air. Potash-fusion forms di-bromo-resorcin and di-bromo-resorcin-phthalcin. Conc.  $H_2SO_4$  forms  $C_{20}H_8Br_2O_{10}$ .  $PCl_5$  forms  $C_{20}H_8Cl_2Br_2O_5$ . Sodium amalgam forms fluorescein. Warming with conc. KOH gives a deep blue solution. Leuco HCl pps. unstable

Salts. —  $K_2(C_{20}H_8Br_2O_5)$  5aq. S. 50. —  $K_2A''HOEt$ . —  $(NH_4)_2A''$ . —  $BaA''2aq$ . —  $CaA''2aq$ . —  $AgA''$ . —  $(HOPh)A''$ .

*Methyl ether*  $C_{20}H_9MeBr_2O_5$ . *Methyl erythrin*.

*Ethyl ether*  $C_{20}H_{11}EtBr_2O_5$ . *Erythrin*. *Spirit-soluble eosin*. From  $K_2A''$ ,  $K_2HSO_4$ , and alcohol at  $150^\circ$ . From fluorescein, boiling alcohol and Br. Red crystals (from alcohol). Formed, together with a colourless ethyl-eosin, by heating silver eosin with EtI and alcohol at  $100^\circ$ . —  $KC_{20}H_{11}EtBr_2O_5$  aq; dyes a more violet shade than eosin.

*Di-ethyl ether*  $C_{20}H_{13}Et_2Br_2O_5$ . From  $AgA''$  and EtI.

*Acetyl derivative*  $C_{20}H_8Ac_2Br_2O_5$  (?). [278°].

**BROMOFORM**  $CHBr_3$ . *Tri-bromo-methane*. Mol. w. 253. [8°]. (151°). S.G. 2.8341 (T.); 2.9045 (Perkin, *C. J.* 45, 533); 2.8842 (P.). C.E. (0° 10') .000944; (0° 100') .0010116. S.V. 103.53 (Thorpe, *C. J.* 37, 203). M.M. 11.626 at  $17.9^\circ$  (P.). V.D. 8.63 (calc. 8.75) (Cahours, *A. Ch.* [3] 19, 481).

*Occurrence*. — In crude bromine (Hermann, *A.* 95, 211; Dyson, *C. J.* 43, 36).

*Formation*. — 1. By the simultaneous action of Br and KOH, or by 'bromide of lime,' on alcohol or acetone, or by decomposing bromal with alkalis (Löwig, *A.* 3, 295; Dumas, *A. Ch.* [2] 56, 120; Günther, *Ar. Ph.* [3] 25, 373). — 2. From  $CH_2Cl_2$  and  $HBr$  (Holand, *A.* 240, 236).

*Reactions*. — 1. Alcoholic KOH forms CO (3 vols.) and ethylene (1 vol.) but no formate (Long, *Ar. Ph.* [3] 25). — 2. Br in presence of dilute KOH in sunlight forms  $CBr_4$  (Hermann, *B.* 6, 549). — 3. Reduced to  $CH_4$  by KI, water, and Zn or Cu (Berthelot, *A. Ch.* [3] 51, 48) or by the copper-zinc couple (Gladstone & Tribe, *C. J.* 28, 510).

**BROMO-FUMARIC ACID**  $C_4HBr(CO_2H)_2$ . [178°].

*Formation*. — 1. From iso-di-bromo-succinic acid by heating at  $180^\circ$  or by boiling with water (Kekulé, *A. Suppl.* 2, 91; A. 130, 1). — 2. From di-bromo-succinic acid and water at  $140^\circ$  (Bandrowski, *B.* 12, 315). — 3. By dissolving acetylene-di-carboxylic acid in strong aqueous  $HBr$  (Bandrowski, *B.* 15, 2697). — 4. From (88)-dibromopyromucic acid and from (8)-bromopyromucic acid by dilute  $HNO_3$  (Hill & Sanger, *A.* 232, 82, 64). — 5. From bromo-maleic acid and cold fuming  $HBr$  (Fittig & Petri, *A.* 196, 67).

*Properties*. — Lamine; v. s. sol. water, v. sol. alcohol and ether. At  $200^\circ$  it changes to bromo-maleic acid or its anhydride. Sodium-amalgam forms fumaric acid. Br gives the same tri-bromo-succinic acid as with bromo-maleic acid. Fuming  $HBr$  combines slowly in the cold; at  $100^\circ$  it quickly forms iso-di-bromo-succinic acid. With its equivalent of aniline it unites immediately to form the acid aniline salt. This does not give an anilide on standing for weeks in contact with cold water. On boiling its aqueous solution the same substance is obtained as on heating aniline bromo-maleate, viz.  $C_{16}H_{12}N_2O_2$ . [230°] (Michael, *Ann.* 9, 180).

Salts. —  $AgA''$ . —  $PbA''2aq$ . —  $A''H(NH_4Ph)$ : [154°] (Michael, *B.* 19, 1373).

*Dimethyl ether*  $A''Me_2$ . [30°] (Anschütz, *B.* 12, 2281).

**Di-bromo-fumaric acid**

$CO_2H.CBr.CBr.CO_2H$ . [220°]. Colourless crystals. Prepared by the addition of bromine to acetylenedicarboxylic acid. On distillation it is converted into dibromomaleic acid [108°].

Salts. —  $AgA''2aq$ . —  $PbA''$  (Bandrowski, *B.* 12, 2213).

( $\beta$ )-**BROMO-FURFURANEC**  $C_5H_4BrO$ . (103°). From the corresponding bromo-pyromucic acid by distilling with lime (Canzoneri & Oliveri, *G.* 17, 42). Heavy oil.

( $\alpha$ )-**Di-bromo-furfurane**  $C_5H_4Br_2O$  i.e.

$HC \begin{array}{l} \diagup CBr \\ \diagdown CBr \end{array} O$ . [10°]. (63°) at 15 mm.; (165°) at 761 mm. Formed by adding bromine to an alkaline solution of ( $\beta$ )-bromo-pyromucic acid [181°]. On oxidation it gives fumaric and maleic acids.

*Tetra-bromide*  $C_5H_2Br_4O$ : [111°]; by long boiling with water it yields bromo-fumaric and bromo-maleic acids (Hill & Hartshorn, *B.* 16, 1132; *B.* 18, 448; A. 232, 53).

( $\beta$ )-**Di-bromo-furfurane**  $\begin{array}{l} CBr:CH \\ | \\ CBr:CH \end{array} O$ . (166°).

Formed by distilling di-bromo-pyromucic acid (1 pt.) with  $Ca(OH)_2$  (2 pts.) (Canzoneri & Oliveri, *G.* 15, 116).

**Tetra-bromo-furfurane**  $C_5Br_4O$  [65°]. From ( $\beta$ )-di-bromo-pyromucic acid, or from tri-bromo-pyromucic acid, water and bromine vapour. Formed also by the action of alcoholic KOH on di-bromo-furfurane tetrabromide (Hill & Sanger, *A.* 232, 86, 96; *B.* 16, 1132; 17, 1760).

*Di-bromide*  $C_5Br_2O$ . [123°]. Six-sided plates. V. sol. ether, m. sol. alcohol and benzene. By boiling with water it yields di-bromo-maleic acid (Hill & Hartshorn, *B.* 18, 450).

**BROMO-FURIL** v. Furan.

**BROMO-GALLIC ACID** v. BROMO-TRI-OXY-BENZOIC ACID.

**TRI-BROMO-GUAIACOL**  $C_9H_7Br_3O_2$  i.e.  $C_9H_7Br_2(OMe)(OH)$ . [102°]. From guaiacol and Br (Tiemann & Koppe, *B.* 14, 2017).

**BROMO-GUANIDINE**  $CH_3BrN_3$ . From guanidine carbonate and Br (Kamenski, *B.* 11, 1600). Needles; detonates just above  $100^\circ$ .

**BROMO-GUANINE**  $C_5H_4N_4OBr$ . From guanine and bromine, crystallised from water. White powder. Sl. sol. boiling water, insol. cold water, alcohol or ether. — *B'HOL. Prisma.*

Converted by  $\text{NaNO}_2$  into bromo-xanthine (Fischer & Reese, A. 221, 841).

**TRI-BROMO-HEMIMELLITHOL** v. **Tribromo-tri-methyl-benzene** (1:2:3:4:5:6).

**BROMO-HEPTANE** v. **HEPTYL BROMIDE**.

**Di-bromo-heptane**  $\text{C}_7\text{H}_{14}\text{Br}_2$ . *Heptylene bromide*. S.G. 1.515. From heptane of paraffin oil. Decomposes at  $150^\circ$  (Thorpe & Young, A. 165, 121).

**Di-bromo-heptane**  $\text{C}_7\text{H}_{14}\text{Br}_2$  (211°). From heptane in the oil of *Pinus sabiniana* (Venable, A. C. J. 4, 22).

**Di-bromo-heptane**  $\text{CMe}_2\text{CMeBrCH}_2\text{Br}$ . From penta-methyl-ethyl alcohol and  $\text{PBr}_3$ . Easily fusible solid (Kaschirski, C. C. 1881, 278).

**Di-bromo-heptane**

$\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{Br}$ . *Heptylene bromide*. From canthanol and  $\text{PCl}_5\text{Br}_2$  (Braylants, B. 8, 409).

**Hexa-bromo-heptane**  $\text{C}_7\text{H}_4\text{Br}_6$ . From heptonene and Br. Oil (Saytzeff, A. 185, 144).

**$\alpha$ -BROMO-HEPTOIC ACID**  $\text{C}_7\text{H}_{13}\text{BrO}_2$  i.e.  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CHBrCO}_2\text{H}$  (250°). From Br and heptioic acid (Cahours, A. Suppl. 2, 83; Helms, B. 8, 1168; Hell & Schiele, B. 18, 625).

*Ethyl ether* EA' (c. 225°). S.G. 1.211.

**TETRA-BROMO-HEPTYL ALCOHOL**

$\text{C}_7\text{H}_7\text{Br}_4\text{O}$  i.e.  $(\text{CH}_2\text{Br})_4\text{CH}_2\text{CH}_2\text{OH}$ . From di-allyl-carbinol and Br (M. Saytzeff, A. 185, 135). Oil.

*Acetyl derivative*  $\text{C}_7\text{H}_{11}\text{BrOAc}$ . Converted by  $\text{AgOAc}$  into  $\text{C}_7\text{H}_{11}\text{O}_2(\text{OAc})_2$ , S.G. 1.180, whence baryta forms a syrup  $\text{C}_7\text{H}_{11}\text{O}(\text{OH})_2$  (Dieff, J. pr. [2] 35, 17).

**BROMO-HEPTYLENE**  $\text{C}_7\text{H}_{10}\text{Br}$  (158°). From the heptylene bromide of Venable.

**Bromo-heptylene**  $\text{C}_7\text{H}_{10}\text{Br}$  (165°). From the heptylene bromide of Braylants.

**BROMO-HEXADECANE** v. **HEXYL BROMIDE**.

**Di-bromo-hexadecane**  $\text{C}_{16}\text{H}_{32}\text{Br}_2$ . *Cetene bromide*. (134°). Colourless crystalline solid. Formed by addition of Br to cetene (Kraff, B. 17, 1373).

**BROMO-HEXANE** v. **HEXYL BROMIDE**.

**Di-bromo-hexane**  $\text{C}_6\text{H}_{12}\text{Br}_2$  i.e.

$\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{Br}$  (196°) at 710 mm. S.G. 1.5899. From the corresponding hexylene (Erlenmeyer & Wanklyn, J. 135, 111; cf. Hecht & Strauss, A. 172, 69; Hecht, B. 11, 1423).

**Di-bromo-hexane**  $\text{Me.CBr.CBr.Me.}$  (170°) (K); (140°) (E.). From  $\text{Me}_2\text{C.CMe.}$  and Br. Needles (from ether). Converted by heating with water and  $\text{PbO}$  at  $150^\circ$  into pinacol (Pawlow, A. 196, 121; Elieoff, J. R. 10, 229; Kaschirski, J. R. 13, 81).

**Di-bromo-hexane**  $\text{Me.CCHBr.CH.Br.}$  From  $\text{Me.C.CH}_2\text{CH}_2\text{.}$  Crystalline (Friedel & Silva, B. [2] 19, 289).

**Di-bromo-hexane**  $\text{C}_6\text{H}_{12}\text{Br}_2$  (211°). From hexane of petroleum (Prouze & Cahours, A. 121, 293).

**Tetra-bromo-hexane**  $\text{C}_6\text{H}_8\text{Br}_4$ . *Diallyl-tetrabromide*. (63°). From diallyl and Br (Wagner & Tolens, B. 6, 588).

**Tetra-bromo-hexane**  $\text{C}_6\text{H}_8\text{Br}_4$  (142°). From iodo-hexylene and Br (Bouchardat, Z. 1871, 699).

**Tetra-bromo-hexane**  $\text{C}_6\text{H}_8\text{Br}_4$ . From hexinene derived from mannite (Hecht, B. 11, 1064).

**Tetra-bromo-hexane**  $\text{C}_6\text{H}_8\text{Br}_4$ . From hexinene from di-methyl-allyl-carbinyl chloride (Saytzeff, B. 11, 2152).

**Tetra-bromo-hexane**  $\text{C}_6\text{H}_8\text{Br}_4$  (112°). (318° cor.). From hexinene derived from coal-tar (Sehorlemmer, A. 139, 250).

**Hexa-bromo-hexane**  $\text{C}_6\text{H}_4\text{Br}_6$ . From diallylene (Henry, B. 1, 199).

**Hexa-bromo-hexane**  $\text{C}_6\text{H}_4\text{Br}_6$  (77°). From di-bromo-diallyl (Henry, B. 7, 23).

**Hexa-bromo-hexane**  $\text{C}_6\text{H}_4\text{Br}_6$  (152°). From sec-hexyl iodide and Br at  $130^\circ$  (Merz & Weith, B. 11, 2250).

**Hexa-bromo-hexane**  $\text{C}_6\text{H}_4\text{Br}_6$ . From hexane and Br at  $125^\circ$  (Wahl, B. 10, 1251).

**Octo-bromo-hexane**  $\text{C}_6\text{H}_4\text{Br}_8$ . From hexane and Br (W.).

**Octo-bromo-hexane**  $\text{C}_6\text{H}_4\text{Br}_8$ . From sec-hexyl iodide and Br at  $130^\circ$  (M. & W.).

**Octo-bromo-hexane**  $\text{C}_6\text{H}_4\text{Br}_8$ . *Dipropargyl octobromide* (111°) (Henry, B. 7, 21).

**BROMO-HEXENOIC ACID**  $\text{C}_6\text{H}_9\text{BrO}_2$ . *Di-bromo-hydro-sorbic acid*. (95°). From sorbic acid and Br. Laminae (Fittig & Kachel, A. 168, 287).

**DI-BROMO-HEXINENE**  $\text{C}_6\text{H}_8\text{Br}_2$ . *Di-bromo-diallyl*. (210°). S.G. 1.456. From diallyl-tetrabromide and solid KOH (Henry, J. pr. [2] 8, 57).

**Tetra-bromo-hexinene**  $\text{C}_6\text{H}_4\text{Br}_4$ . *Propargyl tetrabromide*. S.G. 2.464. Liquid (Henry, B. 6, 959).

**$\alpha$ -BROMO-*n*-HEXOIC ACID**

$\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CHBrCO}_2\text{H}$ . *Bromo-caproic acid*. (210°). From caproic acid and Br (Cahours, A. Suppl. 2, 78).

*Ethyl ether* EA' (205°–210°) (Hell, B. 17, 2218).

**$\gamma$ -Bromo-*n*-hexoic acid**

$\text{CH}_3\text{CH}_2\text{CHBrCH}_2\text{CH}_2\text{CO}_2\text{H}$ . From hydro-sorbic, or iso-hydro-sorbic, acid and HBr. Oil. Sodium-amalgam reduces it to *n*-hexoic acid. Boiling water converts it into hydro-sorbic and oxy-hexoic acids (Fittig, A. 200, 42; Hjelt, B. 15, 618).

**$\gamma$ -Bromo-iso-hexoic acid**

$\text{Me.CBr.CH}_2\text{CH}_2\text{CO}_2\text{H}$ .

*Ethyl ether* AEI. Formed by saturating an absolute alcoholic solution of isocapro-lactone with HBr. By distillation it is decomposed into the original lactone and EtBr (Bredt, B. 19, 514).

**Bromo-hexoic acid**  $\text{C}_6\text{H}_{11}\text{BrO}_2$  (186°). From iso-pyroterebic acid and HBr; Prisma. AgA' (Lagermark & Elieoff, J. R. 11, 270).

**Bromo-hexoic acid**  $\text{C}_6\text{H}_{11}\text{BrO}_2$  (25°). From ethyl-crotonic acid and cone. HBrAq. Sodium-amalgam forms hydro-ethyl-crotonic acid. Aqueous  $\text{Na}_2\text{CO}_3$  even at 0° forms anylene, NaBr, and  $\text{CO}_2$ .

**$\alpha\beta$ -Di-bromo-iso-hexoic acid**

$\text{Pr.CHBr.CHBr.CO}_2\text{H}$  (39°). From pyroterebic acid and Br (W. & Williams, B. 6, 1095; Geisler, A. 208, 46). Large crystals (from CS<sub>2</sub>).

**Di-bromo-hexoic acid**  $\text{C}_6\text{H}_{10}\text{Br}_2\text{O}_2$  (68°). From sorbic acid and fuming HBr. Boiling water or alkalis produce sorbic acid, and other bodies (cf. Hjelt, B. 15, 620).

**Di-bromo-hexoic acid**  $\text{C}_6\text{H}_{10}\text{Br}_2\text{O}_2$ . From hydro-sorbic acid and Br in CS<sub>2</sub>. Liquid; decomposed by boiling water, giving oxy-hydro-sorbic acid (Fittig, A. 161, 314; 200, 46; Hjelt, B. 15, 619).

**Di-bromo-hexole acid**  $C_6H_8Br_2O_2$ . From isosorbic acid and HBr. Oil (L. a. E.).

**Di-bromo-hexoic acid**  $CH_2Br.CMe.Br.CO_2H$ . [98°]. From methyl-ethyl-acrylic acid and Br. Monoclinic crystals,  $a:b:c = 96:11:53$ ,  $\beta = 94^\circ 36'$ . Water at 100° forms bromo-amylene  $CH_2Br.CMe.Br$ , methyl-ethyl-acrylic acid, di-oxy-hexoic acid, and methyl ethyl ketone (Lieben, a. Zeisel, M. 4, 78).

**Di-bromo-hexoic acid**  $C_6H_8Br_2O_2$ . [81°]. From ethyl-crotonic acid and Br. Decomposed by cold  $Na_2CO_3$  aq into bromo-amylene, NaBr, and  $CO_2$  (Pittig, A. 200, 35).

**Tetra-bromo-hexoic acid**  $C_6H_4Br_4O_2$ . [183°]. From sorbic acid and Br (Pittig, A. 161, 323; 168, 277; 200, 58). Monoclinic crystals (from alcohol). More stable than the preceding acids, not being attacked by water at 100°. —  $NaA'$  2aq. —  $CaA'$  7aq. —  $BaA'$  11aq.

**DI-BROMO-HEXOIC ALDEHYDE**  $C_6H_8Br_2O$  i.e.  $CH_2Br.CHBr.CMe.Br.CO$ . *Di-bromo-methyl-propyl-acetic aldehyde*. From Br and cold methyl-ethyl-acrolein. Pungent oil. —  $(C_6H_8Br_2O)NaHSO_3$  3aq (Lieben a. Zeisel, M. 4, 19).

**BROMO-HEXONENE**  $C_6H_8Br$ . *Bromo di-allylene*. (150°). From di-bromo di-allyl and KOH. Pps. ammoniacal  $AgNO_3$  and cuprous chloride (Henry, B. 14, 400).

**Octo-bromo-hexonene**  $C_8Br_8$ . From *sec*-hexyl iodide and Br at 140°. Prisms. At 200° it splits up into Br and hexa-bromo-benzene (Merz a. Weith, B. 11, 2247).

**BROMO-HEXYL ALCOHOL**  $C_6H_{13}BrO$  i.e.  $CH_3CHBr.CH(OH).CH_2Et$ . (189°). S.G. 1.3. Liquid. From hexylene oxide and Br (Henry, C. R. 97, 260; B. 12, 41, 363).

**Di-bromo-hexyl alcohols v. Dibromides of HEXENYL ALCOHOLS.**

**DI BROMO-HEXYL-BENZENE**  $C_8H_{10}Br_2$  i.e.  $Ph.CHBr.CHBr.CH_2(CH_2)_3$ . [80°]. From hexyl-benzene (*q. v.*). Needles or plates.

**BROMO-HEXYLENE**  $C_6H_8Br$ . (138° 11') at 739 mm. S.G. 1.2025. From (*β*)-hexylene bromide and alcoholic KOH (Caventou, A. 135, 126; Reboil a. Truchot, A. 144, 247; Hecht, B. 11, 1424; A. 172, 70). See also HEXENYL BROMIDE.

**Di-bromo-hexylene**  $C_6H_8Br_2$ . S.G. 1.698. From hexylene (derived from mannite) and Br (Henry, B. 11, 1054).

**Tetra-bromo-hexylene**  $C_6H_4Br_4$ . From di-allylene and Br (Henry, C. R. 87, 174).

**Octo-bromo-hexylene**  $C_8H_8Br_8$ . [181°]. From *sec*-hexyl iodide and Br at 130° (Merz a. Weith, B. 11, 2249; Hecht, B. 11, 1420).

**Octo-bromo-hexylene**  $C_8H_8Br_8$ . From hexane and Br at 125° (Wahl, B. 10, 402).

**BROMO-HIPPURIC ACID**  $C_8H_7BrNO_2$  i.e.  $C_6H_4Br.CO.NH.CO_2H$ . From hippuric acid, alcohol, and Br. Slender needles. Possibly identical with the following acid. —  $CaA'_2$  (Mayer, Z. 1865, 415).

**p-Bromo-hippuric acid**

[1.4]  $C_6H_4Br.CO.NH.CO_2H$ . Excreted when *p*-bromo-toluene is taken with food. Flat needles (from water). Boiling HClAq forms glycocholl and *p*-oxy-benzoic acid (Preusse, H. 5, 63).

**BROMO-HYDRATROPIC ACID v. Bromo-PHENYL-PROPIONIC ACID.**

**BROMHYDRIN v. GLYCIDIN.**

**Tri-bromhydrin v. TRI-BROMO-PROPANE.**

**p-BROMO-HYDROCARBOSTYRIL**  $C_8H_7BrNO$

i.e.  $C_6H_5(Br) \begin{matrix} C_6H_5CO \\ \backslash \\ NH \end{matrix} [4\frac{1}{2}]. [178^\circ].$  Long

flat needles. V. sol. alcohol, ether, benzene and acetic acid. Prepared by reduction of *p*-bromo-*o*-nitro-hydro-cinnamic acid with tin and HCl (Gabriel a. Zimmermann, B. 13, 1683).

**BROMO-HYDROCINNAMIC ACID v. Bromo-PHENYL-PROPIONIC ACID.**

**DI-BROMO-HYDRO-CERULIGNON v. CERULIGNON.**

**BROMO-HYDROQUINONE**  $C_6H_4Br_2$  i.e.  $C_6H_4Br(OH)_2$ . [111°].

**Formation.** — 1. Together with di-bromo-hydroquinone, by the action of conc. HBrAq on quinone (Wichellians, B. 12, 1504). — 2. From hydroquinone (1 mol.) and Br (1 mol.) in ether-chloroform (Sarauw, A. 209, 99).

**Properties.** — Leaflets; may be sublimed. V. e. sol. water, alcohol, and benzene.  $Fe_2Cl_6$  forms bromoquinone.

**Di-acetyl derivative**  $C_8H_8Br_2(OAc)_2$ . [73°]. Formed, together with di-acetyl di-bromo-hydroquinone by heating quinone with AcBr (Schulz, B. 15, 655). Needles, sol. alcohol and benzene.

**Di-bromo-hydroquinone**  $C_6H_4Br_2(OH)_2$ . [187°].

**Formation.** — 1. As above (W.). — 2. From hydroquinone and Br in HOAc (Benedikt, M. 1, 345). — 3. From quinone and Br (Sarauw).

**Properties.** — Long needles (from water). Converted by  $Fe_2Cl_6$  or bromine-water into di-bromoquinone.

**Di-acetyl derivative**  $C_8H_8Br_2(OAc)_2$ . [161°]. Formed as above (Schulz). Needles, sol. chloroform and ether.

**Methyl ether**  $C_6H_4Br_2(OH)(OMe)$ . From methyl-hydroquinone and Br (B.).

**Di-methyl ether**  $C_6H_4Br_2(OMe)_2$ . [142°]. From di-methyl-hydroquinone and Br in HOAc (Habermann, B. 11, 1036). Methyl-ethyl ether  $C_6H_4Br_2(OMe)(OEt)$ . [88°]. Prepared like the preceding (Fiala, M. 6, 913).

**Di-isobutyl ether**  $C_6H_4Br_2(OC_4H_9)_2$ . From  $C_6H_4(OC_4H_9)_2$  and Br (Schulert, M. 3, 684). Plates (from HOAc).

**Di-bromo-hydroquinone**  $C_6H_4Br_2(OH)(OBr)$  (?). *Bromoxy-bromo-phenol*. [87°]. From quinone (1 mol.) and Br (1 mol.) in chloroform (Sarauw). Golden tables, sl. sol. ether and  $CHCl_3$ , decomposed by water into HBr and bromoquinone; changes slowly to  $C_6H_4Br_2(OH)_2$ .

**Tri-bromo-hydroquinone**  $C_6H_3Br_3(OH)_2$ . [136°]. Formed together with tetra-bromo-hydroquinone, by treating di-bromo-quinone with conc. HBr, or by the action of Br (6 mols.) on hydroquinone (2 mols.) or quinone (3 mols.) (Sarauw, A. 209, 116). Silky needles, sol. alcohol and benzene, v. sol. boiling water.  $Fe_2Cl_6$  gives tri-bromo-quinone.

**Tetra-bromo-hydroquinone**  $C_6Br_4(OH)_2$ . [244°]. Prepared as above (Sarauw). Prepared also by reducing tetra-bromo-quinone (brom-anil) with  $SO_2$  or HI and P (Stenhouse, A. 91, 310; Suppl. 8, 20) or by warming it with conc. HBrAq. Slender needles (from HOAc); insol. boiling water, v. sol. alcohol.  $Fe_2Cl_6$  forms tetra-bromo-quinone.

**BROMO-HYDROQUINONE-PHTHALEIN** v. **HYDROQUINONE-PHTHALEIN**.**DI-BROMO-HYDROSEBIC ACID** v. **BROMO-HEXENOIC ACID**.**BROMO-HYDRO-THYMOQUINONE**

$C_{10}H_8BrO_2$ , i.e.  $C_6H_4(C_2H_4)(CH_3)Br(OH)_2$ . [58°]. From thymoquinone and HBr (Schniter, *B.* 20, 1318). Oxidises to bromothymoquinone [45°]. The di-acetyl derivative is formed by the action of acetyl-bromide on thymoquinone.

*Di-acetyl derivative* [91°]. Rhombohedral crystals (Schulz, *B.* 15, 657).

**Di-bromo-hydro-thymoquinone**

$C_6(C_2H_4)(CH_3)Br(OH)_2$ .

*Di-acetyl derivative* [122°]. Colourless tables (Schulz, *B.* 15, 658).

**BROMO-HYDRO-TOLUQUINONE**

$C_9H_7Br(OH)_2$ . [c. 160°]. Formed by the action of cold conc. HBr upon toluquinone. (Glistening plates (Schniter, *B.* 20, 2286).

**Tri-bromo-hydro-toluquinone**

$C_9H_5Br_3O_2$ , i.e.  $C_6H_3Br_3Me(OH)_2$ . [202°]. From tri-bromo-toluquinone and  $SO_2$ . Needles, sol. water (Canzoneri a. Spica, *G.* 12, 471).

**BROMO-HYPOGÆIC ACID** v. **HYPOGÆIC ACID**.

**DI-BROMO-ICOSYLENE**  $C_{20}H_{38}Br_2$ . Oil. From icosinene and Br (Lippmann a. Hawliczek, *B.* 12, 69).

**DI-BROMO-INDIGO**  $C_{16}H_8Br_2N_2O$ , i.e.

$C_8H_7Br \begin{smallmatrix} O \\ \diagup \diagdown \\ C \\ \diagdown \diagup \\ N \end{smallmatrix} C = C \begin{smallmatrix} O \\ \diagup \diagdown \\ C \\ \diagdown \diagup \\ N \end{smallmatrix} C_8H_7Br$ . Formed by

boiling  $\omega$ -di-bromo-*m*-bromo-*o*-amido-acetophenone [5:2:1]  $C_8H_7Br(NH_2)CO.CHBr_2$  or  $\omega$ -dichloro-*m*-bromo-*o*-amido-acetophenone [5:2:1]  $C_8H_7Br(NH_2)CO.CHCl_2$  or their acetyl derivatives with dilute NaOH and exposure to the air (Baeyer a. Bloem, *B.* 17, 968). Prepared by heating bromo-isatin with  $PCl_5$  and treating the product with a 10 p.c. solution of HI in acetic acid and then with aqueous  $SO_2$ . Some isomeric di-bromo-indipurpurin is formed at the same time (Baeyer, *B.* 12, 1315). Small black needles, may be sublimed; v. sl. sol. most menstrua. May be reduced to a 'vat' like indigo.

**BROMO-INDIRUBIN**  $C_{16}H_8BrN_2O_2$ . Long needles. Formed by the action of  $Na_2CO_3$  on an alcoholic solution containing in-oxy and bromo-isatin (Baeyer, *B.* 14, 1745).

 **$\beta$ -BROMO-IODO-ACRYLIC ACID**

$C_3H_3BrO_2$ , i.e.  $CHBr.CH.CO_2H$ . [110°]. S. 1-7 at 20°. From bromo-propionic acid and HI (Hill, *Am.* 3, 175). Scales. —  $BaA'$ , 3aq. S. (of  $BaA'$ ) 16 at 20°. —  $CaA'$ , 3!aq. —  $AgA'$ .

$\alpha\beta$ -Bromo-iodo-acrylic acid  $CHBr.CHBr.CO_2H$ . [96°]. Formed by the addition of HBr to  $\beta$ -iodo-propionic acid (Homolka a. Stolz, *B.* 18, 2284). Needles; sl. sol. cold water. By heating in alcoholic solution with AgBr it yields  $\alpha\beta$ -di-bromo-acrylic acid [85°] (Stolz, *B.* 19, 537).

$\beta\alpha$ -Bromo-iodo-acrylic acid  $CHBr.Cl.CO_2H$ . [71°]. Colourless crystals. V. sol. water. Formed by boiling propionic acid with an ethereal solution of BrI (Stolz, *B.* 19, 536).

 **$\beta\beta$ -Bromo-di-iodo-acrylic acid**

$CHBr.Cl.CO_2H$ . [160°]. S. 2 at 20°. From bromo-propionic acid and iodine in ether. Flat six-sided plates. —  $BaA'$ , 4aq. S. 16-26 at 20°. —

$CaA'$ , —  $KA'$ . —  $AgA'$  (Mabery a. Lloyd, *Am.* 2, 124).

 **$\alpha\beta\beta$ -Bromo-di-iodo-acrylic acid**

$Cl_2.CBr.CO_2H$ . [182°]. Glistening colourless plates. Formed by the action of iodine bromide upon iodo-propionic acid in ethereal solution (Homolka a. Stolz, *B.* 18, 2286).

 **$\beta\beta\alpha$ -Di-bromo-iodo-acrylic acid**

$CHBr.Cl.CO_2H$ . [140°]. S. 3-5 at 20°. From bromo-propionic acid and IBr (Mabery a. Lloyd, *Am.* 4, 94; *N. Am.* 4, 17, 94). Monoclinic prisms (from water); *act.*  $\alpha$  617:1:581. —  $BaA'$ , 3!aq. S. 16-7 at 20°.  $CaA'$ , —  $AgA'$ .

 **$\delta\alpha\beta$ -Di-bromo-iodo-acrylic acid**

$CHBr.CBr.CO_2H$ . [147°]. Long silky needles. Sl. sol. cold water. Formed by the action of a solution of bromine in chloroform upon iodo-propionic acid  $ICl.CCO_2H$  (Homolka a. Stolz, *B.* 18, 2285).

**DI-BROMO-IODO-ALLYL ALCOHOL**.

*Ethyl ether*  $C_3H_5Br_2IO$ , i.e.

$CHBr.CBr.CH_2.OEt$ . Oil. From iodo-propargyl ethyl ether and Br (Lieberrmann, *A.* 135, 286).

***o*-BROMO-IODO-BENZENE**  $C_6H_4BrI$  [1:2]. (257°). From *o*-bromo-aniline or *o*-iodo aniline by the diazo reaction (Körner, *G.* 4, 339).

***m*-Bromo-iodo benzene**  $C_6H_4BrI$  [1:3]. (252°). Similarly prepared (K.).

***p*-Bromo-iodo-benzene**  $C_6H_4BrI$  [1:4]. [92°]. (252°). Similarly prepared (Griess, *J.* 1866, 452; K.).

*Dichloride*  $C_6H_4BrI.Cl_2$ . [115°-120°, with decomposition]. Ppd. as yellow needles when chlorine is passed into a solution of bromo-iodo-benzene in chloroform (C. Willgerodt, *J. pr.* [2] 33, 158). With alcohol it forms aldehyde and  $C_6H_5BrI$ . It converts metallic and alcoholic iodides into chlorides, iodine being separated.

**Tri-bromo-iodo-benzene**  $C_6H_3Br_3I$  [1:3:5:6]. [101°]. Obtained by adding conc. HI to a solution of  $C_6H_4Br_2.N.N.NO_2$ . Colourless needles, sol. hot alcohol (Silberstein, *J. pr.* [2] 27, 120).

**Tri-bromo-iodo-benzene**  $C_6H_3Br_3I$  [1:2:4:5]. [165°].

*Dichloride*  $C_6H_3Br_2Cl_2$ . Formed by dissolving  $C_6H_3Br_3$  in  $CHCl_3$  and passing in  $Cl_2$  (Willgerodt, *J. pr.* [2] 33, 159).

***s*-BROMO-IODO-ETHANE**  $C_2H_4BrI$ , i.e.

$CH_2Br.CH_2I$ . *Ethylene bromiodide*. [23°]. (163°) S.G. 2 2-516. From bromo-ethylene and conc.  $HIAg$  at 100° (Reboul, *A.* 155, 224; also from ethylene and BrI (Maxwell Simpson, *Pr.* 22, 51). Needles; sl. sol. cold alcohol. Alcoholic KOH gives iodo-ethylene and acetylene (Lagermark, *J. R.* 5, 334).

***u*-Bromo-iodo-ethane**  $CH_3.CHBrI$ . *Ethyl-iodine bromiodide*. (142°). S.G. 1 2-452. From bromo-ethylene and conc.  $HIAg$  at 4° (R.), or from *u*-di-iodo-ethane and IBr (Maxwell Simpson, *Pr.* 27, 424). Alcoholic KOH forms bromo-ethylene.

**Di-bromo-iodo-ethane**  $C_2H_4Br_2$ . (170°-180°). S.G. 2 2-86. From bromo-ethylene and IBr (M. Simpson, *Pr.* 22, 51).  $Ag_2O$  forms  $C_2H_3Br$ .

***s*-BROMO-IODO-ETHYLENE**  $C_2H_2BrI$ . *Acetylene bromiodide*. [c. 8°]. (150° cor.). S.G. (solid) 2 2-750; 172-2-627. Got by passing acetylene into aqueous solution of BrI, the product being treated with  $Na_2S_2O_3$  and distilled with steam (Plimpton, *C. J.* 41, 896; Sabanejeff, *A.*

216, 266). With alcoholic NaOH it appears to give off  $C_2HBr$ .

***u*-Bromo-iodo-ethylene**  $CH_2:CBrl$ . (129°). S.G.  $\frac{2}{3}$  2.565. From chloro-bromo-iodo-ethane and alcoholic KOH (Henry, *C. R.* 98, 741). Slowly absorbs oxygen from air.

**Di-bromo-iodo-ethylene**  $CHBr:CHBr$ . [66°]. Small prisms. Formed by the action of an aqueous solution of bromine upon iodo-propionic acid  $ICl:C.CO_2H$ ,  $CO_2$  being evolved (Homolka & Stolz, *B.* 18, 2285).

**BROMO-IODO-METHANE**  $CH_3BrI$ . *Methyl-ene bromide*. (139). S.G.  $\frac{16.8}{100}$  2.926. V.D. 9.65. From methylene iodide and Br or IBr (Henry, *C. R.* 101, 299).

**Di-bromo-iodo-methane**  $CHBr_2I$ . *Bromiodoform*. [6]. From iodoform and Br (Scrullas, *A. Ch.* [2] 31, 225; 39, 97; Bouchardat, *J. Ph.* 23, 10).

**BROMO-IODO-NAPHTHALENES**  $C_{10}H_8BrI$ . The three following are obtained from the corresponding bromo-naphthylamines by the diazo-reaction (Meldola, *C. J.* 47, 523):

( $\alpha$ )-**Bromo-iodo-naphthalene**  $C_{10}H_7BrI$  [1.4]. [84]. Large flat needles; insol. water; sol. alcohol and glacial HOAc, v. c. sol. benzene and ether.

( $\beta$ )-**Bromo-iodo-naphthalene**  $C_{10}H_7BrI$  [1.3]. [68°]. Needles.

( $\gamma$ )-**Bromo-iodo-naphthalene**  $C_{10}H_7BrI$  [1.2]. [94°]. Thick needles.

#### BROMO IODO-NITRO-BENZENE

***C*<sub>6</sub>H<sub>4</sub>Br(NO<sub>2</sub>)** [1.2.5]. [106°]. From  $C_6H_5Br$  [1.2] and  $HNO_3$  or from  $C_6H_4Br(NH_2)(NO_2)$  [1.2.5] (Körner, *U.* 4, 383). Needles or prisms. Alcoholic  $NH_3$  displaces I by  $NH_2$ .

**Bromo-iodo-nitro-benzene**  $C_6H_4BrI(NO_2)$  [1.3.3]. [90]. From  $C_6H_4Br(NH_2)(NO_2)$  [1.3.3] (K.).

**Bromo-iodo-nitro-benzene**  $C_6H_4BrI(NO_2)$  [1.3.4]. [84°]. From  $C_6H_4Br(NH_2)(NO_2)$  [1.3.4] (K.). Alcoholic  $NH_3$  displaces I by  $NH_2$ .

**Bromo-iodo-nitro-benzene**  $C_6H_4BrI(NO_2)$  [1.3.6]. [127°]. Formed, together with the following body, by dissolving *m*-bromo-iodo-benzene in fuming  $HNO_3$  (K.). Alcoholic  $NH_3$  displaces Br by  $NH_2$ .

**Bromo-iodo-nitro-benzene**  $C_6H_4BrI(NO_2)$  [1.3.2]. Needles.

#### BROMO-IODO-NITRO-PHENOL

***C*<sub>6</sub>H<sub>3</sub>(OH)(NO<sub>2</sub>)BrI** [1.2.4.6]. [101°]. From (1,3,4)-bromo-nitro-phenol, KOH,  $HIO_3$ , and I (Körner, *Z.* 1867, 617). Monoclinic tables  $a:b:c = 5.20:1.1:0.87$ ;  $\beta = 65^\circ 32'$  (Groth, *Z. Kryst.* 1, 437); volatile with steam. — KA' — NaA'.

**Bromo-iodo-nitro-phenol**  $C_6H_3(OH)(NO_2)BrI$  [1.2.6]. From (1,3,6)-bromo-nitro-phenol as above (K.). Prisms (from ether). — KA': yellow needles.

#### BROMO IODO-NITRO-TOLUENE

***C*<sub>6</sub>H<sub>3</sub>MeBrI(NO<sub>2</sub>)** [1.3.4.2]. [118°]. Formed by nitrating (1,3,6)-bromo-iodo-toluene. Needles (Wroblewsky, *A.* 168, 160).

**Bromo-iodo-nitro-toluene**  $C_6H_3MeBrI(NO_2)$  [1.3.2 or 6.2]. From the corresponding bromo-iodo-toluene (W.).

**Di-bromo-iodo-nitro-toluene**  $C_6H_2MeBr_2I(NO_2)$  [1.3.5.4.2]. [69°]. From  $C_6H_3MeBrI(NO_2)$  by nitration (Wroblewsky, *A.* 192, 210). Large needles. Volatile with steam.

**Di-bromo-di-iodo-nitro-toluene**  $C_6H_2MeBr_2I_2(NO_2)$  [1.3.5.4.2.6]. [129°]. From

$C_6H_2MeBr_2I$ , and fuming  $HNO_3$ . Yields on reduction by Sn and HCl an amido-compound which is converted by further treatment by Sn and HCl to *o*-toluidine (W.).

#### BROMO-DI-iodo-PHLOROGLUCIN

***C*<sub>6</sub>(OH)<sub>3</sub>Br<sub>2</sub>I**. From tri-bromo-phloroglucin and aqueous KI. Decomposed by heat (Benedikt & Schmidt, *M.* 4, 605).

#### BROMO-IODO-PROPANE

***C*<sub>3</sub>H<sub>7</sub>BrI** *i.e.*  $CH_3.CBrI.CH_3$ . (148°). S.G.  $\frac{14}{100}$  2.20. Formed by union of HI with allylic hydrobromide (Heboul, *C. R.* 74, 669, 944).

**Bromo-iodo-propane**  $CH_3.CHI.CH_2Br$  or  $CH_3.CHI.Br.CH_2I$ . (160°–168°). From propylene, water, and IBr (M. Simpson, *Pr.* 22, 51).

**DI-BROMO-IODO-PROPYLENE**  $C_3H_4Br_2I$  (?). From iodo-allylene and Br. Does not combine with Br (Liebermann, *A.* 135, 275).

#### DI-BROMO-IODO-STEARIC ACID

***C*<sub>18</sub>H<sub>33</sub>Br<sub>2</sub>IO<sub>2</sub>**. From ricinoleic acid  $C_{18}H_{33}O_2$ , *vid*  $C_{18}H_{33}IO_2$  (Claus, *B.* 9, 1917).

#### BROMO IODO-TOLUENE

***C*<sub>6</sub>H<sub>4</sub>MeBrI** [1.2.3 or 5]. (260°). S.G.  $\frac{12}{100}$  2.139. From  $C_6H_5MeBr$  (NH<sub>2</sub>) (Wroblewsky, *A.* 168, 164).

**Bromo-iodo-toluene**  $C_6H_4MeBrI$  [1.3.4]. (265°). S.G.  $\frac{20}{100}$  2.014. From the corresponding bromo-toluidine (W.).

**Di-bromo-iodo-toluene**  $C_6H_3MeBr_2I$  [1.3.5.4]. [86°]. (270°). From  $C_6H_4MeBr(NO_2)(NH_2)$  *vid*  $C_6H_4MeBr(NO_2)I$ , and  $C_6H_4MeBr(NH_2)I$  (Wroblewsky, *A.* 192, 209). Also from di-bromo-*p*-toluidine,  $C_6H_4MeBr_2(NH_2)$  by diazo-reaction.

**Di-bromo-di-iodo-toluene**  $C_6H_3MeBr_2I_2$  [1.3.5.4.2]. [68°]. From  $C_6H_4MeBrI(NH_2)$  by diazo-reaction (Wroblewsky, *A.* 192, 212).

#### DI-BROMO-IODO-TOLUIDINE

***C*<sub>6</sub>H<sub>3</sub>MeBr<sub>2</sub>I(NH<sub>2</sub>)** [1.3.5.4.2]. [64°]. By reduction of the corresponding nitro-compound (Wroblewsky, *A.* 192, 210). Converted by sodium amalgam into *o*-toluidine.

• **Acetyl derivative**  $C_6H_3MeBr_2I(NHAc)$

[121°]. Small white needles.

#### BROMO-ISATIC ACID v. ISATIC ACID.

#### BROMO-ISATIN v. ISATIN.

#### BROMO-ISATOIC ACID v. ISATOIC ACID.

#### BROMO-ISO- v. BROMO-

#### BROMO-ITACONIC ACID

***C*<sub>6</sub>H<sub>4</sub>BrO<sub>4</sub>**. [164°]. Formed by the dry distillation of *ita*-di-bromopyrotartaric acid (Swarts, *J.* 1873, 584). Its anhydride is formed similarly from *ita*-di-bromopyrotartaric anhydride (Petri, *B.* 14, 1637). Alkalis form itaconic acid; Sn reduces it to itaconic acid.

• **BROMO-LACTIC ACID v. BROMO-OXY-PROPIONIC ACID.**

**DI-BROMO-LAURENE**  $C_{18}H_{33}Br_2$  (?) [210°]. From laurene and Br (Montgolfier, *A. Ch.* [5] 14, 93).

**Tri-bromo-laurene**  $C_{18}H_{33}Br_3$  (?) [125°]. From laurene and Br in the cold (Fittig, Köbrich & Jilke, *A.* 145, 449). *Cf.* LAURENE.

• **BROMO-LEVULIC ACID v. BROMO-ACETYL-PROPIONIC ACID.**

• **BROMO-LUTIDINE v. BROMO-DI-METHYL-PYRIDINE.**

**BROMO-MALEIC ACID**  $C_4H_2Br(CO_2H)_2$ , *i.e.*  $CO_2H.CH(CBr).CO_2H$ , or  $CO_2H.C(CBr).CO_2H$ ,  $CH_2C(OH)(CBr).CO_2H$ , or  $\parallel$   $CH \cdot CO \begin{matrix} \diagup O \\ \diagdown CBr \end{matrix}$ , or  $\parallel$   $CH \cdot CO \begin{matrix} \diagup O \\ \diagdown CBr \end{matrix}$ . [128°].

Formed by boiling di-bromo-succinic acid or its Na salt with water (Kekulé, *A. Suppl.* 1, 307; Petri, *A.* 195, 62). Formed also, together with bromo-fumaric acid (*q. v.*) by the action of Br and water on succinic acid at 180° (Kekulé, *A.* 130, 1), or fumaric acid at 100° (Carius, *J.* 149, 264). Deliquescent prisms or needles; *v. c.* sol. water, alcohol, and ether, splits up into water and its anhydride on distillation.

For discussion of formula see MALIC ACID.

**Reactions.**—1. *Sodium amalgam* gives succinic acid. 2. Fuming HBr unites in the cold, forming di-bromo-succinic acid. 3. *Electrolysis* of its Na salt gives CO and HBr. 4. Boiling conc. *bartha-water* forms oxalic and acetic acids.—5. When it is dissolved in water and an equivalent of aniline is added the mixture separates a crystalline pp.  $C_6H_5Br \cdot CO \cdot H \cdot CO \cdot H \cdot NH_2 \cdot C_6H_5$ . [128°]. This acid anilide salt dissolved in water and allowed to stand deposits the acid anilide  $CO \cdot H \cdot C \cdot HBr \cdot CO \cdot NH_2 \cdot C_6H_5$ , which crystallizes in prisms; insol. in dilute HCl. If instead of allowing the substance to react in the cold the solution is heated, the compounds  $C_6H_5H_2N_2O_2$  and  $C_6H_5H_2N_2O_4$  are obtained.

$C_6H_5H_2N_2O_2$ , probably  $\begin{matrix} C(NHPh) \cdot CO \\ | \\ CH_2 \end{matrix} \cdot NHPh$ , [230°], forms ochre-colored microscopic needles. Insol. hot, *d.* sol. cold aq.; sol. hot. alcohol, less in cold;  $C_6H_5H_2N_2O_4$ , probably  $\begin{matrix} C(NHPh) \cdot CO \cdot H \\ | \\ CH \cdot CO \cdot NHPh \end{matrix}$ , [175°], form. yellowish indistinct crystals. Sol. hot, *m.* sol. cold aq. Sol. alkalis; acid. substance unchanged (Michael, *Ann.* 9, 189; *B.* 19, 1573).

**Salts.**— $Ag^+A^-$ : cry. saline pp.  $Ca^{++}A^{--}$ :  $—CaNaA^{--}$ , 4aq.  $PhA^{--}$  4aq.

*Dimethyl ether*  $A^+Me_2$ , (138° I.V.). Converted by iodine into dimethyl bromo succinate.

*Diethyl ether*  $A^+Et_2$ , (256° I.V., (110° 150°) at 25 mm. (Anschütz, *B.* 12, 228; Schacherl, *A.* 229, 91).

*Anhydride*  $C_2H_2BrO_2$ , (215° I.V.). Formed as above, and also by heating di-bromo-succinic acid with  $Ac_2O$  at 130° (Anschütz, *B.* 10, 1881). Water forms bromo-maleic acid.

*Anilide*  $C_6H_5BrN_2O_2$ , [168° 175°]. From the anilide aniline.

*Anilide*  $C_6H_5BrO \cdot NH_2$ , [151°]. Formed, together with the anilide of di-bromo-maleic acid, by heating succinimide with Br at 165° (Clemmensen, *B.* 17, 557; Kricheldorf, *Sitz.* *B.* 71, 561).

*Iso-bromo-maleic acid* is Bromo-maleic acid (*q. v.*).

**Bromo-maleic acid** (1)  $C_2H_2BrO_2$ , [112°]. From mucchloronic acid and bartha (Hill, *B.* 17, 230).  $KA^{--}$  4aq.  $PhA^{--}$  2aq.  $AgA^{--}$ .

**Di-bromo-maleic acid**  $C_2H_2Br_2O_2$ , [123°]. Formed, together with bromo-succinic acid, by brominating succinic acid (Kekulé, *A.* 130, 2). From (β)-di-bromo-pyromucic acid and from tri-bromo-pyromucic acid by Lett dibute  $HNO_3$  (Hill a. Sanger, *J.* 232, 89). Formed also by heating mucchloronic acid with Br at 140° (Hill, *Am.* 3, 48; *B.* 13, 731). Smaller needles, *v. sol.* water, alcohol, and ether, *v. sl.* sol. benzene and ligroin. An equivalent quantity of aniline added to a solution of the acid in water dissolves

and then deposits the acid aniline salt. When this is allowed to stand under water it gradually forms an anilide. The neutral salt in the same way gives the di-anilide  $C_6H_5Br \cdot CO \cdot NHPh$ , [110°]. By heating the acid (3 pts.) with water (60 pts.) and aniline (22 pts.) for 30 minutes  $C_6H_5Br \cdot CO \cdot NHPh$  [183°] is obtained in the form of flat, yellowish red prisms; *insol.* aq.; *m.* sol. hot alcohol (Michael, *Ann.* 9, 190).

**Salts.**— $BA^{++}2aq.$  8, 600 at 20°.  $PhA^{++}$  4aq.  $—AgA^{++}$ : explodes when heated.

*Anhydride*  $C_2H_2Br_2O_2$ , [110°]. Prepared by heating the acid. Needles (by sublimation); *sl.* sol. cold water.

*Anilide*  $\begin{matrix} CBr \cdot CO \\ | \\ CBr \cdot CO \end{matrix} \cdot NH_2$ , [225°]. Formed by heating succinimide with bromine. Monoclinic crystals, *anhyd.* 4342.1; 9649; *μ* 119. *an.* By boiling with aqueous KOH it is converted into di-bromo-maleic acid (Clemmensen, *B.* 17, 556; G. 14, 35; cf. Kricheldorf, *Sitz.* *B.* 71, 561).

**Bromo-maleic acid-di-bromide** *v.* Tri-bromo-succinic acid.

**DI-BROMO-MALEIC ALDEHYDE**  $C_2H_2Br_2O_2$ , [90°]. Got in small quantity from (β)-dibromo-pyromucic acid and aqueous bartha (Tomlin, *B.* 12, 1293; Hill a. Sanger, *J.* 232, 87). Long thin prisms (from water). *V. sol.* alcohol, ether, chloroform, and benzene, *m.* sol. light petroleum. In a current of  $CO_2$  it may be sublimed. On oxidation it gives mucchloronic acid.

**BROMO-MALEYL BROMIDE**  $C_2H_2Br_3O_2$ , [56°]. Formed by treating (α)-dibromo-pyromucic acid with cold bromine (Hill a. Sanger, *J.* 232, 89). Long prisms (from light petroleum).

**BROMO-MALIC ACID**  $C_2H_3BrO_2$ . The sodium salt  $NaHA^{--}$  is formed by the action of  $NaOH$  (sodium di-bromo-succinate). Boiling bartha-water converts it into calcium succinate. Sodium-amalgam forms sodium succinate.  $Ph(OAc)_2$  1 pt.  $PhA^{--}$ .

*Ethyl derivative.* Sodium salt  $CO \cdot Na \cdot CH_2 \cdot (CH_2OEt) \cdot CO \cdot Na$ . Hygroscopic mass; formed by adding alcoholic  $NaOH$  to sodium di-bromo-succinate (Muller u. Hamburger, *B.* 7, C. 1, 151).

**BROMO-MALONIC ACID**  $C_2H_2Br_2O_4$ , *i. e.*  $CHBr(CO \cdot H)_2$ . Obtained by replacing the di-brominated acid with sodium malonate, *anhyd.* *J.* *B.* 10, 65; *B.* 11, 1151. Deliquescent; moist  $Ag_2O$  forms bationic salt.  $AgHA^{--}$ .  $AgA^{--}$ .

**Di-bromo-malonie acid**  $CH_2 \cdot CO \cdot H \cdot Br \cdot CO \cdot H \cdot Br$ , [126°]. From malonic acid  $CH_2 \cdot CO \cdot H \cdot Br$  and Br (Pettrich, *B.* 7, 499; *J.* *B.* 19, 65; Van't Hoff, *B.* 8, 3.5). Needles, *v. c.* sol. water. Boiling bartha-water forms mucchloronic acid.

*Anilide*  $CBr_2 \cdot CO \cdot NH_2$ , [206°]. Formed by adding Br to malonic anilide in aqueous solution (Freund, *B.* 17, 216). Formed also by the action of alcoholic  $NH_3$  on the anilide of pentabromo-aceto-acetic acid  $CBr_3 \cdot CO \cdot Cl \cdot CO \cdot NH_2$  (Stokes a. Peckmann, *Ann.* 8, 389). Needles, prisms, or large octahedra. *Sl.* sol. hot water, alcohol, and acetic acid.  $—CBr_2 \cdot CO \cdot NH_2 \cdot Hg \cdot CO \cdot NH_2$ : white amorphous powder, insoluble in water and alcohol.

**Methylamide**  $CBr_2 \cdot CO \cdot NHMe$ , [162°];

large white needles or trimetric crystals (Freund, *B.* 17, 782).

**BROMO-MALOPHTHALIC ACID**  $C_8H_5BrO_3$ . From tetra-hydro-phthalic acid and bromine-water (Bayer, *A.* 166, 353). Prisms or tables (containing  $\frac{1}{2}$  aq.). Baryta-water converts it into  $C_8H_5O_4$ .

**BROMO-MELILOTIC ACID** v. Bromo-oxy-phenyl-meliotic acid.

#### BROMO-MESITENE LACTONE

$C_8H_5Br$   $\langle \begin{smallmatrix} O \\ \diagup \diagdown \\ CO \end{smallmatrix} \rangle$ . [105°]. From mesitene lactone,  $CS_2$  and Br (v. Aceto-acetic ether). Sl. sol. cold alcohol and water (Hantzsch, *A.* 222, 18).

**BROMO-MESITOL**  $C_8H_5BrO$  i.e.  $C_8H_5Me.Br(OH)$ . [80°]. Needles (from alcohol) (Biedermann & Ledoux, *B.* 8, 59).

**Di-bromo-mesitol**  $C_8H_3Br_2(OH)$ . [150°]. From mesitol, Br, HOAc, and I (Jacobsen, *A.* 195, 265).

**BROMO MESITYL ALCOHOL** v. Bromo- $\omega$ -oxy-mesitylene.

**p-BROMO-MESITYL BROMIDE** v. *p*- $\omega$ -Di-bromo-mesitylene.

**BROMO-MESITYLENE**  $C_8H_5Br$  [133:54]. *Bromo- $\alpha$ -tri-methyl-ben. ene.* [-1°]. (227° i. v.). S.G. 1.132. Formed by the action of 1 mol. Br upon cold mesitylene in the dark (Fittig & Storer, *A.* 147, 6; Schramm, *B.* 19, 212).

(53:1)  $\omega$ -Bromo-mesitylene  $C_8H_4(CH_3)(CH_2Br)$  [135°]. *Mesityl bromide*. [38°]. (231°). Prisms. Formed by bromination of mesitylene at 130° (Wispeck, *B.* 16, 1577; Colson, *A. Ch.* [6] 6, 89; *C. R.* 96, 713).

*iso*-Di-bromo-mesitylene  $C_8H_3Br_2$ . [64°]. (278°). Long needles. Formed by the action of 2 mols. of bromine upon mesitylene in the dark (F. a. S.; Süssenguth, *A.* 215, 218; Schramm, *B.* 19, 212). Fuming  $HNO_3$  gives bromo-di-nitro-mesitylene [194°].

*p*- $\omega$ -Di-bromo-mesitylene  $C_8H_3Br_2$  [53:4:1]. *p*-Bromo-mesityl bromide. Oil, fluid at -19°. Decomposes on distillation. Formed by the action of bromine (1 mol.) in *sunshine* upon *iso*-bromo-mesitylene (Schramm, *B.* 19, 213).

*meso*-Di-bromo-mesitylene  $C_8H_3Br_2$  [66°]. Formed by passing  $CO$ , charged with bromine vapour into boiling mesitylene (Colson, *A. Ch.* [6] 6, 92; *C. R.* 96, 713; Robinet, *C. R.* 96, 500). Formed also by treating  $\omega$ -di-oxy-mesitylene with  $HBr$  (Robinet & Colson, *Bl.* [2] 40, 111). Neg. prisms; decomposed by alcohol.

**Tri-*iso*-bromo-mesitylene**  $C_8H_3Br_3$ . [224°]. Formed by the action of 3 mols. of bromine upon mesitylene in the dark (Schramm, *B.* 19, 213). Triclinic crystals, v. sl. sol. alcohol.

*o*, $\omega$ , $\omega$ -Tri-bromo-mesitylene  $C_8H_2Br_3$  [54:3:1]. [122°]. Obtained by the action of bromine (1 mol.) in *sunshine* upon hot *p*- $\omega$ -di-bromo-mesitylene (*p*-bromo-mesityl-bromide)  $C_8H_4(CH_3)Br(CH_2Br)$ . Very slender needles (from alcohol) Schramm, *B.* 19, 215).

*c*, $\omega$ , $\omega$ -Tri-bromo-mesitylene  $C_8H_2Br_3$  [52:1:3]. [81°]. From bromo- $\omega$ , $\omega$ -di-oxy-mesitylene and conc.  $HBr$ . Can be formed by brominating mesitylene (Colson, *A. Ch.* [6] 6, 101; *Bl.* [2] 41, 362).

*o*, $\omega$ , $\omega$ -Tri-bromo-mesitylene  $C_8H_2Br_3$ . [94°]. (217°) at 10 mm. From boiling mesityl-

ene and Br (3 mols.). Needles, v. sol. boiling alcohol (Colson, *C. R.* 96, 713; *A. Ch.* [6] 6, 96).

**BROMO-MESITYLENE GLYCOL** v. Bromo-di-oxy-mesitylene.

**BROMO-MESITYLENE SULPHONIC ACID**  $C_8H_5BrSO_3H$  i.e.  $C_8H_5Me.Br.SO_3H$ . Formed by the action of bromine-water on a very dilute solution of mesitylene-sulphonic acid or its Ba salt; formed also from bromo-mesitylene and fuming  $H_2SO_4$  (Rose, *A.* 164, 56). Deliquescent trimetric needles (from ether).— $BaA'$ , aq.— $PbA'$ , 11 aq.,  $KA'$ , aq.,  $CaA'$ , aq.,  $NaA'$ .

( $\alpha$ )-BROMO-MESITYLENIC ACID  $C_8H_5BrO_2$  i.e.  $C_8H_5Me.Br(CO_2H)$  [133:15; 147°]. Formed, together with some of its isomerides, by the slow action of Br on mesitylenic acid in the cold. Formed also from the corresponding amido-mesitylenic acid (Schmitz, *A.* 193, 172). Trimetric prisms (from alcohol), *abce* = 927:1:470. —  $BaA'$ , aq.; monoclinic, *abce* = 3:068:1:801;  $\beta$  = 63° 21'— $CaA'$ , 2 aq.

( $\beta$ )-Bromo-mesitylenic acid  $C_8H_5Me.Br(CO_2H)$  [132:25; 215°] (Sch.); [212°] (S.). Formed by oxidising bromo-mesitylene (Fittig & Storer, *A.* 147, 1), or from the corresponding amido-acid (Sch.). Monoclinic crystals, *abce* = 1:193:1:760;  $\beta$  = 70° 35'.— $BaA'$ , —  $CaA'$ ,  $CaA'$ , 5 aq.,  $KA'$ .

**Di-bromo-mesitylenic acid**  $C_8H_3Br_2Me_2(CO_2H)_2$ . [195°]. Formed by oxidising di-bromo-mesitylene (Süssenguth, *A.* 215, 250). Needles (by sublimation).— $CaA'$ , 7 aq.;— $BaA'$ , 31 aq.

**BROMO-METHACRYLIC ACID**  $C_8H_5BrO_2$  i.e.  $CHBr.CMe.CO_2H$ . *Bromo-crotonic acid*. [63°]. (229°). From *citra*- or *mesa*-di-bromo-pyrotartaric acid by treatment with water,  $Na_2CO_3$  aq., or  $KOH$  aq. (Kekulé, *A. Suppl.* 2, 97; Cahours, *A. Suppl.* 2, 317; Fittig & Krusmark, *A.* 206, 7; Friedrich, *A.* 203, 354). Also from *at*-di-bromo-isobutyric acid and  $NaOH$  aq. (C. Kolbe, *J. pr.* [2] 25, 382). Flat needles, sl. sol. cold water. Reduced by sodium amalgam to isobutyric acid. Decomposed by heating with alkalis into methane, allylene, and acetic acid (F.).— $CaA'$ , 3 aq. S. (of  $CaA'$ ) 575 at 11°.— $AgA'$ .— $HIO$ ,  $CaA'$ .  $NH_4HA'$  (Morawski, *Sitz.* B. 74, 39).

*Ethyl ether*  $EAc$ . (193°) (C.).

**Bromo-methacrylic acid**  $CH_2=C(CH_2Br)CO_2H$ . [66°]. Formed, together with the preceding, by boiling *mesa*-di-bromo-pyrotartaric acid with water or  $Na_2CO_3$  aq. (Krusmark, *A.* 206, 12). Laminae (from water), v. sol. water; volatile with steam. Reduced with difficulty by sodium amalgam to isobutyric acid.— $CaA'$ , 2 aq. S. (of  $CaA'$ ) 80 at 5°.

**Di-bromo-methacrylic acid**  $C_8H_3Br_2O_4$ . Needles. From tri-bromo-butyric acid (dibromide of bromo-methacrylic acid). At 120° it takes up Br forming tetra-bromo-butyric acid, whence boiling alkalis form

**Tri-bromo-methacrylic acid**  $C_8H_2Br_3O_4$ . Needles (C.).

**BROMO-METHANE** v. METHYL BROMIDE.

**Di-bromo-methane** v. METHYLENE BROMIDE.

**Tri-bromo-methane** v. BROMOFORM.

**Tetra-bromo-methane**  $ClBr_3$ . *Carbon tetra-bromide*. [92°]. (189°). Occurs in commercial bromine (Hamilton, *C. J.* 39, 48).

**Formation.**—1. By heating Br with  $CS_2$  in presence of I or  $SbBr_3$  (Bolas & Groves, *C. J.* 23, 161; 24, 773; *A.* 156, 60; 160, 160).—2.

From  $\text{CH}_2\text{Cl}_2$  and  $\text{IBr}_2$  (Höland, A. 240, 236).—  
8. From alcohol and Br (Schäffer, B. 4, 386).—  
1. By exposing a mixture of dilute KOH, bromoform, and Br to sunlight (Habermann, A. 167, 174).—5. By heating bromoform or bromopierin with  $\text{SbBr}_3$  or  $\text{BrI}$  at  $150^\circ$ .—6. From  $\text{Cl}_2$  and Br (Gustavson, A. 172, 176).—7. From  $\text{CCl}_4$  and  $\text{Al Br}_3$  at  $100^\circ$  (Gustavson, J. R. 13, 286).  
8. From  $\text{CH}_3\text{Br}$  and Br in presence of animal charcoal (Damoisson, C. R. 92, 421).

**Preparation.**— $\text{CS}_2$  (2 pts.) is heated with iodine (3 pts.) and Br (14 pts.) for 96 hours at  $150^\circ$  (Höland, A. 240, 238).

**Properties.** Tablets with faint camphor like smell; extremely prone to sublimation. At  $220^\circ$  it splits up into  $\text{CBr}_4$  and bromine. Boiling alcohol gives bromal,  $\text{HBr}$ , and aldehyde. Alcoholic KOH gives  $\text{K}_2\text{CO}_3$  and  $\text{KBr}$ . Sodium amalgam forms  $\text{CHBr}_3$  and  $\text{CH}_2\text{Br}_2$ .

**BROMO METHANE DI-SULPHONIC ACID**  $\text{CHBr}_2\text{SO}_2\text{H}$ . Potassium salt  $\text{K}^+$ . From bromo-di-sulphoaldehyde  $\text{CHBrSO}_2\text{H}\cdot\text{CHO}$  by boiling with aqueous  $\text{K}_2\text{CO}_3$  (Rathke, J. 161, 161).

**Di bromo methane sulphonic acid**  $\text{CHBr}_2\text{SO}_2\text{H}$ . Barium salt  $\text{Ba}^{++}$ . Thin metallic plates, formed by the action of Br upon barium sulphonic acid at  $130^\circ$  (Amberg, M. 7, 157).

**BROMO PENTA METHYL-TRI AMIDO TRI-PHENYL-CARBINOL**  $\text{C}_6\text{H}_5\text{BrN}_3\text{O}$ . Hydrobromide  $\text{C}_6\text{H}_5\text{BrN}_3\text{O}\cdot\text{HBr}$ . Formed by heating di-methyl-aniline with Br at  $120^\circ$  (Brandenburg, a. Brunner, B. 10, 1845, 11, 697).

**DI-BROMO-METHYLAMINE**  $\text{MeNBr}_2$  v. Methylamine.

**p-BROMO-METHYL ANILINE**  $\text{C}_6\text{H}_4\text{BrNHMe}$  (H. 1). (250). Prepared from the nitro-amine.

**Acetyl derivative** 99. **Nitrosamine**  $\text{C}_6\text{H}_4\text{BrNMe(NO)}$  (71). Long needles. Formed by the action of  $\text{HNO}$  on p-bromo-di-methyl-aniline (Wurster a. Scheib, B. 12, 1818).

**m-Bromo-di-methyl-aniline**  $\text{C}_6\text{H}_3\text{BrNMe}_2$  (13). (112). (264 corr.). Prepared by the methylation of m-bromaniline. By the action of  $\text{HNO}$  it gives a nitroso compound which forms light green needles and melts at about  $118^\circ$ .

**Methylo-iodide**  $\text{C}_6\text{H}_3\text{BrNMe}_2\text{I}$  (201). Leaflets (Wurster a. Scheib, B. 12, 1818).

**p-Bromo-di-methyl-aniline**  $\text{C}_6\text{H}_4\text{BrNMe}_2$  (11). (55). (264 corr.).

**Preparation.** 1. By bromination of di-methyl-aniline dissolved in acetic acid (Wurster, B. 8, 714; 10, 763). 2. By methylation of p-bromaniline. By the action of  $\text{HNO}$  it gives a mixture of p-nitro-di-methyl-aniline and p-bromo-pharyl-methyl-nitro-amine.

**Methylo-iodide**  $\text{C}_6\text{H}_3\text{BrNMe}_2\text{I}$  (185) (Wurster a. Scheib, B. 12, 1816).

**Ferrocyanide**  $\text{B}_3\text{H}_3\text{Fe(CN)}_6\cdot\text{aq}$ ; **very soluble yellow crystals** (Wurster a. Reser, B. 12, 1825).

**BROMO-DI-METHYL-ANILINE-PHTHALEIN**  $\text{C}_{12}\text{H}_8\text{Br}_2\text{N}_2\text{O}_2$  v.

$\text{C}_6\text{H}_4\text{Br}_2\text{N}_2\text{O}_2$ . The hydrochloride,  $\text{C}_6\text{H}_4\text{Br}_2\text{N}_2\text{O}_2\cdot\text{HCl}$ , formed by heating p-bromo-di-methyl-aniline with phthalyl chloride, crystallises in colorless needles. Conc.  $\text{HCl}$  aq. precipitates  $\text{B}_3\text{H}_3\text{FeCl}_6$  (O. Fischer, D. 10, 1623).— $\text{B}_3\text{H}_3\text{FeCl}_6$ .

## DI-BROMO-METHYL-ANTHRACENE

$\text{C}_{14}\text{H}_8\text{Br}_2$ . ( $138^\circ$ - $140^\circ$ ). From methyl-anthracene by Br in  $\text{CS}_2$  (Liebemann, A. 212, 85). Yellow needles (from glacial HOAc).

**Tetra-bromo-methyl-anthracene**  $\text{C}_{14}\text{H}_4\text{Br}_4$ . Needles (from toluene). Oxidises to di-bromo-methyl-anthraquinone (L.).

**DI-BROMO-DI-METHYL-ANTHRACENE-DIHYDRIDE**  $\text{C}_{14}\text{H}_{10}\text{Br}_2$ . From di-methyl-anthracene dihydride and Br in HOAc (Anschütz, A. 235, 399). Oxidises to anthraquinone.

**DI-BROMO METHYL-ATROLACTIC ACID** v. Di-bromo-oxymethyl-propionic acid.

**TETRA-BROMO-METHYL-AURINE**  $\text{C}_6\text{H}_4\text{Br}_4\text{O}$ . Formed by brominating methyl-aurine— $\text{R}^+\text{HBr} \cdot 2\text{aq}$  (Zukowsky, M. 3, 471).

**BROMO-METHYL-BENZENE** v. Bromo-toluene.

**Bromo-di-methyl-benzene** v. Bromo-xylene. **Tri-bromo-tri-methyl-benzene**  $\text{C}_6(\text{CH}_3)_3\text{Br}_3$  (1223; 1536). **Tri-bromo-hexamethylthene** (245). Needles. Sol. alcohol. Formed by bromination of (1,2,3)-tri-methyl-benzene (Jacobsen, B. 15, 1858). Other bromo-tri-methyl-benzenes are described as bromo- $\psi$ -cumenes and bromo-mstylenes.

**Bromo-tetra-methyl-benzene** v. Bromo-purane.

**Bromo-penta-methyl-benzene**  $\text{C}_6\text{BrMe}_5$  (161). (239). From  $\text{C}_6\text{Me}_5\text{H}$ , Br, and I (Friedel a. Crafts, A. Ch. [6] 1, 473).

**Hexa- $\alpha$ -bromo-hexa-methyl-benzene**  $\text{C}_6(\text{CH}_3)_6\text{Br}_6$  (255) (F. a. C.); (227) (H.). From hexa-methyl-benzene, water, and Br at  $100^\circ$  (Hofmann, B. 13, 1732; Friedel a. Crafts, J. Ch. [6] 1, 468).

**BROMO-METHYL-BENZOIC ACID** v. Bromo-toluic acid.

**Bromo-di-methyl-benzoic acid**  $\text{C}_6\text{H}_3\text{BrMe}_2\text{CO}_2\text{H}$  (173). **Bromo-pseudo-cumelic acid**. **Bromo-xylylic acid**. From  $\text{C}_6\text{H}_3\text{BrMe}_2$  (1224; 5) by  $\text{O}$ , in HOAc (Sis-enuth, A. 215, 241). Also from  $\text{C}_6\text{H}_3\text{Me}_2(\text{CO}_2\text{H})$  (133) and Br (Ganter, B. 17, 1608). Needles (from water). V. c. sol. alc. sol.  $\text{Ca}^{++}$ , 2aq.  $\text{Ba}^{++}$ , 6aq.

**Bromo-di-methyl-benzoic acid**  $\text{C}_6\text{H}_3\text{BrMe}_2\text{CO}_2\text{H}$  (189). **Bromo-xylylic acid**. From  $\text{C}_6\text{H}_3\text{Me}_2(\text{CO}_2\text{H})$  (124) and Br (Ganter, B. 17, 1609). Needles (from dilute alcohol).

Other isomerides are described v. Bromo-mstylenic acids (q. v.).

## eco-BROMO-DI-METHYL-COUMARIN

$\text{C}_6\text{H}_4(\text{CH}_3)_2\text{C}(\text{CH}_2\text{Br})\text{CO}$ . Formed by bromina-

tion of di-methyl-coumarin dissolved in  $\text{CS}_2$ . Crystalline solid. Sol. alcohol. Converted by hot alcoholic KOH into di-methyl-coumarilic acid (di-methyl-ecoumarone-carboxylic acid) (Hantzsch a. Laug, B. 13, 1299).

**DI-BROMO-METHYLENE-DI-PHENYLENE**  $\text{C}_{12}\text{H}_8\text{Br}_2$  (162). From methylene-di-phenylene (q. v.). Needles or octahedra (from ether) (Carbonyl, C. J. 37, 710).

**HEXA-BROMO-METHYLENE-DI-PHENYLENE OXIDE**  $\text{C}_{12}\text{H}_4\text{Br}_6\text{O}$ . Formed, together with the hepta-brominated compound  $\text{C}_{12}\text{H}_3\text{Br}_7\text{O}$  (136), by adding Br to o-methylene-di-phenylene oxide suspended in water. Blackens at c.  $225^\circ$  (Salzmann a. Wichehaus, B. 19, 1401).

**BROMO-METHYLENE-PHTHALIDE**

$C_6H_3BrO_2$ , i.e.  $C_6H_4 \begin{matrix} \diagup C=CHBr \\ \diagdown O \\ \diagup C=O \end{matrix}$ . [133°]. Long

colourless needles. Formed by heating phthalyl-bromo-acetic acid *in vacuo*; or by bromination of acetophenone-carboxylic acid. It combines with  $Br_2$  forming  $C_6H_4 \begin{matrix} \diagup CBr(CBr.H) \\ \diagdown CO \end{matrix} > O$ . [118°] (Gabriel, *B.* 17, 2525).

**p-BROMO-METHYL-ETHYL-ANILINE**

$C_9H_{11}BrN$  i.e.  $C_6H_4Br.NMeEt$ . (265°). From methyl-ethyl-aniline and  $Br$ . Solidifies below 0° (Claus a. Howitz, *B.* 17, 1327).

**TRI-BROMO-DI-METHYL-ETHYL-BENZ-ENE**  $C_{10}H_{11}Br_3$  i.e.  $C_6Br_3Me_2Et$ . [218°]. (Jacobsen, *B.* 7, 1434).

**DI-BROMO-METHYL-ETHYL-GLYOXALINE**  $C_3Br_2(CH_3)(C_2H_5)N_2$ . *Di-bromo-oxal-ethyl-ine*. [38°]. Colourless crystals. Sol. acids. Formed by bromination of methyl-ethyl-glyoxal-ine (oxal-ethyl-ine) (Wallach, *B.* 16, 537).

**HEXA-BROMO-METHYL-ETHYL-KETONE**  $C_{11}H_2Br_6O$  i.e.  $CBr_2.CO.CH_2.CBr_2$ . [90°]. From  $\alpha$ -di-bromo-ethylene and  $HBrO$  (Demole, *B.* 11, 1710). Reduced by sodium-amalgam to methyl ethyl ketone. Fuming  $HNO_3$  gives malonic acid.

**DI-BROMO-(B, 2-Py, 2)-DI-METHYL-(Py, 3)-ETHYL-QUINOLINE**  $C_{13}H_{12}Br_2N$ . [144°]. White needles (Harz, *B.* 18, 3389).

**TRI-BROMO-METHYL-GLYOXALINE**

$C_3Br_3(CH_3)N_2$ . *Tri-bromo-oxal-methyl-ine*. [89°]. White crystals. Insoluble in cold water.

*Formation*.—1. By the action of  $MeI$  on tri-bromo-glyoxal-ine-silver. —2. By bromination of methyl-glyoxal-ine (oxal-methyl-ine) dissolved in dilute  $H_2SO_4$  (Wallach, *B.* 16, 537).

**BROMO-METHYL-INDONAPHTHENE-CARBOXYLIC ACID**  $C_9H_4 \begin{matrix} \diagup CBrMe \\ \diagdown CH \end{matrix} > C.CO_2H$ . [215°].

Formed by bromination of methyl-indonaphthene in chloroform. Needles. Sol. alcohol (Roser, *B.* 20, 1575).

**HEXA-BROMO-DI-METHYL-METHYLENE DIKETONE**  $C_{12}H_2Br_6O_2$  i.e.  $CBr_2.CO.CH_2.CO.CBr_2$ . *Hexa-bromo-acetyl-acetone*. [108°]. From the diketone and  $Br$  (Combes, *A. Ch.* [6] 12, 210). Needles; decomposed by alkalis into tri-bromo-methylene and tri-bromo-acetic acid.

**endo-a-METHYL-NAPHTHALENE**

$C_{10}H_7Br(CH_3)$ . (298° corr.). Colourless fluid. Formed by the action of bromine on a cold solution of (a)-methyl-naphthalene in  $CS_2$ .

*Picric acid compound*. [95°]. Yellow needles  $C_{11}H_7Br.C_6H_3(NO_2)_3OH$ . (Schulze, *B.* 17, 1528).

*endo-Bromo-β-methyl-naphthalene*. Formed  $C_{10}H_7Br(CH_3)$ . (296°). Colourless fluidation of by the action of bromine on a cold solution of (β)-methyl-naphthalene in  $CS_2$ .

*Picric acid compound*  $C_{11}H_7Br.C_6H_3(NO_2)_3OH$  [113°], yellow needles (Schulze, *B.* 17, 1528).

**ω-Bromo-(β)-methyl-naphthalene**

$C_{10}H_7.CH_2Br$ . [56°]. (213° at 100 mm.). White glistening plates. Formed by passing gaseous bromine into (β)-methyl-naphthalene heated to 240° (Schulze, *B.* 17, 1529).

**Tri-bromo-di-methyl-naphthalene**  $C_{12}H_8Br_3$ . [228°] (Cannizzaro a. Carnelutti, *G.* 12, 410; cf. Giovanozzi, *G.* 12, 147).

**TRI-BROMO-METHYL-DI-PHENYL-AMINE**

$C_{13}H_{10}Br_3N$  i.e.  $NMe(C_6H_5Br)_2(C_6H_5Br)$ . [98°]. From methyl-di-phenyl-amine and  $Br$  (Gnehm, *B.* 8, 926).  $HNO_3$  forms  $\{C_6H_4Br(NO_2)\}_2NH$ .

**Tetra-bromo-methyl-di-phenyl-amine**

$(C_6H_4Br)_2NMe$ . [129°]. Formed at the same time as the preceding (G.).

**DI-BROMO-DI-METHYL-QUINOL v. Di-methyl-Bromo-Hydroquinone.**

**BROMO-METHYL-PIPERIDINE**

$CH_2 \begin{matrix} \diagup CBr.CH_2 \\ \diagdown CH_2.CH_2 \end{matrix} > NMe$ . The methyl-bromide ( $B'MeBr$ ) is formed very readily by isomeric change of di-methyl-εδ-di-bromo-*n*-amyl-amine (so-called 'di-methyl-piperidine-di-bromide'),  $CH_2Br.CHBr.CH_2.CH_2.CH_2.NMe_2$ , by warming its alcoholic solution for a short time (Merling, *B.* 19, 2630).

**DI-BROMO-METHYL-PYRIDINE**  $C_6H_5Br_2N$  i.e.  $C_5NH_4MeBr_2$ . [109°]. Formed, together with ethylene bromide, from tropidine (*q. v.*) hydrobromide and bromine at 165° (Ladenburg, *A.* 217, 145).

*s*-Di-bromo-di-methyl-pyridine  $C_5NHMe_2Br_2$  [1:5:2:4]. *Di-bromo-lutidine*. [65°]. Formed by the action of bromine upon an aqueous solution of the potassium salt of *s*-di-methyl-pyridine-di-carboxylic acid. —  $B_2H_4.Cl_2.PtCl_2$  2aq: needles (Pfeiffer, *B.* 20, 1350).

Di-bromo-*s*-tri-methyl-pyridine  $C_5NMe_3Br_2$  [1:3:5:2:4]. *Di-bromo-collidine*. [81°]. (262°) at 726 mm. Obtained by the action of bromine upon an aqueous solution of the potassium salt of *s*-tri-methyl-pyridine-di-carboxylic acid; the yield is 50 p.c. of the theoretical. White pearly plates. Very volatile with steam. Weak base.

Salts.— $B'HCl$ : easily soluble small glistening crystals.  $B'_2H_4.Cl_2.PtCl_2$  2aq: orange-yellow needles.  $B'_2H_4.CrO_3$ : [146°]; needles. —  $B'_2C_6H_4(NO_2)_2.OH$ : [160°] dark-yellow flat prisms, v. sol. hot alcohol, insol. water (Pfeiffer, *B.* 20, 1345).

**DI-BROMO-TRI-METHYL-PYRIDINE DI-CARBOXYLIC ETHER. Dibromide**  $NC_5H_2Br_2(CO_2Et)_2$ . [102°]. From the following body and fuming  $HNO_3$  (Hantzsch, *A.* 215, 17).

**Di-bromo-tri-methyl-pyridine di-carboxylic ether. Di-bromhydride**

$NC_5H_2Br_2(CO_2Et)_2$ . [88°]. From the dihydride of (1,3,5,2,4)-tri-methyl-pyridine-di-carboxylic ether by  $Br$  in  $CS_2$  (Hantzsch, *A.* 215, 14). Yellow twin crystals.

**DI-BROMO-DI-METHYL-PYROCATECHIN v. Di-methyl ether of Di-bromo-pyrocatechin.**

**HEXA-BROMO-DI-METHYL-TRISULPHIDE**  $C_2Br_3S_2$  i.e.  $(CBr_3)_2S_2$ . *Carbotriethiohexabromide*. [125°]. S. (alcohol) 5:5 at 78°; S. (ether) 2:35 at 0°. From  $CS_2$  and  $Br$  (Hell a. Urech, *B.* 15, 275, 987; 16, 1147). Prisms or tables, insol. water. Hot conc.  $NaOH$  gives  $NaBr$ ,  $Na_2CO_3$ , and  $Na_2S$ . Decomposed by heat into  $CBr_3$ ,  $CS_2Br_2$ ,  $SiBr_3$ , and a blue substance  $C_2Br_3S_2$  2aq.

**DI-BROMO-METHYL-THIOPHENE**

$HBBr_2(CH_3)S$ . (228°). Oil (Meyer a. Kreis, *B.* 1787).

*Di-bromo-(a)-methyl-thiophene*  $C_4Br_2(CH_3)S$ . *Di-bromo-(β)-thiophene*. [86°]. Formed by bromination of (β)-methyl-thiophene (Egli, *B.* 18,

545). Long colourless silky needles. V. sol. ether and hot alcohol.

**Tri-bromo-methyl-thiophene**  $C_4Br_3(CH_3)S$ . [39°]. Formed by bromination of the methyl-thiophene from pyrotartaric acid. Large colourless needles (Volhard a. Erdmann, *B.* 18, 455). Forms a molecular compound [74°] with the preceding (Gattermann, *B.* 18, 3005).

**Bromo-di-methyl-thiophene**  $C_4H(CH_3)_2BrS$ . **Bromo-thioxene**. [194° uncor.]. Formed by bromination of thioxene dissolved in  $CS_2$ . Volatile with steam. Colourless fluid. Heavier than water (Messinger, *B.* 18, 1637).

**Di-bromo-di-methyl-thiophene**  $C_4(CH_3)_2Br_2S$ . **Di-bromo-thioxene**. [46°]. (217° uncor.). Long colourless needles. Formed by adding 2 mols. of bromine to cooled thioxene (from coal-tar) (Messinger, *B.* 18, 563).

**Di-bromo-di-methyl-thiophene**  $C_4(CH_3)_2Br_2S$ . **Di-bromo-thioxene**. [47° 50°]. Needles. Volatile with steam. Formed by bromination (with  $2Br_2$ ) of the thioxene (from acetyl-acetone) (Paal, *B.* 18, 2253).

**Tri-bromo-di-methyl-thiophene**  $C_4H_2Br_3S$  i.e.  $C_4Br_2(CH_3)(CH_2Br)S$ . **Tri-bromo-thioxene**. [141°]. Crystallises and sublimes in needles. Formed by the action of an excess of bromine upon the di-bromo- derivative of the thioxene obtained from acetyl-acetone (Paal, *B.* 18, 2253).

**Octo-bromo-di-methyl-thiophene**  $C_4Br_8(CH_3)_2S$ . **Octo-bromo-thioxene**. [114°]. Small needles. Formed by the action of an excess of bromine upon thioxene (from coal-tar) (Messinger, *B.* 18, 565).

**BROMO-DI-METHYL-o-TOLUIDINE**  $C_9H_7BrN$  i.e.  $C_9H_4(CH_3)_2(Br)NMe_2$ . [245°]. Prepared by bromination of di-methyl-o-toluidine, or by methylation of bromo-o-toluidine (Michler a. Sampaio, *B.* 14, 2172). Liquid; sol. alcohol and ether, volatile with steam.

**Bromo-di-methyl-m-toluidine**  $C_9H_7(Br)(CH_3)_2NMe_2$ . [1:2:4]. [98°]. (276°). Prepared by bromination of di-methyl-m-toluidine. White leaflets. Insol. water, sol. alcohol, ligroin and  $C_6H_6$  (Wurster a. Riedel, *B.* 12, 1800).

**Ferrocyanide**  $B_3H_4Fe(CN)_4aq$ : crystals. **Ferricyanide**  $B_3H_4Fe_2(CN)_{12}aq$ . Very soluble yellow crystals (Wurster a. Roser, *B.* 12, 1826).

**TETRA-BROMO-MYRISTIC ACID**  $C_{14}H_2Br_4O_2$ . From myristic acid and Br (Masino, *A.* 202, 176).

**DI-BROMO-MYRISTIC ACID**  $C_{14}H_2Br_2O_2$ . Obtained by gently warming the preceding (M.). **a-BROMO-NAPHTHALENE**  $C_{10}H_7Br$  [1]. [5°]. (277°). (280° cor.) (Ramsay a. Young, *C. J.* 47, 650). S.G.  $d_4^{20}$  1.4750;  $d_4^{25}$  1.503.  $R_{\infty}$  84.9 (Nasini, *G.* 15, 93).

**Formation**.—1. From naphthalene in  $CS_2$  and Br (Laurent, *A. Ch.* [2] 59, 196; Glaser, *A.* 135, 40; Wahlforss, *Z.* 1865, 3; Gnehm, *B.* 15, 2721).—2. From diazo-bromo-naphthalene salts by boiling with alcohol (Rother, *B.* 4, 851; Stallard, *C. J.* 49, 188).—3. From  $Hg(C_{10}H_7)_2$  and Br (Otto, *A.* 147, 175).

**Properties**.—Liquid, insol. water, miscible with alcohol, ether, and benzene.

**Reactions**.—1.  $CrO_3$  gives phthalic acid (Beilstein a. Kurbatow, *C. C.* 1881, 359).—2. A solution in  $CS_2$  gently heated with  $AlCl_3$  gives (a)-bromo-naphthalene as the chief product, to-

gether with di-bromo-naphthalenes, and naphthalene (Roux, *Bl.* [2] 45, 510).—3. Toluene in presence of  $AlCl_3$  forms bromo-toluene and naphthalene (Roux).—4. Reduced by sodium-amalgam to naphthalene.—5.  $Cl.CO_2Et$  and Na give naphthoic acid.

**Picric acid compound**  $C_{10}H_7BrC_6H_3(NO_2)_3OH$ . [135°]. Yellow needles (Wichelhaus, *B.* 2, 305; R.).

**Dichloride**  $C_{10}H_7BrCl_2$ : [165°]; tables. **(b)-Bromo-naphthalene**  $C_{10}H_7Br$  [2]. [59°]. (282 cor.). S. (92 p.c. alcohol) 6 at 20°.

**Formation**.—1. By heating (b)-diazo-naphthalene with a large excess of  $HBr$  (Gasiorowski a. Wayss, *B.* 18, 1911; cf. Liebermann, *A.* 183, 268). 2. By running a solution of (b)-diazo-naphthalene bromide into a hot solution of cuprous bromide; the yield is 30 p.c. of theoretical (Jellmann a. Remy, *B.* 19, 811).—3. From (b)-naphthol and  $PBr_3$  (Brunel, *B.* 17, 1179).—4. From (a)-bromo-naphthalene and  $AlCl_3$  (Roux, *Bl.* [2] 45, 513).

**Properties**.—Trimetric scales, v. sol.  $CS_2$ ,  $CHCl_3$ , benzene, and ether.

**Picric acid compound**  $C_{10}H_7BrC_6H_3(NO_2)_3OH$ . [79°] (R.); [86°] (B.); S. (alcohol of 92 p.c.) 6 at 20° (R.).

**Di-bromo-naphthalene**  $C_{10}H_6Br_2$ . [61°]. Formed in small quantity by brominating naphthalene (Jolin, *Bl.* [2] 28, 514; not observed by others).

**o-Di-bromo-naphthalene**  $C_{10}H_6Br_2$  [1:2]. [63°]. From (1, 2)-bromo-(b)-naphthylamine by the diazo-perbromide reaction (Meldola, *C. J.* 43, 5). Oblique rhombic prisms (from alcohol, acetone or petroleum).

**m-Di-bromo-naphthalene**  $C_{10}H_6Br_2$  [1:3]. [64°]. From di-bromo-(a)-naphthylamine, [119°] by removal of  $NH_2$  (Meldola, *C. J.* 43, 2). Needles.

**Di-bromo-naphthalene**  $C_{10}H_6Br_2$  [2:3]? [c. 68°]. Formed, together with two isomerides, [81°] and [150°] by the action of Br (2 mols.) on naphthalene (1 mol.) (Guaracchi, *G.* 7, 24). Also from bromo-(b)-naphthol and  $PBr_3$  (Canzoneri, *G.* 12, 425). Prisms (from alcohol).

**(aβ)-Di-bromo-naphthalene**  $C_{10}H_6Br_2$  [4:2' or 3']. [74°]. From (1, 2' or 3', 2)-di-bromo-naphthylamine by diazo- reaction (Meldola, *C. J.* 47, 513). Silvery scales (from dilute alcohol).

**η-Di-bromo-naphthalene**  $C_{10}H_6Br_2$  [1:1']. [77°]. Formed, together with the isomeride [1''], by brominating naphthalene (a)-sulphonic acid (Darmsäcker a. Wichelhaus, *J.* 152, 304).

**(β)-Di-bromo-naphthalene**  $C_{10}H_6Br_2$  [1:4]. [82°]. (310°). S. (93.5 per cent. alcohol) 1.33 at 11.4°; 6 at 56° (Guaracchi, *A.* 222, 269).

**Formation**.—1. The chief product of the action of bromine (2 mols.) on naphthalene (Glaser, *A.* 135, 40).—2. By distilling (a)-bromo-naphthalene sulphonic acid or nitro-(a)-bromo-naphthalene [85°] with  $HBr$  (Jolin, *Bl.* [2] 28, 514).—3. From acetyl-(a)-naphthylamine by brominating, saponifying, and treating the resulting  $C_{10}H_7Br(NH_2)$  by the diazo-reaction (Meldola, *C. J.* 43, 4).

**Properties**.—Long needles. Oxidised by  $HNO_3$  to di-bromo-phthalic and bromo-nitro-phthalic acids and bromo-nitro-naphthalene.  $CrO_3$  in acetic acid gives di-bromo-naphtho-quinone and di-bromo-phthalide. Reacts with

Br forming  $C_{10}H_7Br_2$  [173°] (Guareschi, *G.* 16, 141).

**Constitution.**—This follows from the oxidation to di-bromo-phthalic acid, coupled with the observation that the bromo-( $\alpha$ )-naphthylamine from which it may be formed (*v. supra*) gives ( $\alpha$ )-bromo-naphthalene by the diazo-reaction.

( $\gamma$ ) Di-bromo-naphthalene

$C_{10}H_6Br_2$  [1:1' or 4']. [181° cor.]. (326°). S. (93.5 p.c. alcohol) 2 at 56°.

**Formation.**—1. By brominating naphthalene (*G.*; Magatti, *G.* 11, 357).—2. From diazo-bromo-naphthalene (from bromo-naphthylamine [64°]) by adding bromine-water and warming the pp. with HOAc.—3. The chief product of the action of Br on naphthalene ( $\alpha$ )-sulphonic acid (Darmstädter a. Wichelhaus, *A.* 152, 303).—4. By the action of  $PBr_3$  on ( $\alpha$ )-di-nitro-naphthalene or bromo-naphthalene ( $\alpha$ )-sulphonic acid (*J.*).

**Properties.**—Tables.  $HNO_3$  gives bromo-nitro-phthalic acid.  $CrO_3$  in HOAc gives bromo-phthalic acid [176°]. Does not form a tetra-bromide with Br.

$\delta$ -Di-bromo-naphthalene  $C_{10}H_6Br_2$  [141°]. From naphthalene ( $\alpha$ )-sulphonic acid and  $PBr_3$  (*J.*). Thin plates.

$\epsilon$ -Di-bromo-naphthalene  $C_{10}H_6Br_2$  [160°]. From ( $\alpha$ )-bromo-naphthalene sulphonic acid and  $PBr_3$  (*J.*).

Di-bromo-naphthalene tetra-chloride  $C_{10}H_4Br_2Cl_4$  [156°]. From di-brominated naphthalene (?) [82°] and Cl (Laurent).

Di-bromo-naphthalene tetra-bromide  $C_{10}H_4Br_6$ . A mixture of three bodies of this composition, [c. 100°] [120°] and [173°] is formed from naphthalene and Br (*G.*).

Tri-bromo-naphthalene  $C_{10}H_5Br_3$  [75°]. Formed by brominating naphthalene, or by heating di-bromo-naphthalene tetra-bromide with alcoholic KOH (Laurent, *A. Ch.* [2] 59, 196; Glaser, *A.* 135, 43). Needles (from alcohol).

Tri-bromo-naphthalene  $C_{10}H_5Br_3$  [1:4:1']. [85°]. From di-bromo-nitro-naphthalene [115°] and  $PBr_3$  (Jolin). Needles.

Tri-bromo-naphthalene  $C_{10}H_5Br_3$  [87°]. From di-bromo-naphthalene ( $\beta$ )-sulphonic acid and  $PBr_3$  (*J.*). Needles.

Tri-bromo-naphthalene  $C_{10}H_5Br_3$  [1:3:1' or 4']. [105°]. From (3, 1' or 4', 1)-di-bromo-naphthylamine [102°] by diazo-reaction (Meldola, *C. J.* 47, 516).

Tri-bromo-naphthalene  $C_{10}H_5Br_3$  [1:3:2' or 3']. [110°]. From (1, 2' or 3', 3)-di-bromo-naphthylamine by the diazo-reaction. Needles (from alcohol) (Meldola, *C. J.* 47, 513).

Tri-bromo-naphthalene  $C_{10}H_5Br_3$  [1:2:4]. [114°]. From  $C_{10}H_7(NH_2)Br_2$  [1:2:4] by diazo-reaction (Meldola, *C. J.* 43, 4). Formed also by heating  $C_{10}H_5(NH_2)(NO_2)Br$  [1:2:4] with conc.  $HBrAq$  and glacial  $HNO_3$  at 130° (Prager, *B.* 18, 2163). White needles (from dilute  $C_2H_5O_2$ ). Dilute  $HNO_3$  at 180° gives phthalic acid.

Tetra-bromo-naphthalene  $C_{10}H_4Br_4$  [1:4:2:3']. [175°]. S. (95 p.c. alcohol) 5 at 78°. From di-bromo-naphthalene tetrabromide [173°] and NaOEt (Guareschi, *G.* 16, 141). Needles (from alcohol) or plates (by sublimation).  $CrO_3$  in HOAc gives di-bromo-phthalide [188°] and tetra-bromo-( $\alpha$ )-naphthoquinone [224°].

Tetra-bromo-naphthalene  $C_{10}H_4Br_4$  [120°]. From di-bromo-naphthalene tetrabromide [100°] and NaOEt (*Gu.*). Needles (from alcohol).

Tetra-bromo-naphthalene tetra-bromide  $C_{10}H_4Br_4$  [173°]. From (1, 4)-di-bromo-naphthalene and Br (*Gu.*).

Penta-bromo-naphthalene  $C_{10}H_3Br_5$ . From  $C_{10}H_5Br$  and Br at 150° (Glaser). Granules, insol. alcohol.

Hexa-bromo-naphthalene  $C_{10}H_2Br_6$  [252°]. From naphthalene, Br, and I at 400° (Gessner, *B.* 9, 1505). Also from naphthalene (20 g.),  $Al_2Cl_6$  (15 g.) and Br (300 g.) (Roux, *Bl.* [2] 45, 515). Needles; easily sublimed. Does not combine with picric acid.

**BROMO-NAPHTHALENE DI-CARBOXYLIC ACID**  $C_{12}H_8BrO_4$  i.e.  $C_{10}H_6Br(CO_2H)_2$ . [210°]. From bromo-acenaphthene and  $CrO_3$  (Blumenthal, *B.* 7, 1095). Needles (from benzene). Converted by  $NH_3$  into the imide  $C_{10}H_5Br(CO)_2NH$  [above 265°].

**BROMO-NAPHTHALENE-( $\beta$ )-SULPHINIC ACID**  $C_{10}H_7BrSO_2H$ . From naphthalene ( $\beta$ )-sulphonic acid and Br (Gessner, *B.* 9, 1503).

( $\alpha$ )-BROMO-NAPHTHALENE SULPHONIC ACID  $C_{10}H_7Br(SO_3H)$  [1:4]. [139°]. Formed by sulphonating ( $\alpha$ )-bromo-naphthalene (Laurent, *Compt. chim.* 1849, 392; Darmstädter a. Wichelhaus, *A.* 152, 303; Otto, *A.* 147, 184). Flat needles. Oxidised by  $KMnO_4$  to phthalic acid (Meldola, *B.* 12, 1964). Potash-fusion gives no bromo-naphthol (*M.*). Br gives chiefly  $C_{10}H_6Br_2$  [82°].— $CaA'$  3aq.— $BaA'$  2aq.— $PbA'$  1.5aq.

Chloride  $C_{10}H_7Br(SO_2Cl)$  [87°]. (Jolin, *Bl.* 28, 516). In its preparation there is also formed  $C_{10}H_7Cl(SO_3Br)$  [116°] (Gessner, *B.* 9, 1504).

Bromide  $C_{10}H_7Br(SO_3Br)$  [115°] (*J.*).

Amide  $C_{10}H_7Br(SO_2NH_2)$  [190°] (*J.*); [195°] (*O.*).

Bromo-naphthalene ( $\alpha$ )-sulphonic acid  $C_{10}H_7Br(SO_3H)$ . [104°]. Formed by brominating naphthalene ( $\alpha$ )-sulphonic acid (*D. a. W.*).  $PBr_3$  gives di-bromo naphthalene [131°].— $KA'$ .

Chloride  $C_{10}H_7Br(SO_2Cl)$  [90°] (*J.*).

Amide  $C_{10}H_7Br(SO_2NH_2)$  [205°] (*J.*).

Bromo-naphthalene ( $\beta$ )-sulphonic acid  $C_{10}H_7Br(SO_3H)$ . [62°]. Formed by brominating naphthalene ( $\beta$ )-sulphonic acid (*D. a. W.*). Crystalline mass, sol. ether (difference from the two preceding acids).— $KA'$ .

Bromo-naphthalene sulphonic acid  $C_{10}H_7Br(SO_3H)$ . Formed in small quantity in preparing its isomeride [139°] by sulphonating ( $\alpha$ )-bromo-naphthalene with  $H_2SO_4$  or  $ClSO_3H$  (Armstrong a. Williamson, *C. J. Proc.* 1, 234).

Chloride  $C_{10}H_7BrSO_2Cl$  [151°].

Di-bromo-naphthalene ( $\beta$ )-sulphonic acid  $C_{10}H_6Br_2(SO_3H)$ . Formed by brominating naphthalene ( $\beta$ )-sulphonic acid (*J.*). Crystalline.  $PBr_3$  gives tri-bromo-naphthalene [87°].

Chloride  $C_{10}H_6Br_2(SO_2Cl)$  [109°].

Amide  $C_{10}H_6Br_2(SO_2NH_2)$  [238°].

Di-bromo-naphthalene sulphonic acid  $C_{10}H_6Br_2(SO_3H)$ . Got by sulphonating di-bromo-naphthalene (Laurent, *A.* 72, 299).— $KA'$ .— $BaA'$ .

**BROMO-NAPHTHALIC ACID v. BROMO-ox-( $\alpha$ )-NAPHTHOQUINONE.**

**BROMO-( $\alpha$ )-NAPHTHOIC ACID**  $C_{11}H_7BrO_2$  i.e.  $C_{10}H_6Br.CO_2H$  [1:4']. [246°] (*Ek.*

strand, *B.* 19, 1135). Produced from its nitrile or by brominating ( $\alpha$ )-naphthoic acid (Hausmann, *B.* 9, 1516). White needles (by sublimation).— $\text{KA}'_2$  1 aq.— $\text{CaA}'_2$  1 aq. S. 1.5 at 20°.— $\text{BaA}'_2$  3 aq. S. 1.7 at 21°.— $\text{AgA}'$ .

*Amide*  $\text{C}_{10}\text{H}_7\text{Br.CONH}_2$ : [211°]; flat needles.

*Nitrile*  $\text{C}_{10}\text{H}_6\text{Br.CN}$ : [147°]. From ( $\alpha$ )-naphthonitrile in  $\text{CS}_2$  and Br.

**Bromo-( $\beta$ )-naphthoic acid**  $\text{C}_{10}\text{H}_7\text{Br.CO.H}$ . [256°]. From ( $\beta$ )-naphthoic acid and Br (II). Needles (by sublimation).— $\text{KA}'_2$  2 aq.— $\text{CaA}'_2$  3 aq. S. .02 at 20°.— $\text{BaA}'_2$  3 aq. S. .023 at 21°.— $\text{AgA}'$ .

*Nitrile*  $\text{C}_{10}\text{H}_6\text{Br.CN}$ : [149°]; flat needles.

**Tri-bromo-( $\beta$ )-naphthoic acid**  $\text{C}_{10}\text{H}_4\text{Br}_3\text{CO.H}$ . [270°]. From ( $\beta$ )-naphthoic acid (1 mol.), Br (3 mols.), and I at 350°. Needles (by sublimation).— $\text{BaA}'_2$  (II).

**Tetra-bromo-( $\alpha$ )-naphthoic acid**  $\text{C}_{10}\text{H}_2\text{Br}_4\text{CO.H}$ . [239°]. From ( $\alpha$ )-naphthoic acid (1 mol.) and Br ( $\frac{1}{2}$  mols.) at 350° (II). (Granules (from alcohol) or needles (by sublimation).— $\text{BaA}'_2$ .

**Tetra-bromo-( $\beta$ )-naphthoic acid**  $\text{C}_{10}\text{H}_2\text{Br}_4\text{CO.H}$ . [260°]. Preparation and properties similar to those of the preceding acid (II).

**BROMO-( $\alpha$ )-NAPHTHOL**. *Ethyl ether*  $\text{C}_{10}\text{H}_7\text{Br(OEt)}$ . [18°]. From ethyl bromo-( $\alpha$ )-naphthol and Br (Marchetti, *C. N.* 40, 87). Prisms, v. sol. ether.

**Bromo-( $\beta$ )-naphthol**  $\text{C}_{10}\text{H}_7\text{Br(OH)}$  [3:2] ? [84°]. Prepared by adding Br in glacial acetic acid slowly to naphthol in glacial acetic acid (A. J. Smith, *C. J.* 35, 789). Needles. Sol. alcohol, ether, light petroleum and benzene. At 130° it begins to decompose, giving off HBr. Oxidised by alkaline  $\text{KMnO}_4$  to phthalic acid.  $\text{PBr}_5$  gives di-bromo-naphthalene [68] and ( $\beta$ )-bromo-naphthalene (Canzoneri, *C. J.* 12, 421).

*Acetyl derivative*  $\text{C}_{10}\text{H}_6\text{Br(OAc)}$ . (215°) at 20 mm. (C).

*Nitroso-derivative*  $\text{C}_{10}\text{H}_7\text{(NO)Br(OH)}$ . [65°]; green needles.

**Di-bromo-( $\alpha$ )-naphthol**  $\text{C}_{10}\text{H}_5\text{Br}_2\text{(OH)}$  [1:3:4]. [106°] (Fittig, *A.* 227, 241). Formed by brominating ( $\alpha$ )-naphthol in  $\text{HOAc}$  (Biedermann, *B.* 6, 1119) and in small quantity from di-bromo-( $\alpha$ )-naphthylamine by the diazo-reaction (Meldola, *C. J.* 45, 161). Long needles (from alcohol). Powerful oxidising agent.

*Reactions*.—1.  $\text{KMnO}_4$  gives phthalic acid.—2. Alcoholic KOH gives tri-oxy-naphthalene.—3. Combines with aniline forming a white crystalline salt. If this is heated for 10 minutes at 200°, and then allowed to cool, crystals of  $\text{C}_{10}\text{H}_7\text{(NPHI)}\langle\text{O}^{\text{Ph}}\rangle_{\text{N}}$  or ( $\beta$ )-naphthoquinone di-anilide (*q. v.*) are got (Meldola, *C. J.* 45, 156).—4. *p*-Toluidine forms the corresponding ( $\beta$ )-naphthoquinone di-toluide (*q. v.*)—5. ( $\beta$ )-naphthylamine forms the corresponding ( $\beta$ )-naphthoquinone di-naphthalide (*q. v.*).

**Tetra-bromo-( $\beta$ )-naphthol**  $\text{C}_{10}\text{H}_2\text{Br}_4\text{OH}$  [156°]. Prepared by adding excess of bromine to ( $\beta$ )-naphthol dissolved in glacial acetic acid (A. J. Smith, *C. J.* 35, 791). White needles (from glacial acetic acid). Sol.  $\text{CS}_2$ , benzene and alkalis. Oxidised by  $\text{KMnO}_4$  and KOH to bromophthalic acid (anhydride [125°]). Hence it is  $\text{C}_{10}\text{H}_2\text{Br}_4\text{(C.H.BrOH)}$ .

**Penta-bromo-( $\alpha$ )-naphthol**  $\text{C}_{10}\text{H}_2\text{Br}_5\text{OH}$  [3:4:1:3:4:1]. [239°]. Formed by bromination

of ( $\alpha$ )-naphthol in presence of  $\text{Al}_2\text{Br}_6$ . Slender felted needles. Sl. sol. benzene, xylene, and cumene, nearly insol. alcohol and ether. Dissolves in alkalis. By dilute  $\text{HNO}_3$  at 100° it is oxidised to tetra-bromo-( $\alpha$ )-naphthoquinone [265°]; at 150° it is oxidised to di-bromo-phthalic acid [206°].— $\text{C}_{10}\text{H}_6\text{Br}_4\text{ONa}$ : long easily soluble needles.— $\text{C}_{10}\text{H}_6\text{Br}_5\text{OK}$ : small colourless needles (Blumlein, *B.* 17, 2485).

**Penta-bromo-( $\beta$ )-naphthol**  $\text{C}_{10}\text{H}_2\text{Br}_5\text{(OH)}$ . [237°]. Formed by bromination of ( $\beta$ )-naphthol in presence of  $\text{Al}_2\text{Br}_6$ . White needles. Insol. alcohol, sl. sol. benzene. It is oxidised by  $\text{HNO}_3$  to tetra-bromo-( $\beta$ )-naphthoquinone; on further oxidation it yields tri-bromo-phthalic acid  $\text{C}_{10}\text{H}_2\text{Br}_3\text{(ONa)}$ : long white silky needles (Flessa, *B.* 17, 1479).

**Bromo-( $\beta$ )-naphthol ( $\alpha$ )-sulphonic acid**

$\text{C}_{10}\text{H}_6\text{Br(OH)SO}_3\text{H}$ . [3:2:1]?

*Salts*.—Formed by adding the calculated quantity of bromine to saturated solutions of the salts of ( $\beta$ )-naphthol ( $\alpha$ )-sulphonic acid (Armstrong a. Graham, *C. J.* 39, 137).— $\text{KA}'$ . S. 4 at 15°. Boiling  $\text{HNO}_3$  forms phthalic acid.— $\text{CaA}'_2$  aq.

### BROMO-( $\alpha$ )-NAPHTHOQUINONE

*Anilide*  $\text{C}_{10}\text{H}_6\text{Br(NH.C}_6\text{H}_5\text{).O}_2$ . [166°]. Formed by the action of aniline on bromo-oxy-( $\alpha$ )-naphthoquinone [197°] in acetic acid solution. Red prisms. Sol. hot alcohol and hot acetic acid. By cold aqueous NaOH it is split up into its constituents (Baltzer, *B.* 14, 1902).

An isomeric *anilide*  $\text{C}_{10}\text{H}_6\text{Br(NPhH).O}_2$  [2:3:4:1] [194°] is formed by boiling di-bromo-( $\alpha$ )-naphthoquinone [218°] with an alcoholic solution of aniline. It is converted by KOH into bromo-oxy-( $\alpha$ )-naphthoquinone [202°] (Miller, *Bl.* [2] 43, 125).

*p*-Bromo-anilide  $\text{C}_{10}\text{H}_6\text{Br(NH.C}_6\text{H}_4\text{Br).O}_2$ . [210°]. Prepared by bromination of ( $\alpha$ )-naphthoquinone-anilide, or by boiling a mixture of *p*-bromo-aniline and bromo-oxy-( $\alpha$ )-naphthoquinone with acetic acid. Red needles. Sol. benzene, sl. sol. alcohol. By alcoholic  $\text{H}_2\text{SO}_4$  it is decomposed into bromo-oxy-( $\alpha$ )-naphthoquinone and *p*-bromo-aniline (Baltzer, *B.* 14, 1901).

**Bromo-( $\beta$ )-naphthoquinone**  $\text{C}_{10}\text{H}_6\langle\text{CO.CO}\rangle_{\text{CH:CHBr}}$ . [178°]. Obtained by bromination of ( $\beta$ )-naphthoquinone in acetic acid. Red needles or prismatic crystals. M. sol. warm alcohol, benzene, and acetic acid. Sublimable. Dissolves in dilute caustic alkalis with a brownish red colour, forming bromo-oxy-( $\alpha$ )-naphthoquinone [196°] (Zincke, *B.* 19, 2495).

**Di-bromo-( $\alpha$ )-naphthoquinone**  $\text{C}_{10}\text{H}_4\text{Br}_2\text{O}_2$ . [151°]. S. (alcohol) 48 at 13°. Formed by the action of Br (7 pts.) and I (2 pts.) on ( $\alpha$ )-naphthol (1 pt.) in presence of water (Diehl a. Merz, *B.* 11, 1065). Yellow needles; may be sublimed. Alkalis from HBr and bromo-oxy-naphthoquinone.

**Di-bromo-naphthoquinone**  $\text{C}_{10}\text{H}_4\text{Br}_2\text{O}_2$ . [171°–173°] [1:4:1:4]? S. (95 p.c. alcohol) 34 at 16°. From di-bromo-naphthalene [82°],  $\text{CrO}_3$ , and glacial acetic acid (Guareschi, *A.* 222, 279). Yellow needles (from alcohol). Insol. water. Cannot be sublimed. Volatile with steam.  $\text{CrO}_3$  does not oxidise it to di-bromophthalide.

**Di-bromo-( $\beta$ )-naphthoquinone**  $C_{10}H_6Br_2O_2$  [1:2:3:4]. [174°]. Obtained by the action of bromine upon bromo-( $\beta$ )-naphthoquinone in hot acetic acid, or better upon ( $\alpha$ )-amido-( $\beta$ )-naphthol or its sulphate. Thick red plates or tables. Sl. sol. alcohol and ether (Zincke, *B.* 19, 2196).

**Di-bromo-naphthoquinone**  $C_{10}H_6Br_2O_2$ . [218°]. From ( $\alpha$ )-naphthoquinone, Br, and I (Miller, *Bl.* [2] 38, 138). Prisms. Converted by KOH into bromo-oxy-naphthoquinone. [200°].

*Anilide* [194°].

**Tetra-bromo-( $\alpha$ )-naphthoquinone**  $C_{10}H_2Br_4O_2$ . [265°]. Yellow plates. Sl. sol. alcohol. Formed by oxidation of penta-bromo-( $\alpha$ )-naphthol with dilute  $HNO_3$ , ft 100°. By further oxidation at 150° it yields di-bromo-phthalic acid [206°] (Blümlein, *B.* 17, 2488).

**Tetra-bromo-( $\alpha$ )-naphthoquinone**  $C_{10}H_2Br_4O_2$  [1:4:2:3:1:4]. [224°]. Formed by oxidising tetra-bromo-naphthalene [173°]. Orange-yellow prisms, v. sol. hot water (Guarreschi, *G.* 16, 149).

**Tetra-bromo-( $\beta$ )-naphthoquinone**  $C_{10}H_2Br_4O_2$ . [164°]. Red granular crystals. Sl. sol. alcohol. Formed by oxidation of penta-bromo-( $\beta$ )-naphthol with dilute  $HNO_3$ . By further oxidation it is converted into tri-bromo-phthalic acid (Flessa, *B.* 17, 1481).

**BROMO-NAPHTHOSTYRIL** *v.* *Inner anhydride of Bromo-amino-naphthoic acid.*

**DI-BROMO-( $\alpha\alpha$ )-DINAPHTHYL**  $C_{20}H_{12}Br_2$ . [215°]. From di-naphthyl and bromine-vapour (Lossen, *A.* 144, 77). Monoclinic prisms; v. sl. sol. alcohol.

**Hexa-bromo-( $\alpha\alpha$ )-dinaphthyl**  $C_{20}H_2Br_6$ . Resin.

**Hepta-bromo-( $\beta\beta$ )-dinaphthyl**  $C_{20}H_2Br_7$ . Amorphous (Smith & Poynting, *C. J.* 27, 851).

**BROMO-NAPHTHYLAMINE**  $C_{10}H_7Br(NH_2)$ . By reduction of bromo-nitro-naphthalene [85°] of Jolin, itself got from ( $\alpha$ )-bromo-naphthalene by nitration. An oil. May be distilled with steam.  $Fe_2Cl_6$  gives a violet colour in its aqueous solution. Reduces  $AgNO_3$  (Guarreschi, *A.* 222, 299). Possibly identical with Rother's (1, 4)-bromo-naphthylamine [94°].

**m-Bromo-( $\alpha$ )-naphthylamine**  $C_{10}H_7Br(NH_2)$  [3:1]. [62°]. From the nitro-compound, zinc-dust, and  $HIOAc$  (Meldola, *C. J.* 47, 509). Needles (from dilute alcohol).

*Acetyl derivative*  $C_{10}H_7Br(NHAc)$  [187°]: needles.

**o-Bromo-( $\beta$ )-naphthylamine**  $C_{10}H_7Br(NH_2)$  [1:2]. [63°]. Got by saponification of the acetyl derivative obtained by bromination of acetyl ( $\beta$ )-naphthylamine [131°]. Small white needles. Volatile with steam. It is a neutral body. Dilute  $HNO_3$  gives phthalic acid (Meldola, *C. J.* 43, 6). When  $NH_2$  is displaced by  $H$  ( $\alpha$ )-bromo-naphthalene results (M.).

*Acetyl derivative*  $C_{10}H_7Br(NHAc)$  [135°]. Needles (Cosiner, *B.* 14, 59).

**Bromo-( $\alpha$ )-naphthylamine**  $C_{10}H_7Br(NH_2)$  [1:1' or 4']. [64°]. From bromo-nitro-naphthalene [122-5°] (Guarreschi, *A.* 222, 297). Volatile with steam. Plates (from boiling water). May be sublimed.  $KMnO_4$  forms *c*-bromo-phthalic acid [165°-172°].— $BHCl$ .

**m-Bromo-( $\beta$ )-naphthylamine**  $C_{10}H_7Br(NH_2)$  [1:3]. [72°]. From Liebermann's bromo-nitro-naphthalene by reduction (Meldola, *C. J.* 47, 509). Converted into (1, 3)-di-bromo-naphthalene by the diazo-reaction.

*Acetyl derivative*  $C_{10}H_7Br(NHAc)$ . [187°]: needles.

**p-Bromo-( $\alpha$ )-naphthylamine**  $C_{10}H_7Br(NH_2)$  [1:4]. [94°]. From its acetyl derivative and KOH (Rother, *B.* 4, 850; Meldola, *B.* 12, 1961). Needles. On oxidation it gives phthalic acid. By diazo-reaction it gives ( $\alpha$ )-bromo-naphthalene. Br gives di-bromo-naphthylamine [119°].

*Acetyl derivative*  $C_{10}H_7Br.NHAc$ . [192°]. Prepared by slowly adding  $HCl$  to a solution of bromine in  $NaOH$  in which is suspended acetyl-( $\alpha$ )-naphthylamine. White needles (Prager, *B.* 18, 2159).

**Di-bromo-( $\alpha$ )-naphthylamine**  $C_{10}H_5Br_2(NH_2)$  [3:2' or 3:1']. [102°]. From its acetyl derivative. Needles; sol. boiling dilute acids. Removal of  $NH_2$  gives di-bromo-naphthalene [74°] (? [1:1']).

*Acetyl derivative*  $C_{10}H_5Br_2(NHAc)$  221°. From acetyl-(3, 1)-bromo-naphthylamine and Br (Meldola, *C. J.* 47, 514).

**Di-bromo-( $\alpha$ )-naphthylamine**  $C_{10}H_5Br_2(NH_2)$  [1:3:1]. [105°]. From its acetyl derivative. Needles. Oxidised by dilute  $HNO_3$  to *c*-bromo-phthalic acid [174°]. Converted into di-bromo-naphthalene [74°] by diazo-reaction.

*Acetyl derivative*  $C_{10}H_5Br_2(NHAc)$ . [222°]. From bromo-naphthylamine [62°] by acetylation and bromination (Meldola, *C. J.* 47, 512; *C. J. Proc.* 1, 173).

**Di-bromo-( $\alpha$ )-naphthylamine**  $C_{10}H_5Br_2(NH_2)$  [1:3:4]. [119°]. From the acetyl derivative by hot aqueous KOH. Needles; does not combine with acids. Oxidation gives phthalic acid; the diazo-reaction gives (1, 3)-di-bromo-naphthalene.

*Acetyl derivative*  $C_{10}H_5Br_2(NHAc)$ . [225°]. Formed by bromination of acetyl-( $\alpha$ )-naphthylamine (Meldola, *B.* 12, 1961).

**Di-bromo-( $\beta$ )-naphthylamine**  $C_{10}H_5Br_2(NH_2)$  [121°]. Long colourless needles. Formed by the action of bromine in acetic acid solution upon ( $\beta$ )-naphthalene-azo-( $\beta$ )-naphthylamine.

*Acetyl derivative*: [208°] (Lawson, *B.* 18, 2424).

**Tetra-bromo-naphthylamine**

*Acetyl derivative*  $C_{10}H_3Br_4NHAc$ . [138°]. Formed by brominating acetyl-(1, 2)-bromo-( $\beta$ )-naphthylamine in acetic acid solution (Meldola, *C. J.* 43, 8). Minute needles (from alcohol). Could not be saponified.

**BROMO-NAPHTHALENE-DIAMINE.**

*Acetyl derivative*  $C_{10}H_3Br(NH_2)(NHAc)$  [2:4:1] [c. 222°]. From bromo-nitro-acetnaphthalide. Is not basic (Meldola, *C. J.* 47, 499).

**Di-bromo-(1:1' or 4')-naphthylene-diamine**  $C_{10}H_4Br_2(NH_2)_2$ . From naphthylene-diamine hydrochloride (from ( $\alpha$ )-di-nitro-naphthalene) and bromine-water (Hollenmann, *Z.* 1865, 556).

**DI-BROMO-( $\alpha$ )-DINAPHTHYLENE-OXIDE**  $C_{20}H_{10}Br_2O$ . [287°]. Light-yellow crystals. Sl. sol. benzene and acetic acid. Prepared by the action of Br on a  $CS_2$  solution of ( $\alpha$ )-dinaphthylene-oxide (Knecht & Unzeitig, *B.* 13, 1725).

**Di-bromo-( $\beta$ )-dinaphthylene-oxide**  $C_{20}H_{10}Br_2O$ . [247°]. Yellow needles. Prepared by the action of bromine on a  $CS_2$  solution of ( $\beta$ )-dinaphthylene-oxide (K. & A. U.).

**DI-BROMO-DI-NAPHTHYL-METHANE**  $C_{20}H_{14}Br_2$ . [193°]. From di-naphthyl-methane and Br (Grabowski, *B.* 7, 1605). Needles (from

alcohol-benzene); not affected by boiling alcoholic KOH.

#### BROMO-NICOTINE v. NICOTINE.

#### BROMO-*o*-NITRO-ACETOPHENONE

$C_6H_4BrNO_2$ , i.e. [2:1]  $C_6H_4(NO_2)CO.CH_2Br$ . [56°]. By bromination of  $C_6H_4(NO_2)CO.Me$  (Gavekoht, A. 221, 327). Needles (from benzoline).

#### Bromo-*m*-nitro-acetophenone

[3:1]  $C_6H_4(NO_2)CO.CH_2Br$ . *m*-Nitro-phenyl bromomethyl ketone. [96°]. Formed by nitrating bromo-acetophenone. Needles (from dilute alcohol); v. sl. sol. ether. Oxidation gives *m*-nitro-benzoic acid (Hunniss, B. 10, 2008).

#### Di-bromo-*o*-nitro-acetophenone

$C_6H_3(NO_2)_2CO.CH_2Br$ . [86°]. Prepared like the above (G.). Attacks the eyes. Prisms (from benzoline).

#### $\omega$ -Di-bromo-*m*-nitro-acetophenone

$C_6H_3(NO_2)_2CO.CH_2Br$ . *m*-Nitro-phenyl di-bromomethyl ketone. [59°]. Formed by careful nitration of  $\omega$ -di-bromo-acetophenone; or by further bromination of  $\omega$  bromo-*m*-nitro-acetophenone. Yellowish tables. V. sol. most solvents (Engler a. Hassenkamp, B. 18, 2240).

#### BROMO-NITRO-*o*-AMIDO-BENZOIC ACID

$C_6H_3Br(NO_2)(NH_2)CO_2H$  [1:22:4:5]. [272°]. Formed by treating nitro-isatoic acid at 100° with bromine dissolved in glacial acetic acid (Dorsch, J. pr. [2] 33, 40). Long yellow needles. Sol. hot water, acetone, alcohol, glacial acetic acid and ether. Insol. chloroform and benzene.

#### Di-bromo-nitro-*o*-amido-benzoic acid

$C_6H_2Br_2(NO_2)(NH_2)CO_2H$ . [c. 203°]. From nitro-isatoic acid and bromine in glacial acetic acid at 100° (D.). Plates. Sol. acetone, alcohol and glacial acetic acid, less sol. benzene, chloroform, and ether, insol. water.

#### Tri-bromo-nitro-*o*-amido-benzoic acid

$C_6HBr_3(NO_2)(NH_2)CO_2H$ . [196°]. From nitro-isatoic acid and bromine (D.). Needles (ppd. by adding water to its solution in acetone). V. sol. acetone, alcohol, ether, glacial acetic acid, chloroform and benzene.

#### (3:5:4:1)-BROMO-NITRO-AMIDO-PHENYL-

ACETIC ACID  $C_6H_3Br(NO_2)(NH_2)CH_2CO_2H$  [3:5:4:1]. [192°]. Prepared by saponification of the acetyl derivative of (3:5:4:1)-bromo-nitro-amido-benzyl cyanide (Gabriel, B. 15, 1994). Long yellow needles. Sol. hot alcohol, ether and acetic acid, sl. sol. cold water, benzene, and chloroform.

#### Nitrile

$C_6H_3Br(NO_2)(NH_2)CH_2CN$  [3:5:4:1]. *Bromo-nitro-amido-benzyl cyanide*. *Acetyl derivative*: [191°]. Formed by nitration of the acetyl derivative of (3:4:1) bromo-amido-phenyl-acetonitrile (Gabriel, B. 15, 1992). Slender yellow needles, sol. alcohol and acetic acid, sl. sol. cold water, v. sl. sol. ether and  $CS_2$ .

#### BROMO-NITRO-ANILINE

$C_6H_4Br(NO_2)(NH_2)$  [1:3:6]. [104°]. Formed by heating  $C_6H_4Br_2(NO_2)$  [59°] with alcoholic  $NH_3$  at 190° (Körner, G. 4, 371). Yellow needles; gives *m*-bromo-nitro-benzene by diazo-reaction. Br forms di-bromo-*p*-nitro-aniline [208°].

*Benzoyl derivative*  $C_6H_4Br(NO_2)(NHBz)$ . [160°]. From benzoyl-*p*-nitro-aniline and Br (Johnson, B. 10, 1709).

*Bromo-nitro-aniline*  $C_6H_4Br(NO_2)(NH_2)$  [1:3:4]. [111°]. S. 014 at 20°; S. (alcohol) 10.4.

*Formation*.—1. From nitro-*p*-di-bromo-benzene and alcoholic  $NH_3$  at 165° (K.; Meyer a. Wurster, A. 171, 59).—2. By nitrating *p*-bromo-aniline in glacial HOAc (Hübner, A. 209, 357). 3. By the action of alcoholic  $NH_3$  on the methyl derivative of (1,3,4)-bromo-nitro-phenol.

*Properties*.—Orange needles; may be sublimed; scarcely basic. Converted by diazo-reaction into *m*-bromo-nitro-benzene [56°].

*Acetyl derivative*  $C_6H_4Br(NO_2)(NHAc)$ . [103°]. Formed by nitrating acetyl-*p*-bromo-aniline (H.). Ammonia and zinc-dust reduce it to  $C_6H_4Br(NHAc)N_2.C_6H_4Br(NHAc)$  [282°] (Matthiessen a. Mixer, Am. 8, 317).

*Benzoyl derivative*  $C_6H_4Br(NO_2)(NHBz)$ . [138°]. Formed by nitrating benzoyl-*p*-bromo-aniline or brominating benzoyl-*o*-nitro-aniline (Meinecke, B. 8, 561; Johnson, B. 10, 1710).

#### Bromo-nitro-aniline

$C_6H_4Br(NO_2)(NH_2)$  [1:2:4]. [132°]. Formed by nitration of *p*-bromaniline dissolved in 10 pts. of  $H_2SO_4$ . Flat plates. V. sol. alcohol, ether, acetic acid, and chloroform, v. sol. water. By further bromination it yields tri-bromo-nitraniline [103°] (Nöling a. Collin, B. 17, 266).

#### Bromo-nitro-aniline

$C_6H_4Br(NO_2)(NH_2)$  [1:4:5]. [151°]. Formed by the action of alcoholic  $NH_3$  upon (1,5,4)-di-bromo-nitro-benzene [62°] or on (1,4,5)-bromo-di-nitro-benzene [56°] (K.; Wurster, B. 6, 1542). Orange needles. Gives by diazo-reaction *p*-bromo-nitro-benzene. Is not basic. Dilute  $HNO_3$  (S.G. 1.38) slowly forms bromo-di-nitro-phenol [81°].

#### Bromo-di-nitro-aniline

$C_6H_3Br(NO_2)_2(NH_2)$  [1:3:5:6]. [151°] (L.); [144°] (K.). Formed by brominating di-nitro-aniline (K.), or by heating di-nitro-methyl-aniline with HOAc and Br (Leymann, B. 15, 1231). Yellow needles. Converted by boiling KOH into bromo-di-nitro-phenol [118°].

*Bromo-di-nitro-aniline*  $C_6H_3Br(NO_2)_2(NH_2)$ . [160°]. From di-bromo-di-nitro-benzene [100°] and alcoholic  $NH_3$  at 100° (Austen, B. 9, 919). Orange scales.

*Bromo-di-nitro-aniline*  $C_6H_3Br(NO_2)_2(NH_2)$ . [178°]. From di-bromo-di-nitro-benzene [117°] and alcoholic  $NH_3$  (K.).

*Bromo-di-nitro-aniline*. *Benzoyl derivative*  $C_6H_3Br(NO_2)_2(NHBz)$  [1:3:5:4]. [221°]. Small needles; formed by nitrating benzoyl bromo-nitro-aniline  $C_6H_3Br(NO_2)(NHBz)$  [1:3:4], or benzoyl di-bromo-aniline (Johnson, B. 10, 1710).

*Bromo-di-nitro-aniline*. *Benzoyl derivative*  $C_6H_3Br(NO_2)_2(NHBz)$ . [196°]. Formed by nitrating benzoyl-*p*-bromo-aniline (Meinecke, B. 8, 561), is probably identical with the preceding.

*Di-bromo-nitro-aniline*  $C_6H_2Br_2(NO_2)(NH_2)$ . [75°]. From di-bromo-di-nitro-benzene [159°] and alcoholic  $NH_3$  at 100° (Austen, B. 9, 622). Red needles.

*Di-bromo-*o*-nitro-aniline*  $C_6H_2Br_2(NO_2)(NH_2)$  [1:3:5:6]. [127°] (Hentschel, J. pr. [2] 34, 426).

*Formation*.—1. By brominating *o*-nitro-aniline or (1,3,4)-bromo-nitro-aniline.—2. By the action of alcoholic  $NH_3$  on (1,3,4,5)-tri-bromo-nitro-benzene or the methyl ether of (1,3,5,6)-di-bromo-nitro-phenol (K.).

*Properties*.—Orange needles.

*Acetyl derivative*  $C_6H_2Br_2(NO_2)(NHAc)$ .

[209°]. From acetyl-di-bromo-aniline by nitration. Needles, v. sol. alkalis (Remmers, *B.* 7, 348).

**Benzoyl derivative**  $C_6H_4Br_2(NO_2)(NHBr)$  [1:3:5:6]? [195°]. Formed by brominating benzoyl-o-nitro-aniline (Johnson, *B.* 10, 1710). Yellow needles.

**Di-bromo-p-nitro-aniline**  $C_6H_3Br_2(NO_2)(NH_2)$  [1:3:5:2]. [207°] (L.); [203°] (K.).

**Formation.**—1. By brominating *p*-nitro-aniline or (1,3,6)-bromo-nitro-aniline. — 2. By the action of alcoholic  $NH_3$  on tri-bromo-nitro-benzene [112°] or the methyl ether of (1,3,5,2)-di-bromo-nitrophenol (K.). — 3. From tri-bromo-aniline in  $HOAc$  by warming with conc.  $HNO_3$  for a short time (Josantsch, *B.* 15, 474).

**Properties.**—Thin yellow needles. Displacement of  $NH_2$  by  $Cl$  gives tri-bromo-benzene [112°].

**Tri-bromo-nitro-aniline**  $C_6HBr_3(NO_2)(NH_2)$  [1:3:5:4:6]. [103°]. From *m*-nitro-aniline and bromine-vapour (K.), or from (1,2,4)-bromo-nitro-aniline and  $Br$  in  $HOAc$  (Nölting a. Collin, *B.* 17, 266). Pale greenish-yellow needles in stellate groups; v. sol. alcohol. Converted by diazo-reaction into (1,3,5,4)-tri-bromo-nitro-benzene.

**Tri-bromo-nitro-aniline**  $C_6HBr_3(NO_2)(NH_2)$  [1:3:5:4:6]? [215°]. From its acetyl derivative (Remmers, *B.* 7, 351). Flat yellow needles; sl. sol. alcohol. This body might be expected to be identical with the preceding.

**Acetyl derivative**  $C_6HBr_3(NO_2)(NHAc)$  [232°]. From acetyl-(1,3,5,6)-tri-bromo-aniline (K.). Needles.

**Di-acetyl derivative**  $C_6HBr_2(NO_2)(NAC)_2$ . Formed by nitrating di-acetyl-tri-bromo-aniline.

**Tri-bromo-nitro-aniline**  $C_6HBr_3(NO_2)(NH_2)$  [1:2:3:5:6]. [161°]. From (1,2,4)-bromo-nitro-aniline [151°] and bromine vapour (K.). Lemon-yellow needles (from alcohol). Converted by diazo-reaction into (1,2,3,5)-tri-bromo-nitro-benzene [112°].

### BROMO-NITRO-ANTHRAQUINONE

$C_{14}H_9(NO_2)(Br)O_2$ . [261° uncor.]. Prepared by nitration of tetra-bromo-anthracene. Whiteneedles. Sublimable. Sol. acetic acid, sl. sol. alcohol, ether, and chloroform. On reduction it gives amido-anthraquinone (Claus a. Hertel, *B.* 14, 980).

#### Bromo-di-nitro-anthraquinone

$C_{14}H_7Br(NO_2)_2O_2$ . [213° uncor.]. Prepared by nitration of tri-bromo-anthracene with a mixture of fuming  $HNO_3$  and fuming  $H_2SO_4$ . Yellow needles. Sol. benzene, chloroform, and acetic acid, m. sol. alcohol and ether (Claus a. Diernfelner, *B.* 14, 1333).

#### Di-bromo-nitro-anthraquinone

$C_{14}H_5Br_2(NO_2)O_2$ . [245° uncor.]. Prepared by nitration of tetra-bromo-anthracene. Sublimable. Fine yellow needles. V. sol. hot acetic acid, less in alcohol and ether. On reduction with sodium-amalgam it gives amido-anthraquinone.

#### Di-bromo-di-nitro-anthraquinone

$C_{14}H_3Br_2(NO_2)_2O_2$ . [239° uncor.]. Prepared by nitration of tetra-bromo-anthracene with a mixture of fuming  $H_2SO_4$  and fuming  $HNO_3$ . Needles. Sol. acetic acid, benzene and chloroform, sl. sol. alcohol and ether (C. a. D.).

#### Tetra-bromo-di-nitro-anthraquinone

$C_{14}HBr_4(NO_2)_2O_2$ . [105°]. Prepared by nitration of dibromo-anthracene-tetrabromide. Sol. alcohol, ether, benzene, and acetic acid. Not

sublimable. On reduction it gives (a)-diamido-anthraquinone (Claus a. Hertel, *B.* 14, 981).

#### *p*-BROMO-o-NITRO-BENZALDOXIM

$C_6H_4N_2O_2Br$  i.e. [2:4:1]  $C_6H_4(NO_2)(Br)(CH:NOH)$  [153°]. Prepared by heating o-nitro-*p*-diazobenzaldoxim with  $HBr$  (Gabriel a. Meyer, *B.* 14, 827). Fine needles. Sol. alcohol, ether, acetic acid, and hot benzene.

#### o-BROMO-NITRO-BENZENE

$C_6H_4Br(NO_2)$  [1:2]. Mol. w. 202. [41°] (F. a. M.); [43°] (K.). (261° i.v.). Formed, together with a much larger quantity of the *p*-isomeride, by nitrating bromo-benzene (Hübner a. Alsborg, *A.* 156, 316; *Z.* [2] 6, 369; Walker a. Zincke, *B.* 5, 114; Fittig a. Mager, *B.* 7, 1179). Yellow needles, more sol. alcohol than the *p*-isomeride.

**Reactions.**—1.  $SnCl_4$  reduces it to o-bromo-aniline. — 2. Alcoholic  $NH_3$  at 190° gives o-nitro-aniline (W. a. Z.). — 3.  $HNO_3$  gives bromo-di-nitro-benzene [72°]. — 4.  $KCN$  and alcohol at 190° gives  $C_6H_4Br.CN$ . — 5. Heating with  $KOH$  gives o-bromo-phenol.

#### *m*-Bromo-nitro-benzene

$C_6H_4Br(NO_2)$  [1:3].

[56°]. (257° i.v.).

**Formation.**—1. From *m*-nitro-aniline by the diazo-reaction (Griess, *T.* 1864 [3] 712). — 2. From (1, 3, 4)-bromo-nitro-aniline (Warster, *B.* 6, 1513; 7, 416). — 3. From nitro-benzene (10 g.),  $FeCl_3$  (1 g.), bromine (13 g.) in sealed tubes for 12 hours at 70° (Scheufelen, *A.* 231, 165). The yield is 80 p.c. of the theoretical. — 4. By the action of a hot solution of cuprous bromide upon *m*-nitro-diazo-benzene sulphate (from *m*-nitraniline) (Sandmeyer, *B.* 18, 1495).

**Properties.**—Yellow trimetric plates. Not attacked by  $KOH$  or alcoholic  $NH_3$ .

#### *p*-Bromo-nitro-benzene

$C_6H_4Br(NO_2)$  [1:4].

[126°]. (256° i.v.).

**Formation.**—1. The chief product obtained by dissolving bromo-benzene in fuming  $HNO_3$  (Couper, *A.* 104, 226). — 2. From *p*-nitro-aniline by the diazo-reaction. — 3. From bromo-nitro-aniline [151°]. — 4. From bromo-benzene *p*-sulphonic acid and  $HNO_3$  (Spiegelberg, *A.* 197, 257). — 5. Formed by the action of precipitated  $Cu_2O$  (1 mol.) upon *p*-bromo-diazo-benzene nitrite (1 mol.) obtained by adding slowly a solution of 15 g. of  $NaNO_2$  in 50 c.c. of water to a mixture of 17 g. of *p*-bromo-aniline, 20 g.  $HNO_3$  (1:4), and 50 c.c. of water. The yield is small (Sandmeyer, *B.* 20, 1496).

**Properties.**—Long white needles, sl. sol.  $HIOEt$ .

**Reactions.**—1. Resembles o-nitro-aniline in reactions 1 and 2. — 2. Alcoholic  $KCN$  at 190° gives *m*-bromo-benzonitrile (Richter, *B.* 4, 462). — 3.  $Br$  at 250° gives *p*-di-, *u*-tri-, and *s*-tetra-bromo-benzenes (A. a. Milliet, *J.* 1876, 370).

**Bromo-di-nitro-benzene**  $C_6H_2Br(NO_2)_2$  [1:3:4]. [59°]. From *m*-bromo-nitro-benzene,  $HNO_3$  and  $H_2SO_4$  (Körner, *J.* 1875, 332). Monoclinic plates (from ether-alcohol). Alcoholic  $NH_3$  at 180° forms  $C_6H_3Br(NO_2)(NH_2)$  [1:4:3] [151°]. Boiling  $NaOH$  aq. (S.G. 1:135) gives  $C_6H_4Br(NO_2)(OH)$  [1:4:3] and a little  $C_6H_3Br(NO_2)(OH)$  [1:3:4] (Laabenheimer, *B.* 11, 1159).

**Bromo-di-nitro-benzene**  $C_6H_3Br(NO_2)_2$  [1:2:4]. [72°]. From bromo-benzene, fuming  $HNO_3$ , and  $H_2SO_4$  in the cold (Kokulé, *A.* 137, 167; Spiegelberg, *A.* 197, 257). Large yellow prisms. Alcoholic  $NH_3$  forms di-nitro-aniline.  $KOH$  aq. forms di-nitro-phenol [114°].  $Sn$  and  $HCl$  gives *m*-

phenylene-diamine (Zincke a. Sintenis, *B* 5, 791). Crystallises with benzene as  $(C_6H_4Br(NO_2))_2 \cdot C_6H_6$  [65°].

**Di-bromo-di-nitro-benzene**  $C_6H_3Br_2(NO_2)_2$ . [87°]. Di-bromo-di-nitro-benzene [158°] is treated with alcoholic  $NH_3$  at 100° and in the resulting  $C_6H_3Br_2(NO_2)_2(NH_2)$  hydrogen is substituted for  $NH_2$  by the diazo-reaction (Austen, *B* 8, 1183). Not affected by alcoholic  $NH_3$ .

**Di-bromo-nitro-benzene**  $C_6H_4Br_2(NO_2)$  [1:2:4]. Mol. w. 281. [59°]. From *o*-di-bromo-benzene and  $HNO_3$  (Riese, *A* 161, 179). Monoclinic tables (Groth a. Bodewig, *B* 7, 1563). May be reduced to di-bromo-aniline [80°].

**Di-bromo-nitro-benzene**  $C_6H_3Br_2(NO_2)$  [1:3:4]. [62°]. Formed by nitrating *m*-di-bromo-benzene (Meyer a. Stücker, *A* 165, 176). Triclinic prisms (by sublimation, G. a. B.); volatile with steam. Converted by alcoholic  $NH_3$  at 190° into (1,4,3)-bromo-nitro-aniline. Reduction gives (1,3,4)-di-bromo-aniline. Alcoholic KCN at 250° gives the nitrile of di-bromo-benzoic acid [209°] (R.).

**Di-bromo-nitro-benzene**  $C_6H_4Br_2(NO_2)$  [1:3:2]. [83°]. Separates from the alcoholic mother-liquors from which the preceding has crystallised. Prisms or laminae. Alcoholic  $NH_3$  at 190° gives nitro-*m*-phenylene-diamine (Körner, *G* 4, 360).

**Di-bromo-nitro-benzene**  $C_6H_3Br_2(NO_2)$  [1:4:5]. [85°]. From *p*-di-nitro-benzene by nitration (Riche a. Bérard, *A* 133, 51). From *m*-bromo-nitro-benzene (14 g.),  $Br_2$  (11.2 g.), and  $FeCl_3$  (4 g.) at 80° for 12 hours (Scheufelen, *A* 231, 169). Yellowish-green tablets (from ether-alcohol). Alcoholic  $NH_3$  at 210° gives (1,3,4)-bromo-nitro-aniline. Sn and HCl gives *p*-di-bromo-aniline [51°]. Alcoholic KCN gives the nitrile of di-bromo-benzoic acid [152°].

**Di-bromo-nitro-benzene**  $C_6H_3Br_2(NO_2)$  [1:3:5]. [105°]. From (1,5,3,6) or (1,5,3,2) di-bromo-nitro-aniline by diazo-reaction (Körner). Prisms or tablets (from ether). May be reduced to di-bromo-aniline [57°].

**Di-bromo-di-nitro-benzene**  $C_6H_2Br_2(NO_2)_2$ . [117°]. Formed by nitrating *m*-di-bromo-benzene (Körner). Greenish-yellow needles, volatile with steam. Heating with KOH aq gives bromo-di-nitro-phenol [92°].

**Di-bromo-di-nitro-benzene**  $C_6H_2Br_2(NO_2)_2$ . [58°]. Formed by nitrating *o*-di-bromo-benzene (Austen, *B* 8, 1182). Prisms (from  $HNO_3$ ). By displacement of Br by  $NH_3$  and H successively it may be converted into bromo-di-nitro-benzene [87°].

**Di-bromo-di-nitro-benzene**  $C_6H_2Br_2(NO_2)_2$ . [120°]. Formed in small quantities in the preparation of the preceding body (A.).

**Di-bromo-di-nitro-benzene**  $C_6H_2Br_2(NO_2)_2$ . [159°]. Formed by nitrating *p*-di-bromo-benzene (Austen, *B* 9, 621). Small needles. Alcoholic  $NH_3$  forms di-bromo-nitro-aniline [75°].

**Di-bromo-di-nitro-benzene**  $C_6H_2Br_2(NO_2)_2$ . [100°]. Formed in preparing the preceding (A.). Alcoholic  $NH_3$  converts it into bromo-di-nitro-aniline [160°].

**Tri-bromo-nitro-benzene**  $C_6H_2Br_3(NO_2)$  [1:3:4:6]. Mol. w. 360. [94°]. Formed by nitrating *u*-tri-bromo-benzene (Mayer, *A* 137, 226). Pale yellowish-green needles (from alcohol). Alcoholic  $NH_3$  gives bromo-nitro-*p*-phenylene-diamine.

### Tri-bromo-nitro-benzene

$C_6H_2Br_3(NO_2)$  [1:2:3:5]. [112°]. From (1,5,3,6)-di-bromo-nitro-aniline [203°] by displacing  $NH_2$  by Br, or from (1,2,3,5,4) tri-bromo-nitro-aniline by displacing  $NH_2$  by H (Körner). Triclinic crystals;  $a:b:c = 1.005:1:1.823$  (La Valle, *G* 10, 1). Reduction gives tri-bromo-aniline. Alcoholic  $NH_3$  gives di-bromo-nitro-aniline [203°].

### Tri-bromo-nitro-benzene

$C_6H_2Br_3(NO_2)$  [1:2:4:6]. [120°]. From (2,4,6,1) di-bromo-nitro-aniline by diazo reaction (Körner). Needles (from  $HNO_3$ ). Alcoholic  $NH_3$  gives the parent di-bromo-nitro-aniline.

### Tri-bromo-nitro-benzene

$C_6H_2Br_3(NO_2)$  [1:3:5:2]. [125°]. (177°) at 11 mm. Prepared by nitration of *s*-tri-bromo-benzene with  $HNO_3$  (1:5) (Wurster a. Beran, *B* 12, 1821; cf. C. L. Jackson, *B* 8, 1172). Formed also by diazo-reaction from (1,3,5,2,4)-tri-bromo-nitro-aniline (Körner, *G* 4, 422). Monoclinic prisms;  $a:b:c = 6518:1:8695$ ;  $\eta = 99.46^\circ$  (Panbianco, *G* 9, 354). Tin and HCl reduce it to ordinary tri-bromo-aniline. Alcoholic  $NH_3$  at 170° gives (1,4,3,5)-bromo-nitro-phenylene-diamine.

### Tri-bromo-nitro-benzene

$C_6H_2Br_3(NO_2)$  [1:3:4:2]. [above 187°]. Formed in small quantity in preparing the isomeride [94°]. Sublimes at 187°.

### Tri-bromo-di-nitro-benzene

$C_6HBr_3(NO_2)_2$  [1:2:1:3:5:2]. [135°]. Formed by nitrating the preceding body (Mayer). Triclinic crystals;  $a:b:c = 455:1:457$  (Panbianco, *G* 9, 355). Alcoholic  $NH_3$  gives bromo-di-nitro-phenylene-diamine.

### Tri-bromo-di-nitro-benzene

$C_6HBr_3(NO_2)_2$  [1:3:4:2:6]. [192°]. Glistening needles. Prepared by nitration of *s*-tri-bromo-benzene with  $HNO_3$  and  $H_2SO_4$  (Wurster a. Beran, *B* 12, 1821).

### Tetra-bromo-nitro-benzene

$C_6HBr_4(NO_2)$  [1:3:4:5:6]. [96° after several fusions]. Slender needles, [60°] (from alcohol). From *u*-tetra-bromo-benzene by nitration. Formed also by heating  $C_6(NO_2)Br_3SO_3H$  with HCl (V. v. Richter, *B* 8, 1427; Langfurth, *A* 191, 202).

### Penta-bromo-nitro-benzene

$C_6Br_5(NO_2)$ . [228°]. From *u*-tetra-bromo-benzene and fuming  $HNO_3$  (R.). Monoclinic prisms (from benzene).

### BROMO-NITRO-BENZENE SULPHONIC

**ACID**  $C_6H_4Br(NO_2)(SO_3H)$  [1:4:2]. [130°-135°]. From bromo-benzene *o*-sulphonic acid and conc.  $HNO_3$  (Ladmann, *A* 186, 315). From *p*-bromo-nitro-benzene and fuming  $F_2SO_4$  (Augustin a. Post, *B* 8, 1559). Flat yellow columns, v. e. sol. water. Reduction gives amido-benzene *m*-sulphonic acid; exchange of  $NO_2$  for Br gives *p*-di-bromo-benzene sulphonic acid.  $-AgA'$ .— $BaA'_2$ , 5 aq. S. (of  $BaA'_2$ ) 5.3 at 16°.— $CaA'_2$ , 4 aq. — $CaA'_2$ , 6 aq. (A. a. P.).— $KA'$ .— $NaA'$ .— $NH_4A'$ .  $PbA'_2$ , 5 aq.  $ZnA'_2$ , 7 aq.

**Chloride**  $C_6H_3Br_2(NO_2)(SO_2Cl)$  [92°]; tables.

**Amide**  $C_6H_3Br_2(NO_2)(SO_2NH_2)$  [205°].

### Bromo-nitro-benzene sulphonic acid

$C_6H_4Br(NO_2)(SO_3H)$  [1:6:2?]. Formed in small quantity in preparing the above by nitrating bromo-benzene *o*-sulphonic acid (B.).— $BaA'_2$ , S. 156 at 8°.— $KA'$ .

**Chloride**  $C_6H_3Br_2(NO_2)(SO_2Cl)$  [97°]; tables.

**Amide**  $C_6H_3Br_2(NO_2)(SO_2NH_2)$ . [215°].

**Bromo-nitro-benzene-sulphonic acid**

$C_6H_4Br(NO_2)(SO_3H)$  [1:3:6]. Formed by heating nitro-diazo-benzene-sulphonic acid (1:3:6) with  $HBr$  (Limpricht, *B.* 18, 2186).

*Chloride*: [75°], large yellow tables.

*Amide*: [166°], small white tables.

**Bromo-nitro-benzene sulphonic acid**

$C_6H_3Br(NO_2)(SO_3H)$  [1:4:3]. Formed by nitrating bromo-benzene *m*-sulphonic acid (Berndsen, *A.* 177, 95; Thomas, *A.* 186, 124). Reduced to amido-benzene *o*-sulphonic acid. Exchange of  $NO_2$  for  $Br$  gives *p*-di-bromo-benzene sulphonic acid. —  $AgA'$  1.1 aq. —  $BaA'$  3 aq. *S.* 2.4 at 7°. —  $CaA'$  6 aq. —  $KA'$  —  $NH_4A'$  —  $PbA'$  3 aq.

*Chloride* •  $C_6H_3Br(NO_2)(SO_3Cl)$ . [83°].

*Amide*  $C_6H_3Br(NO_2)(SO_2NH_2)$ . [170°].

**Bromo-nitro-benzene sulphonic acid**

$C_6H_3Br(NO_2)(SO_3H)$  [1:2:4]. Formed by nitrating bromo-benzene *p*-sulphonic acid (Goslich, *A.* 180, 93; Limpricht, *B.* 8, 456). Formed also by sulphonating *o*-bromo-nitro-benzene (*A. a. P.*; Andrews, *B.* 13, 2127). Reduction by  $H$  at 120° gives amido-benzene *m*-sulphonic acid. —  $BaA'$  aq. *S.* (of  $BaA'_2$ ) 1.71 at 15° (*A.*). —  $BaA'_2$  1 aq. *S.* (of  $BaA'_2$ ) 1.46 at 9° (*G.*). —  $CaA'_2$  2 aq. (*A. a. P.*). —  $CaA'_2$  2 aq. *S.* (of  $CaA'_2$ ) 4.71 at 9° (*G.*). —  $CaA'_2$  9 aq. —  $KA'$  *S.* 1.02 at 9° (*G.*).  $NH_4A'$  *S.* 5.96 at 9°. —  $PbA'_2$  2 aq. —  $ZnA'_2$  2 aq.

*Chloride*  $C_6H_3Br(NO_2)(SO_2Cl)$ . [10°–50°] (*A.*). [57°] (*G.*).

*Amide*  $C_6H_3Br(NO_2)(SO_2NH_2)$ : [177°]; plates.

**Bromo-nitro-benzene di-sulphonic acid**

$C_6H_3Br(NO_2)(SO_3H)_2$ . From nitro-benzene *m*-sulphonic acid and di-nitro-benzene di-sulphonic acid and amido-nitro-benzene di-sulphonic acid (Limpricht, *B.* 8, 289). Trimetric tables (containing aq.).

**Di-bromo-nitro-benzene sulphonic acid**

$C_6H_2Br_2(NO_2)(SO_3H)$  [1:2:4:6]. From *o*-di-bromo-benzene sulphonic acid and fuming  $HNO_3$  (Goslich, *A.* 186, 152). Reduction gives di-bromo-aniline sulphonic acid. —  $BaA'_2$  3 aq. *S.* .9 at 7°. —  $CaA'_2$  4 aq. —  $CaA'_2$  6 aq. —  $KA'$  —  $NH_4A'$  —  $PbA'_2$  3 aq. *S.* .8 at 11°.

*Chloride*  $C_6H_2Br_2(NO_2)SO_3Cl$ . [99°].

*Amide*  $C_6H_2Br_2(NO_2)(SO_2NH_2)$ . [211°].

**Di-bromo-nitro-benzene sulphonic acid**

$C_6H_2Br_2(NO_2)(SO_3H)$  [1:4:3:5]. From (1,4,5)-di-bromo-benzene sulphonic acid and  $HNO_3$  (Borns, *A.* 187, 358; Ilübner u. Williams, *A.* 167, 121). Hygroscopic prisms which blacken at 100°. —  $BaA'_2$  aq. —  $BaA'_2$  1 aq. —  $BaA'_2$  2 aq. —  $BaA'_2$  6 aq. —  $BaA'_2$  9 aq. —  $CaA'_2$  3 aq. —  $CaA'_2$  aq. —  $KA'$  aq. —  $KA'$  2 aq. —  $NH_4A'$  aq. —  $PbA'_2$  2 aq. —  $PbA'_2$  3 aq. *S.* 10.3 at 10°.

*Chloride*  $C_6H_2Br_2(NO_2)(SO_3Cl)$ . Oil (?).

*Amide*  $C_6H_2Br_2(NO_2)(SO_2NH_2)$ . [178°].

**Di-bromo-nitro-benzene sulphonic acid**

$C_6H_2Br_2(NO_2)(SO_3H)$  [1:3:4:5]. From *s*-di-bromo-benzene sulphonic acid and  $HNO_3$  (Lenz, *A.* 181, 32). Tablets (containing aq.); not hygroscopic. By exchanging  $NO_2$  for  $Br$  it is converted into (1,3,4,5)-tri-bromo-benzene sulphonic acid. —  $BaA'_2$  1 aq. *S.* .73 at 20°. —  $BaA'_2$  4 aq. —  $CaA'_2$  3 aq. —  $KA'$  aq. *S.* 1.09 at 20°. —  $NH_4A'$  —  $PbA'_2$  5 aq. *S.* .120 at 20°.

*Chloride*  $C_6H_2Br_2(NO_2)(SO_3Cl)$ . [121°].

*Amide*  $C_6H_2Br_2(NO_2)(SO_2NH_2)$ . Blackens at 300°.

**Di-bromo-nitro-benzene sulphonic acid**

$C_6H_2Br_2(NO_2)(SO_3H)$  [1:3:4:6] [above 200°]. Formed by nitrating  $C_6H_2Br_2SO_3H$  [1:3:4] (Bässmann, *A.* 191, 235). Deliquescent needles or prisms (containing aq.). —  $KA'$  *S.* 1.4 at 21.5°. —  $BaA'_2$  aq. *S.* (of  $BaA'_2$ ) 1.06 at 24°. —  $CaA'_2$  6 aq. —  $PbA'_2$  4 aq.

*Chloride*  $C_6H_2Br_2(NO_2)BrSO_3Cl$ . [115.5°].

*Amide*  $C_6H_2Br_2(NO_2)BrSO_2NH_2$ . Minute tablets. Not melted at 210°.

**Tri-bromo-nitro-benzene sulphonic acid**

$C_6HBr_3(NO_2)SO_3H$  [1:3:5:2:6]. [*c.* 100°]. Formed by nitrating  $C_6H_2Br_2SO_3H$  (Langfurth, *A.* 191, 196; Reinke, *A.* 186, 282; Bässmann, *A.* 191, 216). Hygroscopic, monoclinic prisms. Conc.  $HCl$  at 180° gives  $H_2SO_4$  and  $C_6H_2Br_3(NO_2)$  [125°]. —  $KA'$  *S.* .76 at 5° (*B.*). 1.33 at 11° (*L.*). —  $BaA'_2$  aq. *S.* (of  $BaA'_2$ ) .207 at 1.5° (*B.*). .331 at 15° (*L.*). —  $BaA'_2$  1 aq. —  $CaA'_2$  2 aq. —  $PbA'_2$  9 aq. *S.* (of  $PbA'_2$ ) .63 at 7° (*B.*). .93 at 10° (*L.*). —  $PbA'_2$  1 aq. —  $PbA'_2$  .PbO 7 aq. —  $PbA'_2$  .PbO 6 aq. —  $NH_4A'$ .

*Chloride*  $C_6HBr_3(NO_2)SO_3Cl$ . [145°].

*Amide*  $C_6HBr_3(NO_2)SO_2NH_2$ .

**Tri-bromo-nitro-benzene sulphonic acid**

$C_6HBr_3(NO_2)(SO_3H)$  [1:2:3:4:5]. From (1,2,3,5)-tri-bromo-benzene sulphonic acid by nitration (Limpricht a. Lenz, *B.* 8, 1072, 1432; *A.* 181, 41). Lamine. —  $BaA'_2$  aq. *S.* .074 at 18°. —  $CaA'_2$  3 aq. *S.* 1.05 at 20°. —  $KA'$  aq. *S.* .16 at 18°. —  $NH_4A'$  aq. —  $PbA'_2$  aq. *S.* .14 at 20°.

*Chloride*  $C_6HBr_3(NO_2)(SO_3Cl)$ . [116°].

*Amide*  $C_6HBr_3(NO_2)(SO_2NH_2)$ . [202°].

**Tri-bromo-nitro-benzene sulphonic acid**

$C_6HBr_3(NO_2)(SO_3H)$  [1:3:4:2:6]. [125°] or, anhydrous, [141°]. From (1,2,4,5)-tri-bromo-benzene sulphonic acid and  $HNO_3$  (Spiegelberg, *A.* 197, 284) columns (containing 3 aq.). —  $AgA'$  aq. *S.* (of  $AgA'$ ) .45 at 7°. —  $BaA'_2$  3 aq. *S.* (of  $BaA'_2$ ) .669 at 9°. —  $CaA'_2$  4 aq. *S.* (of  $CaA'_2$ ) 1.95 at 8°. —  $KA'$  *S.* 1.19 at 8°. —  $NH_4A'$  *S.* 1.68 at 6.5°. —  $PbA'_2$  6 aq. *S.* (of  $PbA'_2$ ) .853 at 7°.

*Chloride*  $C_6HBr_3(NO_2)(SO_3Cl)$ . [143°].

*Amide*  $C_6HBr_3(NO_2)(SO_2NH_2)$ . Blackens at 250°.

**Tri-bromo-di-nitro-benzene sulphonic acid**

$C_6Br_3(NO_2)_2SO_3H$  [1:3:5:2:4:6]. [216°]. From  $C_6H_2Br_2SO_3H$  and conc.  $HNO_3$  at 100° (Bässmann, *A.* 191, 239). Colourless columns (containing 3 aq.). Not hygroscopic, but *v. sol.* water, *sol.* alcohol. — With water at 230° it gives  $C_6HBr_3(NO_2)_2$  and  $H_2SO_4$ . Reduced by  $Sn$  and  $HCl$  to  $C_6H_2Br_3(NH_2)_2SO_3H$ . —  $NH_4A'$  aq. —  $KA'$  aq. *S.* (of  $KA'$ ) .48 at 24°. —  $BaA'_2$  9 aq. *S.* (of  $BaA'_2$ ) .83 at 21°. —  $CaA'_2$  7 aq. —  $PbA'_2$  9 aq. *S.* (of  $PbA'_2$ ) 1.02 at 19.5°.

*Chloride*  $C_6Br_3(NO_2)_2SO_3Cl$ . [203°].

*Amide*  $C_6Br_3(NO_2)_2SO_2NH_2$ . [260°].

**Tetra-bromo-nitro-benzene sulphonic acid**

$C_6Br_4(NO_2)SO_3H$  [1:2:3:5:4:6]. Got by nitrating  $C_6HBr_3SO_3H$ . Crusts of needles (containing 4 aq.). *V. sol.* alcohol and water (Beckurts, *A.* 181, 220; Langfurth, *A.* 191, 202). With conc.  $HCl$  at 200° it gives  $C_6HBr_4(NO_2)$  and  $H_2SO_4$ . —  $KA'$  1 aq. *S.* (of  $KA'$ ) .57 at 10.5°. —  $BaA'_2$  9 aq. *S.* (of  $BaA'_2$ ) .36 at 11° (*B.*). .100 at 14.5° (*L.*). —  $NH_4A'$  aq. *S.* (of  $NH_4A'$ ) 1.01 at 11°. —  $CaA'_2$  8 aq. *S.* (of  $CaA'_2$ ) .16 at 6°. —  $PbA'_2$  9 aq. *S.* (of  $PbA'_2$ ) .06 at 6°.

*Chloride*  $C_6Br_4(NO_2)SO_3Cl$ : [147.5°]; tablets.

*Amide*: crystalline powder.

**Tetra-bromo-nitro-benzene sulphonic acid**  $C_6Br_4(NO_2)SO_3H$  [1:2:3:4:5:6]. [173°]. From *o*-tetra-bromo-benzene sulphonic acid and  $HNO_3$  (Spiegelberg, A. 197, 297). Slender needles (containing aq.).— $BaA'$ , 4aq. S. (of  $BaA'$ ) 2.2 at 12°.— $BaA'$ , 9aq.— $CaA'$ , aq. S. (of  $CaA'$ ) 2.8 at 13°.— $KA'$ , aq. S. (of  $KA'$ ) 1.7 at 11°.— $NH_4A'$ . S. 4.6 at 11°.— $PbA'$ , 2aq. S. 0.12 at 11°.

**Chloride**  $C_6Br_4(NO_2)(SO_2Cl)$  [173°]; prisms. **Amide**  $C_6Br_4(NO_2)(SO_2NH_2)$ . Blackens at 200°.

#### BROMO-NITRO-BENZOIC ACID

$C_6H_4Br(NO_2)CO_2H$  [1:4:3]. [111°]. Formed, together with the isomeride [250°] by nitrating *m*-bromo-benzoic acid (Hübner, A. Ohly, Z. [2] 1, 547; 2, 241; A. 143, 230; 222, 102). Monoclinic prisms.— $NaA'$ , 3aq.— $NaA'$ , 2½aq.— $KA'$ , 2aq.— $BaA'$ , 4aq.— $CaA'$ , 2aq.— $MgA'$ , 4aq.— $PbA'$ — $CuA'$ — $AgA'$ .

**Ethyl ether EtA'**: [55°]; monoclinic prisms. **Bromo-nitro-benzoic acid**  $C_6H_4Br(NO_2)CO_2H$  [1:3:5]. [161°]. S. 0.57 at 11°. Formed from  $C_6H_4(NH_2)(NO_2)CO_2H$ , glacial acetic acid,  $HBr$  (S.G. 1.49), and nitrous acid gas (Hesemann, A. Köhler, A. 222, 166). Long needles (from water, benzene, ether, or  $CS_2$ ), whetstone-shaped crystals (from glacial acetic acid) or thin six-sided plates (from alcohol).— $KA'$ , ½aq.— $BaA'$ , 5½aq.— $CaA'$ , aq.— $MgA'$ , aq.— $ZnA'$ , 4½aq.— $CdA'$ , 4½aq.— $SrA'$ — $AgA'$ — $PbA'$ .

**Bromo-nitro-benzoic acid**  $C_6H_4Br(NO_2)CO_2H$  [1:3:6]. [164°]. Formed by oxidation of  $C_6H_4Br(NO_2)Me$  by dilute  $HNO_3$  (Scheufelen, A. 231, 173). V. sol. ether and dilute alcohol. Sl. sol. water. Reduced by  $Sn$  and  $HCl$  to *m*-bromo-aniline,  $CO_2$  going off.— $AgA'$ .

**Bromo-nitro-benzoic acid**  $C_6H_4Br(NO_2)(CO_2H)$  [1:4:6]. [180°]. From  $C_6H_4MeBr(NO_2)$  [1:2:5] and dilute  $HNO_3$  (Scheufelen, A. 231, 181) or by nitrating *o*-bromo-benzoic acid (Burghard, B. 8, 560). Almost insol. cold water, sl. sol. hot water, v. sol. ether and dilute alcohol. Alcoholic  $NH_3$  at 130° gives *p*-nitro-aniline and (1, 4, 6)-amido-nitro-benzoic acid.— $BaA'$ , 5½aq.

**Ethyl ether EtA'**: [66°]; needles.

#### Bromo-nitro-benzoic acid

$C_6H_4Br(NO_2)CO_2H$  [1:2:4]. [199°]. Formed by nitration of *p*-bromo-benzoic acid [218] (Hübner, A. 143, 218; Ravcill, A. 222, 177) and by oxidation of the corresponding bromo-nitro-toluene (Scheufelen, A. 231, 183). Long needles (from water) or plates (from dilute alcohol); v. sol. ether, sl. sol. water. Reduction gives *m*-amido-benzoic acid.

**Salts**.— $AgA'$ .— $BaA'$ , 4aq.— $MgA'$ , 6aq.

**Ethyl ether EtA'**: [74°]; prisms.

#### Bromo-nitro-benzoic acid

$C_6H_4Br(NO_2)CO_2H$  [1:2:3]. [250°]. From *m*-bromo-benzoic acid by nitration. Separated from its isomeride [141°] by being less soluble in water (Hübner, A. 143, 234; A. 222, 101). Monoclinic octahedra (from ether).— $NaA'$ , aq.— $BaA'$ , 4aq.— $MgA'$ , 6aq.

**Ethyl ether EtA'**: [80°]; prisms.

#### Di-bromo-nitro-benzoic acid

$C_6H_2Br_2(NO_2)CO_2H$  [3:4:2or6:1]. [162°]. From di-bromo-benzoic acid [230°] by nitration (E. F. Smith, A. 222, 188). Colourless needles; reduction gives anthranilic acid.

**Salts**.— $PbA'$ — $NaA'$ , 3aq.— $KA'$ .— $BaA'$ , 4aq.— $CaA'$ , 3½aq.— $MgA'$ .

#### Di-bromo-nitro-benzoic acid

$C_6H_2Br_2(NO_2)CO_2H$ . [162°]. Formed by nitrating the di-bromo-benzoic acid [223°-227°] obtained by brominating benzoic acid (Angerstein, A. 158, 13). Needles (from water). Reduction gives di-bromo-amido-benzoic acid [196°] and then anthranilic acid.— $NaA'$ , 3aq.— $BaA'$ , 2aq. This acid is perhaps identical with the preceding.

#### Di-bromo-nitro-benzoic acid

$C_6H_2Br_2(NO_2)CO_2H$  [3:5:2:1]. [233°]. Formed by nitration of  $C_6H_4Br_2CO_2H$  (Hesemann, A. Köhler, A. 222, 173). Long colourless needles; may be sublimed.— $BaA'$ , ½aq.— $CaA'$ — $AgA'$ .— $KA'$ .

#### BROMO-NITRO-*o*-BENZYL-PHENOL

$C_6H_4BrNO_2$  [105°-110°]. From potassium nitro-*o*-benzyl-phenol sulphonic acid and  $Br$  (Rennie, C. J. 49, 410). Yellow scales (from alcohol).— $KA'$ .

#### Bromo-nitro-*p*-benzyl-phenol

$Ph.CH_2.C_6H_4Br(NO_2)OH$  [1:3:5:4]. [65°].

**Formation**.—1. From potassium bromo-benzyl-phenol sulphate and dilute  $HNO_3$  (1:1) (Rennie, C. J. 41, 223).—2. From potassium nitro-benzyl-phenol sulphate,  $C_2H_5O_2$ , and  $Br$ .—3. From nitro-benzyl-phenol,  $C_2H_5O_2$ , and  $Br$ .—4. From benzyl-phenol by first brominating and then nitrating.

**Properties**.—Crystalline scales (from alcohol).— $KA'$ . Red scales.  $HNO_3$  oxidises it to bromo-di-nitro-phenol,  $C_6H_3Br(NO_2)_2OH$  [1:2:3:5] [118°].

#### BROMO-NITRO-BUTANE $C_4H_8BrNO_2$ *i.e.*

$C_4H_7.CHBr(NO_2)$ . (181° cor.). From nitro-butane, potash, and  $Br$  (Züblin, B. 10, 2085). The three following compounds are prepared in a similar way (Z.).

**Di-bromo-nitro-butane**  $C_4H_7.CBr_2(NO_2)$ . (204° cor.).

**Bromo-di-nitro-butane**  $C_4H_7.CBr(NO_2)_2$ . Not volatile.

#### Bromo-di-nitro-iso-butane

$(CH_3)_2CH.CBr(NO_2)_2$ . [38°]. Solid resembling camphor. Volatile with steam. Readily decomposed by alkalis forming dinitro-isobutane.

#### BROMO-*m*-NITRO-CINNAMIC ACID

$[3:1]C_6H_4(NO_2).C_6H_4Br.CO_2H$ . [212°]. Formed by heating the dibromide of *m*-nitro-benzylidene-malonie acid (Stuart, C. J. 49, 361).

#### Bromo-*p*-nitro-cinnamic acid

$[4:1]C_6H_4(NO_2).C_6H_4Br.CO_2H$ . [146°]. V. sol. alcohol, ether, chloroform. Sl. sol. hot  $CS_2$ . More sol. in cold water than its isomeride [265°].

**Salts**.— $BaA'$ . Boiled with water gives nitro-phenyl-acetylene,  $CO_2$  and  $BaA'$ .

**Ethyl ether EtA'**: [63°]. Prisms. From  $C_6H_4(NO_2).CHBr.CHBr.CO_2Et$  and alcoholic  $KOH$  (C. L. Müller, A. 212, 131).

#### Bromo-*p*-nitro-cinnamic acid

$[4:1]C_6H_4(NO_2).C_6H_4Br.CO_2H$ . [205°]. Slender silky needles (from water). Sl. sol. cold water, insol. cold  $CS_2$ . V. sol. alcohol, ether, chloroform, or benzoline.

**Salt**.— $BaA'$ . Decomposed by boiling into nitro-phenyl-acetylene,  $CO_2$ , and  $BaA'$ .

**Ethyl ether EtA'**: [93°]. Needles. From di-*exo*-bromo-*p*-nitro-phenyl-propionic ether by alcoholic  $KOH$  (C. L. Müller, A. 212, 131).

#### Di-bromo-*p*-nitro-cinnamic acid

$[4:1]C_6H_4(NO_2)_2.CBr_2.CO_2H$ . [c.180°]. From *p*-nitro-phenyl-propionic acid and  $Br$  (Drewson, A. 212, 157).

**Ethyl ether EtA.** [86°]. V. sol. benzene, chloroform or glacial HOAc, sl. sol. benzoline.

**BROMO-NITRO-CINNAMIC ALDEHYDE**

$C_9H_7(NO_2)CH:CHBr.CO.HO$ . [97°]. Long yellowish needles. Formed together with the isomeride [136°] by nitration of  $\alpha$ -bromo-cinnamic aldehyde.

**Phenyl-hydrazide.** [131°]. Large yellow plates (Zincke a. Hagen, B. 17, 1816).

**Bromo-nitro-cinnamic aldehyde**

$C_9H_7(NO_2)CH:CHBr.CO.HO$ . [136°]. Yellowish needles. Formed as above.

**Phenyl-hydrazide.** [151°]; red crystalline solid, sl. sol. alcohol (Z. a. H.).

**DI-BROMO-NITRO-*o*-CRESOL**

$C_6H_4(CH_3)(NO_2)(Br)_2(OH)$  [1:4:2] [92°]. Formed by bromination of nitro-*o*-cresol  $C_6H_4(CH_3)(NO_2)(OH)$  [1:4:2]. Yellowish needles. V. sol. alcohol and ether, nearly insol. water (Nölting a. Collin, B. 17, 270).

**Di-bromo-nitro-*p*-cresol**

$C_6H_4Me(NO_2)(OH)Br_2$  [1:2:4:2:2]. [83°]. From aqueous nitro-cresol, [78°], and bromine-water. Long yellow needles (from alcohol). Insol. cold water, v. sl. sol. hot water, v. sol. alcohol or ether (E. Knecht, A. 215, 89; B. 15, 1071).

**Salts.** —  $C_6H_4Me(NO_2)(ONa)Br_2.2.aq.$  Red needles (from alcohol). —  $C_6H_4Me(NO_2)(OK)Br_2.aq.$

**DI-BROMO-NITRO-CUMENE**

$C_{11}H_{13}CHBr.CBr(NO_2).CH_3$ . **Di-bromo-nitro-phenyl-propylene.** [77°–78°5']. From Ph.CH<sub>2</sub>.C(NO<sub>2</sub>).CH<sub>3</sub> and Br (Priebs, A. 225, 362). Colourless prisms (from light petroleum). Not decomposed even by hot aqueous NaOH, thus differing markedly from the corresponding di-bromo-nitro-ethyl-benzene.

**Bromo-nitro- $\psi$ -cumene**

$C_9H_7Me.Br(NO_2)$  [1:2:4:3:2]. [192°]. Formed by nitration of bromo-pseudo-cumene [73°] by fuming HNO<sub>3</sub>. Needles. Sol. benzene, sl. sol. alcohol (Kelbe a. Pathe, B. 19, 1548).

**Bromo-di-nitro- $\psi$ -cumene**

$C_9H_7Me_2.Br(NO_2)_2$  [1:2:4:3:5:6]. [181°]. Formed by nitration of bromo-pseudo-cumene [1:2:4:3]. Long yellowish needles. Sl. sol. hot alcohol, nearly insol. cold (Kelbe a. Pathe, B. 19, 1551).

**Bromo-di-nitro- $\psi$ -cumene**

$C_9H_7Me_2.Br(NO_2)_2$  [1:2:4:3:5:6]. [214°]. Formed by nitration of bromo-pseudo-cumene [73°] with fuming HNO<sub>3</sub> and conc. H<sub>2</sub>SO<sub>4</sub>. Microscopic tables. Sol. benzene, sl. sol. hot alcohol, nearly insol. cold alcohol (Fitting, A. 147, 14; Kelbe a. Pathe, B. 19, 1548).

**BROMO-NITRO-*iso*-CUMENOL**  $C_9H_9.BrNO_2$ , i.e.  $C_9H_7(C_2H_5)Br(NO_2)(OH)$  [1:5:3:2]. **Bromo-nitro-isopropyl-phenol.** [33°]. From bromo-isopropyl-phenol and HNO<sub>3</sub> (Fileti, G. 16, 123). Pale yellow needles (from dilute HOAc).

**Bromo-nitro-*iso*-cumenol**

$C_9H_9.Pr.Br(NO_2)(OH)$  [1:3:5:2]. [88°]. From nitro-isopropyl phenol and Br (F.). Nacreous tables (from dilute alcohol); volatile with steam.

**BROMO-NITRO-CUMYL-PROPIONIC ACID**

$C_{12}H_{15}.BrNO_2$ , i.e.  $C_6H_5(C_2H_5)(NO_2).CHBr.CH_2.CO_2H$ . [127°]. From *o*-nitro-*iso*-propyl-cinnamic acid and HBr (Einhorn a. Hess, B. 17, 2020).

**Di-bromo-nitro-cumyl-propionic acid**

$C_6H_5(C_2H_5)(NO_2).CHBr.CHBr.CO_2H$ . [171°]. From *o*-nitro-*iso*-propyl-cinnamic acid and Br (Widman, B. 19, 260).

**Di-bromo-nitro-cumyl-propionic acid.** [184°]. From *m*-nitro-*iso*-propyl-cinnamic acid and Br (Widman, B. 19, 418).

**BROMO-NITRO-CYME**  $C_{10}H_{12}.BrNO_2$ , i.e.  $C_6H_4Me(C_2H_5)Br(NO_2)$  [1:4:3:2]. Formed by nitrating the bromo-cymene derived from thymol (Mazzara, G. 16, 193). Oil, volatile with steam.

**Bromo-di-nitro-cymene**

$C_6H_4MePr.Br(NO_2)_2$  [1:4:2:2:2:2]. [98°]. Formed by nitrating bromo-cymene (229°). Monoclinic prisms (Gerichten, B. 11, 1092). May be identical with the following.

**Bromo-di-nitro-cymene**

$C_6H_4MePr.Br(NO_2)_2$  [1:4:3:2:2]. [94°]. Formed by nitrating the bromo-cymene derived from thymol (M.). Slender yellow needles.

**Bromo-nitro-isocymene**

$C_6H_4(C_2H_5)(CH_3)Br(NO_2)$  [4:2:1:2]. [121°]. Long red needles. Prepared by nitration of (1:2:1)-bromo-isocymene (Kelbe, B. 15, 40).

**Bromo-nitro-*m*-isocymene (?)**  $C_{10}H_{12}(NO_2)Br$ . [83°]. From di-bromo-*m*-isocymene by nitration (Kelbe a. Czarnomski, A. 235, 281).

**Bromo-di-nitro-isocymene**

$C_6H_4(C_2H_5)(CH_3)(NO_2)_2.Br$ . [55°]. Short thick needles. Prepared by nitration of ( $\beta$ )-bromo-isocymene (Kelbe, B. 15, 42).

**BROMO-NITRO-ETHANE**  $C_2H_5.BrNO_2$ , i.e.  $CH_3.CHBr(NO_2)$ . [147°]. Formed by dissolving nitro-ethane (*q.v.*) in aqueous caustic potash and adding bromine:  $CH_3.CHK(NO_2) + Br_2 = CH_3.CHBr(NO_2) + KBr$  (Meyer a. Wurster, B. 6, 94; Tscherniak, B. 7, 916; A. 180, 126).—Pungent oil. Forms unstable salts.

**Bromo-di-nitro-ethane**  $CH_3.CBr(NO_2)_2$ . From Br and potassium dinitroethane (Ter Meer, A. 131, 15).—Oil, volatile with steam; decomposed by K<sub>2</sub>CO<sub>3</sub> which forms  $CH_3.CK(NO_2)_2$ .

**Di-bromo-tetra-nitro-ethane**

$CBr(NO_2)_2.CBr(NO_2)_2$ . From ethylene bromide and fuming HNO<sub>3</sub>, or from  $C(NO_2)_4$  and Br. Unstable liquid; forms with potash a compound  $C_2Br_2(NO_2)_4.2KOH$ , m. sol. hot water, which explodes at about 180°. Ammonium sulphide converts it into  $C_2K_2(NO_2)_4$ . SO<sub>2</sub> forms NH<sub>4</sub>, HBr, and HCN. Aqueous K<sub>2</sub>SO<sub>4</sub> forms yellow crystals  $C_2(NO_2)_4.K_2K_2SO_4$  (Villiers, C. R. 94, 1122; 98, 431).

**Di-bromo-nitro-ethane**  $CH_3.CBr_2(NO_2)$ . [165°]. Formed by adding potash to a mixture of nitro-ethane (*q.v.*) and the calculated quantity of bromine (V. Meyer, B. 7, 1313). Indifferent oil, insol. KHO.

**BROMO-NITRO-ETHENYL-NAPHTHYLENE-DIAMINE**

$C_{10}H_7.Br(NO_2) < \begin{smallmatrix} N \\ \backslash \end{smallmatrix} \begin{smallmatrix} / \\ NH \end{smallmatrix} > C_6H_5$ , [4:2:2]. [242°].

Formed by nitration of ethenyl-(4:2:1)-bromonaphthylene-diamine (Prager, B. 18, 2162). Yellow needles sl. sol. alcohol, v. sol. HNO<sub>3</sub>Aq.

**$\omega$ -DI-BROMO-*o*-NITRO-ETHYL-BENZENE**

$C_8H_7.Br_2.NO_2$ , i.e. [2:1]  $C_6H_4(NO_2).CHBr.CH_2Br$ . ***o*-nitro-styrene dibromide.** [52°]. From *o*-nitro-styrene and Br (Einhorn, B. 16, 2213).

**$\omega$ -Di-bromo-*m*-nitro-ethyl-benzene** [3:1]  $C_6H_4(NO_2).CHBr.CH_2Br$ . [79°]. From *m*-nitro-styrene and Br (Praisnitz, B. 17, 598).

**$\omega$ -Di-bromo-*p*-nitro-ethyl-benzene**

[4:1]  $C_6H_4(NO_2).CHBr.CH_2Br$ . [73°]. From *p*-nitro-styrene and Br (Basler, B. 16, 3006).

**$\omega$ -Di-bromo- $\omega$ -nitro-ethyl-benzene**  
 $C_6H_4.CHBBr.CHBBr.NO_2$ . [86°]. From  $\omega$ -nitro-phenyl-ethylene and Br (Erdmann, *B.* 17, 414). Also from  $\omega$ -nitro-ethyl-benzene and Br (Priebs, *A.* 225, 341). Monoclinic crystals,  $a:b:c = 1.257:1.1896; L = 83^\circ 54'$ . Cold aqueous NaOH gives bromo-nitro-styrene.

**$\omega$ -Di-bromo- $\omega$ -di-nitro-ethyl-benzene**  
 $[2.1] C_6H_4(NO_2).CHBr.CHBBr.NO_2$ . [91°]. From  $\omega$ -di-nitro-phenyl-ethylene and Br (Priebs, *A.* 225, 352). White needles, v. sl. sol. ligroin.

**$\omega$ -Di-bromo- $\omega$ -di-nitro-ethyl-benzene**  
 $[4.1] C_6H_4(NO_2).CHBr.CHBBr.NO_2$ . [103°]. From  $\omega$ -di-nitro-phenyl-ethylene and Br (P.). Plates.

**DI-BROMO-NITRO-ETHYLENE**  
 $C_2HBr_2(NO_2)$ . [112°]. From sodium tri-nitro-resorcin  $C_6H(NO_2)_3(OH)(ONa)$  in aqueous solution, and bromine vapour (Merz & Zetter, *B.* 12, 2046). Prisms (from  $CHCl_3$ ); does not combine with Br. Zn and HCl give ethylamine.

**DI-BROMO-DI-NITRO-FLUORESCÉIN**  
 $C_{20}H_6Br_2(NO_2)_2O_5$ . From di-bromo-fluorescein and  $HNO_3$ , or from di-nitro-fluorescein and Br. Yellow needles; is not fluorescent.

**Acetyl derivative** [256] (Baeyer, *A.* 183, 61).

**BROMO-NITROFORM** v. **BROMO-TRI-NITRO-METHANE**.

**BROMO-NITRO-HYDROCINNAMIC ACID** v. **BROMO-NITRO-PHENYL-PROPIONIC ACID**.

**BROMO-NITRO-MESITYLENE**  $C_6H_3BrNO_2$  i.e.  $C_6HBrMe_2(NO_2)$ . [51°]. Formed by nitrating bromo-mesitylene (Fittig & Storer, *A.* 147, 7).

**Bromo-di-nitro-mesitylene**  $C_6H_2Me_2(NO_2)_2$ . [194°]. From di-bromo-mesitylene by fuming  $HNO_3$ . Needles (Süssenguth, *A.* 215, 248).

**BROMO-NITRO-METHANE**  $CH_3Br(NO_2)$ . [114°]. Formed by the action of bromine on sodium nitro-methane (Tscherniak, *B.* 7, 916; *A.* 180, 128 v. **NITRO-METHANE**). Pungent oil. The bromine and nitro-ethyl render its hydrogen displaceable by sodium: it is a strong acid.

**Bromo-di-nitro-methane**  $C_2H_2Br_2(NO_2)_2$ . From di-bromo-di-nitro-methane and alcoholic KOH (Villiers, *BL* [2] 37, 452; Losanitsch, *B.* 16, 51); or from (a)-di-bromo-cauphor and conc.  $HNO_3$  (Kachler & Spitzer, *M.* 4, 558). Oil.

**Salt.** -  $CKBr(NO_2)_2$ . S.G.  $\frac{1}{2}$  1.25; trichlinic crystals which explode at about 147°. Reduction by sodium-amalgam gives HCN, HBr, and  $NH_3$  (Villiers, *BL* [2] 41, 282). Ammonium sulphide gives di-nitro-methane.

**Bromo-tri-nitro-methane**  $CBr_3(NO_2)_3$ . *Bromo-nitroform*. [about 12°]. S.G. 2.8. From nitroform and Br in sunlight; or from mercuric nitroform and Br (Schischkoff, *A.* 119, 247). Decomposes at 140°, but volatile with steam.

**Di-bromo-nitro-methane**  $CHBr_2(NO_2)$ . (155°-160°). Formed by adding bromine to potassic bromo-nitro-methane:

$CHKBr(NO_2) + Br_2 = CHBr_2(NO_2) + KBr$ . Bromopierin, insoluble in potash, is formed at the same time (Tscherniak, *A.* 180, 130). Very pungent oil, volatile with steam, soluble in caustic soda.

**Di-bromo-di-nitro-methane**  $CBr_2(NO_2)_2$ . [c. 0°]. Formed by the action of conc.  $HNO_3$  on tri-bromo-aniline, ethylene bromide, bromophenol, or di-bromo-*p*-toluidine (Losanitsch, *B.* 15, 472; Villiers, *BL* [2] 37, 452). Greenish-

yellow, pungent oil, volatile with steam. Alkalis form salts of bromo-di-nitro-methane.

**Tri-bromo-nitro-methane**  $CBr_3(NO_2)_3$ . *Bromopierin* [10°]. S.G.  $\frac{1}{2}$  2.811.

**Formation.**—From nitro-methane, bromine, and KOH (V. Meyer & Tscherniak, *A.* 180, 122).

**Preparation.**—CaO (4 pts.),  $H_2O$  (50 pts.),  $Br_2$  (6 pts.) and picric acid (1 pt.) are mixed in the order named and the product is distilled (Stenhouse, *P. M.* [4] 8, 36; Groves & Bolas, *A.* 157, 253; *C. J.* 23, 153).

**Properties.**—Pungent prisms, may be distilled *in vacuo*. Converted by Br into  $CBr_3$ .

**BROMO-DI-NITRO-METHYL-ANILINE**  
 $C_6H_4Br(NO_2)_2.NHMe$  [1:3:5:6]. [147°]. From di-nitro-methyl-aniline and Br. Yellow crystals; boiling aqueous KOH gives bromo-di-nitro-phenol (Norton & Allen, *B.* 18, 1996).

**Bromo-nitro-di-methyl-aniline**  
 $C_6H_3Br(NO_2).NHMe$  [4:3:1]. [72°]. Long crystals. Formed together with other products by the action of nitrous acid upon *p*-bromo-di-methyl-aniline (Koch, *B.* 20, 2460).

**BROMO-DI-NITRO-METHYL-DI-PHENYL-AMINE**  $C_{12}H_{10}NBr(NO_2)_2$ . [191°]. Light yellow tables. Formed by bromination of di-nitro-methyl-di-phenyl-amine (Leymann, *B.* 15, 1236).

**BROMO-NITRO-NAPHTHALENE**  
 $C_{10}H_7Br(NO_2)$  [1:4]. [85°]. From (a) bromo-naphthalene and  $HNO_3$ . Yellow needles.  $PBr_3$  gives  $C_{10}H_5Br_2$  [81°] (Jolin, *BL* [2] 28, 515).

**Bromo-nitro-naphthalene**  
 $C_{10}H_7Br(NO_2)$  [1:4' or 4']. [122-5°]. S. (93 p.o. alcohol) 337 at 15-7°. From (a)-nitro-naphthalene and bromine (Guareschi, *A.* 222, 291). Yellow needles (from alcohol).  $KMnO_4$  gives bromo-phthalic acid [174°-176°].

**Bromo-nitro-naphthalene**  $C_{10}H_7Br(NO_2)$  [3:1]. [131°]. From (2,4,1)-bromo-nitro-(a)-naphthylamine by the diazo-reaction (Liebmann & Scheiding, *A.* 183, 262; Meldola, *C. J.* 47, 508). Straw-coloured needles. Exchange of  $NO_2$  for Br gives (1,3)-di-bromo-naphthalene [64°].

**Bromo-nitro-naphthalene**  $C_{10}H_7Br(NO_2)$  [1:3]. [132°]. From (a)-naphthylamine by bromination, nitration, diazotisation &c. (Liebmann, *B.* 8, 1108; *A.* 183, 262). Yellow needles; Sn and HCl give (b)-naphthylamine.

**Bromo-di-nitro-naphthalene**  
 $C_{10}H_6Br_2(NO_2)_2$ . [170°]. Long glistening needles. Formed together with the following isomeric by nitration of (a)-bromo-naphthalene with fuming  $HNO_3$  (1.5). Not attacked by boiling with aqueous NaOH. On oxidation with dilute  $HNO_3$  it gave a small quantity of (a)-nitro-phthalic acid (Merz & Weith, *B.* 15, 2710).

**Bromo-di-nitro-naphthalene**  
 $C_{10}H_6Br_2(NO_2)_2$ . [143°]. Tables or prisms. Formed as above. Not attacked by boiling aqueous NaOH. On oxidation with dilute  $HNO_3$  it gave a little (a)-nitro-phthalic acid (Merz & Weith, *B.* 15, 2710).

**Bromo-tetra-nitro-naphthalene**  
 $C_{10}H_4Br_4(NO_2)_4$ . [190°]. Needles. S. (benzene at 18°) 37. Formed by further nitration of bromo-di-nitro-naphthalene [170°] by heating with a mixture of  $HNO_3$  and  $H_2SO_4$ . It dissolves in caustic alkalis forming tetra-nitro-naphthol.  $NH_3$  converts it into tetra-nitro-naphthylamine, and aniline gives the phenyl derivative of the latter. On oxidation with dilute  $HNO_3$  it gives

di-nitro-phthalic acid [227°] (Merz a. Weith, *B.* 15, 2712).

**Bromo-tetra-nitro-naphthalene**

$C_{10}H_2Br(NO_2)_4$ , [245°]. White glistening needles. Nearly insol. ordinary solvents. Formed by nitration of bromo-di-nitro-naphthalene [143°] with a mixture of  $HNO_3$  and  $H_2SO_4$ . It is attacked by alkalis with difficulty.  $NH_3$  converts it into tetra-nitro-naphthylamine and aniline gives the phenyl derivative of the latter. On oxidation with dilute  $HNO_3$  it gives di-nitro-phthalic acid [200°] (Merz a. Weith, *B.* 15, 2718).

**Di-bromo-nitro-naphthalene**  $C_{10}H_4Br_2(NO_2)$ , [96.5°-98°]. One of the products of action of Br on nitro-naphthalene. Small yellow needles (from alcohol) (Guarreschi, *A.* 222, 286).

**Di-bromo-nitro-naphthalene**

$C_{10}H_4Br_2(NO_2)$  [1:4:1]. [116.5°]. From (1,4)-di-bromo-naphthalene and  $HNO_3$  (S.G. 1:4) in the cold (Jolin, *Bl.* (2) 28, 515).  $PCl_5$  gives tri-bromo-naphthalene [85°].

**Di-bromo-nitro-naphthalene**  $C_{10}H_4Br_2(NO_2)$ , [100°-105°]. From di-bromo-naphthalene [68°] and  $HNO_3$  (S.G. 1:4) (Canzoneri, *G.* 12, 427).

**Tri-bromo-di-nitro-naphthalene**

$C_{10}H_2Br_3(NO_2)_2$ . From (1, 2, 4)-tri-bromo-naphthalene and fuming  $HNO_3$  (Prager, *B.* 18, 2164).

**BROMO-NITRO-(a)-NAPHTHOIC ACID**  $C_{10}H_4Br(NO_2)CO_2H$  [1:4:4']. [260°]. Formed by nitration of bromo-(a)-naphthoic acid [246°]. Small yellowish prisms (from alcohol). Its ammonium salt forms glistening plates, sl. sol. cold water (Ekstrand, *B.* 19, 1135).

**BROMO-NITRO-(a)-NAPHTHOL**

$C_{10}H_3Br(NO_2)(OH)$  [2:4:1]. [136°]. From (2, 4, 1)-bromo-nitro-acetyl-(a)-naphthylamine and conc. NaOH. Silky needles (from alcohol); oxidation gives phthalic acid.

**Salts.**— $C_{10}H_3Br(NO_2)(ONa)$ aq: red needles. —( $C_{10}H_3Br(NO_2)O$ ) $_2$ .Ba 3aq.

**Methyl ether**  $C_{10}H_3Br(NO_2)(OMe)$ , [115°]. Pale yellow silky needles (Meldola, *C. J.* 47, 497).

**Bromo-nitro-(a)-naphthol**  $C_{10}H_3Br(NO_2)OH$ , [142°]. From acetyl-bromo-(a)-naphthylamine by nitration and saponification (Biedermann a. Remmers, *B.* 7, 538).

**BROMO-NITRO-(a)-NAPHTHYLAMINE**

$C_{10}H_3Br(NO_2)(NH_2)$  [2:4:1]. [197°]. From the acetyl derivative by dissolving in conc.  $H_2SO_4$  and ppg. with water. Orange needles; gives phthalic acid on oxidation (Meldola, *C. J.* 47, 497; 43, 9).

**Acetyl derivative**  $C_{10}H_3Br(NO_2)(NHAc)$ , [225°]. From acetyl-(a)-naphthylamine by nitration and bromination. Pale ochreous needles.

**Bromo-nitro-(a)-naphthylamine**

$C_{10}H_3Br(NO_2)(NH_2)$  [1:2:1]. [200°]. From acetyl-(a)-bromo-(a)-naphthylamine by nitration and saponification (Liebermann a. Scheidung, *A.* 183, 258). Oxidized by dilute  $HNO_3$  to phthalic acid. Elimination of  $NH_3$  gives bromo-nitro-naphthalene [132°]. Conc.  $HBr$ aq at 130° gives (1, 2, 4)-tri-bromo-naphthalene.

**Acetyl derivative**  $C_{10}H_3Br(NO_2)(NHAc)$ , [232°].

**DI-BROMO-NITRO-ORCIN**  $C_{12}H_4Br_2NO_2$ , i.e.  $C_6MeBr(NO_2)(OH)$ , [112°]. From (8)-nitro-orcin and Br. Yellow laminae (from alcohol).—

$Ba(C_6H_4Br_2NO_2)_2$  2aq: red needles (Weselsky, *B.* 7, 444).

**BROMO-NITRO-o-OXY-BENZOIC ACID**

$C_8H_4Br(NO_2)(OH)CO_2H$  [5:3:2:1]. *Bromo-nitro-salicylic acid*, [175°]. Yellow needles. Formed by nitration of bromo-salicylic acid in acetic acid solution.— $A'_2Ca$  2aq: V. sol. water.— $A_2Ba$ : yellow needles.— $C_8H_4Br(NO_2)<\begin{smallmatrix} CO_2O \\ O \end{smallmatrix}>Ba$  2aq:
